That Dr. PURVES STEWART'S *Diagnosis of Nervous Diseases* has met with the wide acceptance it deserves is proved by the fact that the second edition has now been published⁶ although less than two years have elapsed since we reviewed the first. The new edition is considerably larger than the first. The extended table of contents has been omitted, but many new diagrams and illustrations have been added, and the whole subject matter, in a department which is continually undergoing revision and addition, has been brought carefully up to date. Professor Marie's views, about which so much has been written, on aphasia—according to which diagrammatic visual, auditory, and speech centres are denied, and aphasia referred to intellectual deficiency from disintegration of some part of Wernicke's zone—are compactly described and opposed. Under cranial nerves there are brief accounts of Bárány's aural or vestibular nystagmus; of "jaw winking" (lid opening in congenital ptosis during certain jaw movements—for example, in mastication), and Harman's explanation of the phenomenon; Mendel's view of the innervation of the orbicularis is discarded. Amongst the upper neurone palsies the differential points between the upper, corticospinal or supranuclear, and the lower or nuclear or infranuclear paralyses are most lucidly discussed, and in the lower neurone group many new illustrations—for example, of ischaemic paralysis, Landouzy-Déjerine myopathy, etc.—are introduced. The chapter on the cerebro-spinal fluid and lumbar puncture has been brought up to date; and, finally, two new chapters—one on sleep and the last on intracranial tumours—have been added. So far, we have mentioned only the facts of which the author treats. It remains to be said that he has the happy gift of giving the gist of a matter in a few pregnant sentences, and of seeing clearly what is wanted, and consequently of being singularly lucid in expression. We can warmly commend this book to our readers.

THE CHEMISTRY OF THE CARBOHYDRATES.

THE work Professor EMIL FISCHER has during recent years been performing on the proteins and polypeptides has no doubt overshadowed his untiring energies in other directions. To those in danger of forgetting Professor Fischer's services to biochemistry in relation to subjects other than the proteins, his thick volume of collected papers will come as a useful reminder.⁷ It is convenient for workers on the same or allied subjects to have the published researches of any prolific worker under one cover, and this is the *raison d'être* of the present volume, as it was that of a similar volume issued a year or two ago on the proteins. To attempt even a superficial review of the great mass of information contained therein is an impossible task. It will be sufficient to remind readers that Fischer's work on the carbohydrates was pioneer and epoch-making, rendering clear their constitution, and making their synthesis an accomplished fact. Each paper is a brick in the edifice of this knowledge which was finally reared. The volume contains 103 papers, mostly by Fischer himself; a few emanate from his pupils, or were written in collaboration with colleagues; 99 of these relate to the carbohydrates directly, and of the remaining

ten which come under the heading ferments, the greater part deal with carbohydrates indirectly. When one remembers that this work extended over about twenty years, and that the same twenty years were occupied with equally important and difficult and illuminating research in other directions, one cannot but be filled with admiration for the great master in Berlin to whom chemists and biologists alike are indebted for so much he has done in the exploration of Nature's secrets by the method of experiment.

PHYSIOLOGY.

THE *Student's Handbook of Physiology*,⁸ begun by the late Dr. ARTHUR CLARKSON, has been completed by Dr. DAVID FARQUHARSON, and published by Messrs. Livingstone. Dr. Farquharson has contributed the chapter on the central nervous system and some of the sections on the special senses. The book is a careful and very well illustrated compilation, but lacks the breadth of modern physiology and that value which the views of a writer would have who was in close touch with the researches of the last few years. For example, we miss any account of the recent work on the regeneration of nerve, and the striking experiments of Langley and others on the grafting of one nerve to another; likewise of the influence of posture on the circulation, an omission which leads to a most insufficient account of the principles which underlie the circulation of the blood; again, the important effects of changes of barometric pressure on the body are dismissed with insufficient notice. An old classification of the proteins is given, and the word "proteid" retained which has been given up by the general agreement of English physiologists. The cause of aphasia is placed in Broca's convolution, as if no Marie or Monikow had arisen to upset the old traditional localization. The book strikes us as mainly a rehash of older textbooks, and to have no features of its own which make it especially commendable to the student. It contains, however, in a clear and concise form as much as he needs to get up to pass his examinations.

We have received the third part of the second volume of the handbook of physiological methods⁹ which Professor TIGERSTEDT is editing. The earlier parts of this useful work have already been noticed in these columns. The present part contains articles on muscle physiology. Dr. K. BÜCKER deals with the thermodynamics of muscle, giving at most inordinate length all the different methods of a dozen workers. The general mechanics of muscle are dealt with by Professor von FREY; the mechanics of special muscular movements by Professor O. FISCHER; the electrophysiology by Dr. S. GARTEN. Professor v. Frey compresses his information into 30 pages, the other three authors manage to fill the rest of a large volume of 488 pages. The whole deals with the duller part of physiological science, and one which is furthest removed from practical medicine, but experts on these particular branches of study will find here full information by thoroughly qualified men.

The instructions for the practical course of general physiology conducted at Glasgow have been published by Professor NOEL PATON in conjunction with Mr. HERBERT CLARK.¹⁰ There is, as far as we can see, little new in the course or any freshness in form which particularly invites the use of these Glasgow syllabuses by other schools of physiology. The whole teaching of experimental physiology urgently wants remodelling in this country. The older experiments on frogs' muscles, etc., can now be replaced largely by a most interesting series of experiments on the circulation, respiration, etc., of the student himself, and amplified by work on the pithed rabbit, the organs of which can be maintained alive by artificial respiration. The student can thus be made familiar with those important problems of the respiratory and circulatory organs which he has to face in his clinical work.

The tables drawn up by W. BEHRNS for the use of microscope workers have proved so useful that they have

⁶ *The Diagnosis of Nervous Diseases*. By Purves Stewart, M.A., M.D. Edin., F.R.C.P., Physician to Out-patients, Westminster Hospital; Physician to the West End Hospital for Nervous Diseases, etc. Second edition. London: E. Arnold, 1908. Demy 8vo, pp. 660, 15s.

⁷ *Untersuchungen über Kohlenhydrate und Fermente* (1884-1908). By Emil Fischer. Berlin: Julius Springer, 1909. (Roy. 8vo, pp. 920, M 24.)

⁹ *Handbuch der physiologischen Methodik*. Edited by Professor R. Tigerstedt. Band 2: 3 Ab. Leipzig: S. Hirzel.

¹⁰ *A Practical Course of General Physiology*. By Noel Paton, M.D., F.R.C.P., and G. Herbert Clark, M.B., D.P.H. Glasgow: G. Maclehoose and Sons, 1908. (Demy 8vo, pp. 39, 1s.)

appeared in a fourth edition, enlarged and improved by E. KÜSTER.¹¹ A number of distinguished workers in Germany, in each branch of the subject, such as Apfathy, Paul Mayer, Schieffedecker, P. G. Unna, Czapski, have contributed to the preparation of these tables. The tables contain all the required information as to weights and measures, specific gravity of and percentage of dissolved substance in solutions of reagents employed, solubilities, refraction coefficients, magnification and apertures, fixing and hardening methods, injection masses, staining methods, culture media and methods of staining bacteria and protozoa, microchemical reagents, microscopical methods for investigating crystals and minerals with the polarimeter, etc. The matter is arranged in a very clear way, so that the practical instructions can be found in a moment.

PHYSICAL CHEMISTRY.

In his *Theory of Valency*,¹² Dr. FRIEND has made a unique contribution to English chemical literature. Curiously enough, in Germany only a single monograph, written by Dr. Henrichsen, has hitherto appeared on the subject. The method adopted by the author has been to discuss a few of the earlier theories of valency, to treat in detail of the elements arranged according to Mendeleef's periodic law, and to conclude with a rather more elaborate review of current ideas. Considerable space has been given to the ingenious and convincing theories of Sir J. J. Thomson, and the author sums up strongly—as, of course, the evidence compels him to do—in favour of the electric view of valency. The juxtaposition of the conflicting explanations shows in a most striking way the difficulty of the whole question, and nothing need be said here further to emphasize the importance to chemical theory of the whole conception of valency being established on a firm foundation. Dr. Friend has done a most valuable service in collating and giving a clear expression to contemporary views. His work will prove of very great service to students in elucidating one of the most important chemical problems with which they are called upon to deal.

In his *Outlines of Physical Chemistry*,¹³ Dr. GEORGE SENTER has made a very valuable contribution to Messrs. Methuen's Textbooks of Science series. The volume has been rendered necessary by the rapidly-growing importance of the subject, and special attention has been devoted to those portions presenting the greatest difficulty to beginners, such as chemical equilibrium, electrical conductivity, and electro-motive force. The book is perhaps hardly suitable, as, indeed, it is not intended, for those who are studying the subject without direction, for the inherent difficulties are not surmounted, despite the trouble Dr. Senter has taken. But, suitably directed, the student will find the work an invaluable guide to the theorems of physical chemistry, which he has usually to study scattered up and down the pages of textbooks of chemistry and physics. A very considerable improvement would be made in the text if Dr. Senter could induce one of his pupils to read it critically, and point out those portions which require amplification. As seems inevitable in a book of this kind, there are a considerable number of misprints. For instance, a few lines from the bottom of p. 46 a bracket has twice been misplaced; on p. 55 a reference is made to the line 'FB' that appears nowhere on the corresponding figure, and so forth throughout the volume. These, however, will doubtless be corrected in a second edition.

NOTES ON BOOKS.

DR. WILLIAM ODELL, in a pamphlet entitled *Treatment of Pulmonary Tuberculosis with Ichthiol*, expresses a favourable opinion of the value of this drug, with which he has treated 123 cases out of the 165 under his care in the Western Hospital for Incipient Consumption, Torquay, since October, 1901. It must be borne in mind that all

these patients have been under "open-air" treatment in a particularly favoured part of England, and that, as Dr. Odell points out, their improvement may be due to the general treatment quite as much as to the ichthiol. However this may be, Dr. Odell's 123 patients showed arrest of the disease in 29; 47 were very much improved, 12 much improved, 18 improved, 5 were "incurable," 2 "unsuitable," 5 unimproved, 1 died, and 4 are still in the hospital doing well. Dr. Odell is convinced that ichthiol tends to diminish the amount of coughing and expectoration, and therefore to minimize the liability to hæmorrhage, and that it reduces temperature and increases appetite. He usually commences with 7½ minims in half a wineglass of water three times a day after food, and gradually increases to 10 drops thrice daily; though he has never gone beyond that dose, he has no doubt that larger doses would be tolerated in many cases. The nauseous taste of the drug can be obviated by giving it in capsules.

Volume xi, part 3, of the *Transactions of the American Ophthalmological Society* for 1908,¹⁴ published recently, contains, as usual, a large amount of interesting material by many writers, most of whom are well known in the whole ophthalmic world. It is a record of the forty-fourth annual meeting of the Society, held under the presidency of Dr. Riseley of Philadelphia. Among the contributors are Drs. de Schweinitz, Holloway, Kipp, Shoemaker, Derby, Millikin, Arnold Knapp, Pooley, Pusey, Bull, Howe, Byers, and Major Henry Smith, I.M.S., who is so well known as the champion of the extraction of cataract within the capsule. He here deals with the extraction of immature cataract by his method. The illustrations are numerous and well done, both the coloured and those in black and white. The subject list ranges over pretty well the whole extent of ophthalmology.

The *Pharmaceutical Pocket Book*, 1909,¹⁵ contains much useful information within a sufficiently small compass to justify the use of the term "pocket book." It is written primarily for pharmacists and pharmaceutical students, but much of the matter presented will be of service to any one interested in the preparation and supply of medicines. Articles on the analysis of water, milk, urine, and metallic salts, and on bacteriological examination of different kinds of materials, appear to be intended principally for those who have studied these branches of work and require a condensed account for handy reference, while the chapters on the science and art of dispensing and on volumetric analysis do not presuppose a knowledge of the subject, and should be of use to students. Much information is given in tabular form, as, for instance, particulars as to origin, constituents, etc., of all drugs in ordinary use, equivalents of metric and imperial measures of length, mass, and capacity, doses of official medicines, etc.; a fairly comprehensive dictionary of synonyms is another useful feature.

Volume I of *The Students' Pictorial Pocket Series*¹⁶ is a little book on somewhat similar lines, but more limited in scope. It contains tables of dose, therapeutic action, solubility, etc., of official and unofficial medicines, a tabular summary of the composition and mode of preparation of galenic compounds, and so on. Much information is condensed into small space, and the employment of abbreviations is carried to the verge of obscurity. As a summary for use in preparing for examinations and for reference in subsequent practical work it will doubtless prove useful.

Dr. GEORGE F. EDWARDS, of Maidenhead, has written under the title *Old Time Paris, a Plain Guide to its Chief Survivals*,¹⁷ a useful little book. Paris has to so large an extent transformed itself into a cosmopolitan city of pleasure that the inexperienced visitor, even if he has no particular desire to indulge in the distractions enumerated by the author in his first page, often finds it difficult to know where to look for old Paris with its old houses and characteristic life. Dr. Edwards tells him where to go and what to look for in a very systematic way, and his little volume will prove an invaluable companion.

Nova et Vetera.

THE FOUNDERS OF THE EDINBURGH BOTANIC GARDEN.

In a book called *Under Petraia*, to which people who care about Italy, and especially those who remember *In a Tuscan Garden*, may be glad to have their attention called, we come across a connecting link between Scotland and Italy which has not, so far as we recall, been noted before in this column. At Padua, where the Admirable Crichton as well as the more famous Harvey were students, there is a botanic garden said to be the oldest in Europe. Now, Mr. Francis Steuart in the *Scottish Historical Review* for October, 1905, in discussing the roll of the university to which many Scots students resorted, mentions the name of one George Sibbald, of whom he says, "He, it is interesting to note, was uncle to the Sir Robert Sibbald who founded the Botanical Gardens in Edinburgh in 1667, and one cannot help connecting this with the mention of John Evelyn, the diarist, of the Garden of Simples, rarely furnished with Plants, which he saw when he too was a medical student at Padua."

There seems to be some doubt as the real share of Sir Robert Sibbald in the foundation of this institution. The first botanic garden in Edinburgh was called the Physic Garden, and lay in the hollow to the east of the North Bridge, on ground now covered by the Waverley Station, in the very bed of what was once the Nor' Loch. The old Physic Gardens remained there, at the foot of the Calton Hill, till they were transferred in 1770 to a spot on the west side of Leith Walk, resting there till 1824, when the present Botanic Gardens and Arboretum off Inverleith Row were formed. The Physic Garden, according to James Grant,¹ owed its origin to Sir Andrew Balfour, the son of Sir Michael Balfour of Denmyne. "An eminent physician and botanist, he was born in 1630, graduated in medicine at St. Andrews, prosecuted his medical studies under the famous Harvey in London, after which he visited Blois to see the celebrated Botanical Garden of the Duc de Guise, then kept by his countryman, Dr. Robert Morison, author of the *Hortus Regius Bloisensis*, and afterwards, in 1669, Professor of Botany at Oxford. In 1667, Balfour began to practise as a physician in St. Andrews, but in 1670 he removed to Edinburgh, where, among other improvements, he introduced the manufacture of paper into Scotland. Having a small botanical garden attached to his house, and chiefly furnished with rare seeds sent by his foreign correspondents, he raised there many plants never before seen in Scotland. His friend and botanical pupil, Mr. Patrick Murray, of Livingstone, had formed at his seat a botanic garden containing fully a thousand specimens of plants; and after his death Dr. Balfour transferred the whole of this collection to Edinburgh, and, joining it to his own, laid the foundation of the first botanic garden in Scotland, for which the magistrates allotted him a part of the Trinity Garden, and then, through the patronage of Sir Robert Sibbald, the eminent physician and naturalist, Mr. James Sutherland, an experienced botanist, was appointed head gardener. After this Balfour was created a baronet by Charles II. He was the first who introduced the dissection of the human body into Scotland; he planned the present Royal College of Physicians, projected the great hospital now known as the Royal Infirmary, and died full of honours in 1694, bequeathing his museum to the University." The *Dictionary of National Biography* (iii, 48) gives us the additional information that Balfour visited both Bologna and Padua, where no doubt he saw the Botanic Garden.

Although Grant gives the chief credit of the foundation of the Physic Garden to Balfour, there is nothing in the whole statement to show that Sir Robert Sibbald—and possibly his uncle, George Sibbald, with his memories of the famous gardens at Padua—did not have a hand in the business. Sir Robert certainly appointed James Sutherland the superintendent of the garden. Sutherland was a gardener, and "seems," writes Grant, "to have been one of those self-made men of whom Scotland has produced so many of whom she may well be proud." In 1683 Sutherland published his "*Hortus Medicus Edin-*

burgensis, or a catalogue of the plants in the Physic Gardens at Edinburgh, containing the most proper Latin and English names," dedicated to the Lord Provost, Sir George Drummond. "In his little garden in the valley of the North Loch," continues Grant, "he taught the science of herbs to the students of medicine for small fees, receiving no other encouragement than a salary of £20 from the city, which did not suffice to pay rent and servants' wages, to say nothing of the cost of new plants, so difficult to procure in those non-travelling times."

In 1689, during the siege of the Castle, it was deemed necessary to drain the North Loch, with the result that the poor little Physic Garden was nearly washed away in the flood; it had at any rate all its precious plants covered with rubbish and mud. In his distress Sutherland appealed to the Privy Council, who, considering the good services he was rendering, "whereby not only the young physicians, apothecaries, and surgeons, but also the nobility and gentry, are taught the knowledge of herbs, and also a multitude of plants, shrubs, and trees are cultivated which were never known in this nation before, and more numerous than in any other garden in Britain, as well for the honour of the place as for the advantage of the people," awarded him a pension of £50 yearly out of the fines accruing to them. The Lords of the Scottish Treasury further aided him, and he was able to extend his operations to a piece of ground near Holyrood Palace, where, in 1695, he raised "a good crop of melons, other curious annuals, fine flowers, and other plants not ordinary in this country." James Sutherland had another hobby, for, in 1705, when he died, his collection of Greek, Roman, Scottish, Saxon, and English coins and medals was purchased by the Faculty of Advocates, and is still preserved in their library. In the *Edinburgh University Calendar* James Sutherland takes his place at the head of the list of the Professors of Botany, a list which ends with the name of Isaac Bayley Balfour, the present Professor and Regius Keeper of the splendid Botanic Gardens and Arboretum (covering about sixty acres) in Inverleith.

Little is heard of the Physic Garden for some years after the death of Sutherland. Probably, like many other things in the city, it suffered from the blight which fell upon Edinburgh after the union of the Scottish and English Parliaments. There were, however, Professors of Botany, Charles Preston and George Preston, and in 1738 Charles Alston became Professor of Medicine and Botany, the title which the chair bore until 1879, when John Hutton Balfour was succeeded by Alexander Dickson, who took again the old name of Professor of Botany. But the Garden became famous once more in 1761, when Dr. John Hope was appointed King's Botanist for Scotland, and when he was made by the Town Council Professor of Materia Medica and of Botany. Seven years later he resigned the professorship of the former subject in order to devote himself entirely to botany. He taught his students in the Physic Garden; but, finding that it was unsuited to the rapidly-advancing importance of the subject, he appealed for funds for a new garden, and succeeded in getting enough money from the Lords of the Treasury and the Town Council to acquire and lay out the new garden to the west of Leith Walk. Professor Hope introduced into Scotland the Linnean system, which had been opposed by his predecessor, Dr. Alston.

Hope, in his botanical garden, has been made a familiar figure to after-ages by Kay in his *Portraits*. A German traveller, named Frank, paid a visit to the new garden in 1805, and said, in praise of the plants: "I saw a beautiful *Ferula asafœtida* in full bloom; the gardens at Kew receive their plants from this garden." The present Botanic Garden and Arboretum in Inverleith, with its palm house, 100 ft. high, its rock garden, and its museum, all under the care of Professor Bayley Balfour, would indeed delight the eyes of that other Balfour who did so much, with the help of Sibbald and the example of Padua, to found its modest forerunner of the seventeenth century in the valley now given up to one of the largest railway stations in the world.

THE late Dr. Peter Horrocks, President of the Obstetric Society, London, left estate of the gross value of £40,207, with net personality £39,422.

¹ *Old and New Edinburgh*, vol. i, p. 362.

THE COMPOSITION OF CERTAIN SECRET REMEDIES.*

XIII.—INEBRIETY CURES.

PARTICULARS are here given of the results of the analysis of certain nostrums which are advertised for the cure of the drink habit. These form a somewhat distinct class from the "treatments" and "systems" in which, ostensibly at least, individual cases are dealt with according to their particular nature or peculiarities. The last of the remedies here described approximates to the class just referred to.

COZA POWDER.

Supplied by the Coza Institute, 76, Wardour Street, London, W., formerly 62, Chancery Lane, London, W.C.

Price 10s. per box, containing thirty powders.

This preparation is advertised with an offer of a free sample. An application for a sample brought a single powder together with a 10s. box to be paid for or returned, a book of 130 pages (which is referred to below), and a letter, from which the following is an extract:

Coza Powder has the marvellous effect of producing a repugnance to intoxicating drink of any kind, and may be administered in coffee, tea, milk, water, beer, whisky, brandy, or solid food without the partaker's knowledge.

Coza Powder does its work so silently and surely that any person interested in the intemperate can administer it to him or her without his or her knowledge and without him or her learning what has effected the transformation.

Coza Powder has reconciled thousands of families, saved from shame and dishonour thousands of men and transformed them into sturdy citizens and capable business men. It has led many a young man along the direct road to good fortune, and has prolonged by several years the lives of many individuals.

We particularly wish to draw your attention to the fact that we guarantee Coza Powder to be absolutely harmless.

The book which was sent, entitled *No more Drunkenness*, opens with the statements that

Coza Powder is one of the greatest discoveries of the day. There is nothing in the whole world to compare with it. It is the only powder to cure the craving for drink and drug habits.

The first few pages are devoted to a disquisition on drunkenness; then follow further claims for Coza Powder, such as

Coza is the name of a marvellous powder which possesses the quality of occasioning in him who takes it a dislike for alcoholic liquors and all intoxicating drinks. The drinker finds alcohol so detestable that even on the most tempting occasions it will be impossible for him to take a single drop.

A large part of the book is given up to what are called testimonials, with portraits stated to represent the writers; the large majority of these are dated from Continental countries. Those to which English names and addresses are appended are for the most part expressions of hopefulness, or records of little variations in drinking which are believed to be due to the powders; for instance:

My friend has been taking "Coza" this last two days, and he has had no desire for drink.

Enclosed you will find P.O. for which send me another box. I think the powders are doing my friend good. Send at once.

The last pages of the book are devoted to advertisements of Canexia Hair Elixir, Canexia-Brilliantine, and Canexia-Shampoo Powder, supplied from the Canexia Chemical Works, 61, Chancery Lane; and Anticelia Tablets for Obesity, and Brixia Tablets for Thin People, supplied from 62, Chancery Lane.

A visit to the address showed that the Canexia Chemical Works, the Coza Institute, and the offices of Anticelia and Brixia Tablets were all accommodated in three rooms on the second floor at 61 and 62, Chancery Lane, the double number representing one entrance of a large block of buildings containing hundreds of different offices. A photograph of the entire block, inscribed "Coza Institute," is given in the book just referred to. The address has since been changed to that given above.

The powders had an average weight of 1½ grain, the weights of single ones varying from ½ grain to 3 grains. Analysis showed them to contain sodium bicarbonate, 90.5

per cent., the remainder being a vegetable powder; microscopic examination of this powder showed that it agreed in all its characters with a mixture of equal parts of cummin fruits and cinnamon. No alkaloid was present, and no other ingredient of any kind could be detected. The formula is thus:

Sodium bicarbonate...	...	90 parts.
Powdered cinnamon...	...	5 "
Powdered cummin...	...	5 "

Estimated cost of ingredients for 30 powders, one-thirtieth of a penny.

DIPSOCURE.

Prepared by the Carlton Chemical Co., 43, Guildhall Buildings, Birmingham.

Price 9s. per box, containing 50 powders, 25 being white, and 25 tinted reddish-buff.

This article, like the preceding, is advertised with an offer of a free sample. Application for a sample brought also a stream of letters at short intervals, with abundant printed matter. A few extracts from the letters are here given:

Eminent medical men have over and over again declared that if a cure for drunkenness could be discovered both TASTELESS AND ODOURLESS, and placed in the hands of a devoted woman to administer SECRETLY, the greatest difficulty in effecting cures would have been overcome. "Dipsocure" IS TASTELESS AND ODOURLESS, and CAN BE administered SECRETLY: so that it has been our privilege and good fortune to have solved the problem. Whilst counteracting and freeing the alcoholic-laden system of the poison, it is soothing to the nerves and restores the health, and is harmless to the most delicate person.

No matter how great the drunkard, or how many years he or she has been so, "Dipsocure" will absolutely and permanently cure any ordinary case, and transform the drunkard into sober, kind, generous, and loving men and women.

... two packages have been usually found sufficient (and frequently one), in the most severe cases of confirmed drunkards, to bring about a speedy and permanent cure.

Most drunkards imagine they suffer from some ailment, such as rheumatism, indigestion, headache, constipation, etc. No matter what it is they complain of, administer Dipsocure as the ostensible cure, and be certain of the result. It cannot harm the most delicate constitution of either man or woman, of what-ever age, even if an overdose is taken: we guarantee this most distinctly. The preparation contains no poisonous or injurious drugs of any kind.

In a short time after use the sufferer will regain nerve power, improved appetite and health, and all alcoholic beverages will become absolutely nauseous to them—they will even shrink from the smell of them.

It acts through the blood, permeating every part of the system, disseminating (sic) and driving out the alcoholic poison, which cannot resist its action, completely restoring the patient to health, strength, and renewed vigour. IT KILLS alcohol. The cure is as complete as it is certain and the patient REMAINS PERMANENTLY CURED.

... when a cure has been effected we ask you to kindly acquaint us of the fact, and perhaps you will then consider our agency proposal, showing how a good income can be made by introducing the cure to others. To show you the ease with which it can be sold, if you remit us 10s. three packages will be sent, two of which you can readily dispose of to other sufferers at 9s. each, thus making 8s. profit and obtaining one packet quite free.

The directions for use are:

Give one powder three times a day, before meals, dissolved in half a tea-cup of Hot Coffee, Tea, Whisky, Milk, Gin, etc. Use either the brown or white powder, as the colour of the liquid may require.

The powders had an average weight of 4.2 grains, single powders varying from 2.9 to 6.0 grains. The composition of both kinds was found to be the same except for the trace of colouring matter contained in the tinted powder. Analysis showed the composition to be—

Acetanilid...	...	6 parts.
Potassium bromide...	...	35 "
Sugar of milk...	...	59 "

Estimated cost of ingredients for 50 powders, one-third of a penny.

ANTIDIPSO.

Supplied by the Ward Chemical Company, 205, Regent Street, London, W.

Price 10s. per box, containing 48 powders, 24 being white and 24 tinted pinkish-buff.

The statements made about this article, in circulars and

* Previous articles of this series were published in the following issues of the BRITISH MEDICAL JOURNAL:—1904, vol. ii, p. 1585; 1906, vol. ii, pp. 27, 1645; 1907, vol. i, p. 213; vol. ii, pp. 24, 160, 209, 393, 530, 1635; 1908, vol. i, pp. 833, 912, 1375; vol. ii, pp. 86, 565, 1022, 1110, 1153, 1285, 1566, 1691, 1875; 1909, vol. i, p. 31.

letters, are very similar to those made about the preceding one. A few extracts will suffice:

You will not forget that to insure an absolute complete and permanent cure for the craving, two boxes are invariably required. We have had data of cures effected with one box, but to make absolutely sure you will do well to immediately send us remittance, to the same value as the last, and get the second box of the specific.

Antidipso may be administered with or without the knowledge of the patient.

Should the patient be suffering from any trifling ailment such as indigestion, a rheumatic twinge, slight headache, or constipation, administer a powder in hot tea, coffee, or milk. No matter what the complaint may be, give Antidipso as the ostensible cure.

We enclose you a booklet showing our agency terms. Kindly give it your attention as we are confident you will be so surprised and satisfied at the cure which will be effected that you will either yourself want to take up agency with us, or get someone in your district to do so.

The directions are:

Give one powder, dissolved in half a tea-cup of hot coffee, whisky, milk, gin, etc. (using either Brown or White Powder as colour of fluid may require) 3 times a day before meals.

The powders had an average weight of 5.3 grains, single powders ranging from 3.7 to 9.9 grains. The white and tinted powders were made of the same constituents, with a trace of colouring matter added in the latter case, but in different proportions. Analysis showed the composition to be:

WHITE POWDERS.			
Potassium bromide	24.5 parts.
Sugar of milk	75.5 "
COLOURED POWDERS.			
Potassium bromide	35 parts.
Sugar of milk	65 "

Estimated cost of ingredients for 48 powders, one-third of a penny.

THE TEETOLIA TREATMENT.

Supplied by the Teetolia Treatment Association, 97, New Oxford Street, London, W.

The following are extracts from the advertisement of this preparation:

After Years of Drink and Drug taking—
Cured in 4 days.

... The Teetolia treatment acts so rapidly and so efficiently that within four days from the commencement of administration the insistent craving for drink is absolutely destroyed—so much so, that even the thought of alcohol becomes nauseating. ... Thousands have been cured by this treatment, and we guarantee to cure you. ... If you write to-day, addressing the Teetolia Treatment Association, 97A, New Oxford Street, London, W.C., you will receive by return of post a private consultation sheet, together with a valuable book on this subject, post free in plain envelope, and you will be a free man within a week.

On application being made for further particulars, a booklet of twenty pages, entitled *The Teetolia Treatment for Alcoholic Excess, Drug Habits, and Resultant Nervous Diseases*, was sent, together with a letter and a form to be filled up with particulars of the case to be treated. The following are extracts from the booklet:

It has at last become recognised that the craving for drink, with its subsequent gratification is a disease, and can only be combated and overcome, like all other diseases, by scientific medical treatment.

This is not the place to discuss or pass judgment upon the various Licensing Acts introduced and passed into law by successive Governments. Whatever their merits or demerits may be, we are faced to-day with the stern fact that the consumption of drink and, consequently, the number of drunkards, with the exception of temporary fluctuations, are increasing yearly—in other words, that this terrible disease is extending and widening, carrying with it wherever it goes havoc, misery, want, and the destruction of domesticity. Nor does the disease die with its victim: the mysterious law of heredity comes into operation, and from generation to generation the disease is passed on from father to son, until finally, owing to its degenerating and pernicious influence, the family becomes extinct.

The discovery of the Teetolia method and treatment for the permanent eradication of the crave for drink and drugs marks an era in medical science. It is the outcome of a life's study of the subject by one of our best known West End physicians.

You can, whilst undergoing the treatment pursue your ordinary methods of living. You continue to take your daily modicum of alcohol; but somehow about the third or fourth day

of treatment, without having made any physical or mental effort, you feel that you no longer want a drink; it holds out no attractions to you; its magnetic influence has gone. You can't understand it. You have not been actively resisting or fighting the craving, so far as you know; but Teetolia has been fighting for you. It has been producing its effect upon your nerve tissue, exercising its invigorating influence upon your brain, restoring healthy tone to your debilitated stomach, creating a normal, instead of a depraved, appetite, and so, not by the aid of any magic spell or philtre, but with the assistance of a discovery, purely scientific and rational, working in a natural way.

We are willing to supply you with sufficient medicine for eight days' treatment FREE of all charge. This will enable you to determine whether the treatment is acting successfully, for at the end of the fourth day an obvious and perceptible effect should be experienced. We impose no condition; we rely on your candour, honesty, and gratitude that at the end of the eight days' treatment, if you are convinced of the value of the Teetolia Treatment, you will forward to us the ordinary fee—£1.1s.—for same, but if you have derived no benefit from the treatment at the end of the same period, then you are under no obligation whatever to pay us one single penny.

The letters were on headed paper, at the top of which was printed, "All communications strictly confidential," and "Consultations with Physician by appointment." The first letter concludes as follows:

Please therefore fill in and return without delay the special statement sheet and upon our receiving it the Physician will go carefully into the case and will prescribe special medicine, which will reach you with expert advice in the course of two or three days in a perfectly plain sealed package.

The "special statement sheet," with the answers given printed in italics, was as follows:

CONFIDENTIAL PARTICULARS OF CASE.

Case No.

1. Age and Sex of Patient. *Male, 34.*
2. If married, what Family, if any? *Yes; two children.*
3. What class of stimulants is generally taken—Drugs, Beer, Wine, or Spirits? *Spirits.*
4. Has the habit been recently acquired; if not, how long established? *Nearly two years.*
5. Mention average daily quantity taken. *About a bottle of brandy.*
6. Is the habit persistent or intermittent? If the latter, mention ordinary duration of intervals. *Usually 2 or 3 days a week with very little drinking; and there have been two complete intervals of 3 or 4 weeks each.*
7. What are height and weight of patient? *5 ft. 9; 11 stone.*
8. Is the patient putting on flesh or otherwise? *No particular change.*
9. Is constitution generally healthy? *Yes.*
10. (a) Does the patient enjoy a good appetite? *Yes.*
(b) Is the digestion good? *Fair.*
11. Does the patient suffer from sleeplessness? *No.*
12. (a) As far as you know is the heart sound? *Yes.*
(b) Does the patient suffer from any organic malady? *No.*
13. Is temperament nervous or phlegmatic? *Nervous.*
14. Has patient ever suffered from any serious illness? If so, state nature of same. *Typhoid, fourteen years ago.*
15. Is there any family history of alcoholism? *One uncle is a drunkard.*
16. Has patient ever suffered from—
(a) Any form of epilepsy? *No.*
(b) Delirium tremens? *Once (perhaps more).*
17. Has the patient ever—
(a) Submitted to any other form of treatment for alcoholism? *No.*
or
(b) Been an inmate of an Inebriates' Home? *No.*

Fill in here any further information concerning case that the Physician should be in possession of—

Patients and their friends may rely with perfect confidence on all particulars of this case being regarded by the Association as strictly private.

The "expert advice," in a letter purporting to be from "The Medical Superintendent," sent with the medicine, contained these passages:

I want if possible, the patient to use his own endeavours to try and keep off alcohol during the first few days of treatment if this cannot be done, then the treatment must be commenced when the patient is not drinking, in order to give the medicine a better hold on the system. The dislike for alcohol, which we claim, does not come on all at once.

The eight days' treatment is enough to show you that it will do good, but, not sufficient in this case to effect a permanent cure. I would advise the patient to continue for at least a month to six weeks.

This is somewhat widely at variance with the statements quoted above, "You continue to take your daily modicum of alcohol" and "you will be a free man within a week."

The one-guinea "treatment" consisted of 2½ fluid ounces of a liquid of the nature of a vegetable fluid extract.

The directions were :

Half a teaspoonful to be taken in a little water every four hours during the day at 10, 2, 6, and 10 o'clock.

Analysis showed this to contain 29.3 per cent. by volume of alcohol, and 2.3 per cent. of alkaloid, which consisted principally of quinine. The liquid agreed generally with a diluted liquid extract of cinchona; the amount of alkaloid is just under half what is contained in the official liquid extract of cinchona. In addition, treatment with suitable solvents extracted a trace of a non-alkaloidal bitter substance resembling the bitter substances obtainable from quassia, chiretta, etc.; these substances, however, do not possess well-marked characters by which they can be identified like alkaloids, and it was not possible to ascertain the drug from which this was derived; a preparation of chiretta appeared to be the more probable. No strychnine was present, and no evidence was obtained of any other ingredient.

THE PERCENTAGE OF NICOTINE IN VARIOUS KINDS OF TOBACCO.

PROFESSOR DIXON MANN, in an article published recently in the JOURNAL (December 5th, 1908, p. 1673) on some of the effects of excessive smoking, pointed out that recent investigations have afforded strong evidence that, contrary to the view very generally held in the past, nicotine is by far the most important constituent in producing the characteristic effects of tobacco smoke.

One fact which seems to have been established by these researches is that only a portion of the nicotine of the tobacco passes unchanged into the smoke, the greater part being destroyed by the heat; according to two of the investigators quoted by Dr. Mann the ratio of the nicotine in cigar smoke to the nicotine originally present in the cigar is liable to vary widely in the case of different brands of cigars. But after allowing for such variations it would appear to be true as a general proposition that the more nicotine there is in a cigar or any other form in which tobacco is smoked, the more the smoker is likely to take into the system. It is, therefore, of some importance to know the relative amounts of nicotine contained in different kinds of tobaccos. Further, if the results of such an inquiry show that the percentage of nicotine rises and falls *pari passu* with the character of the tobacco as "strong" or "mild" when judged by a smoker, collateral evidence will be afforded of the correctness of the view that the effects of smoking are principally due to the nicotine.

In previously published determinations of the amount of nicotine in tobacco, the methods employed have varied considerably, and in some cases, at least, their accuracy is very much open to question. A discussion of various methods would be out of place here; but the process employed in the analyses, of which the results are given below, must be briefly described.

A known weight of the tobacco was mixed with slaked lime and distilled in a current of steam until alkaloid was no longer to be found in the distillate; a rather prolonged distillation was necessary to reach this point, giving a rather large volume of distillate. The latter was then rendered decidedly acid with sulphuric acid and evaporated to a low bulk; the nicotine was then liberated by the addition of fixed alkali, and extracted by shaking out with six successive portions of ether; the aqueous liquid was reserved for further treatment. The ether solutions were mixed, and freed from any adhering fixed alkali or ammonia derived from the tobacco, by washing with a small quantity of water; water was then added, and the alkalinity of the ether solution (due to nicotine) was determined by titration with standard alkali. Methyl orange was added to the liquid to act as indicator; but, as the end point of the titration is by no means well marked, litmus paper was also used as a subsidiary indicator, small drops being taken out and tested at intervals; from the result of the titration the amount of nicotine was calculated, but, in view of the unsatisfactory end point, this result was not relied on. The liquid, now containing the nicotine as sulphate, together with sulphate of any alkali used in checking the end point, and of any

ammonia from the tobacco that had not been removed by the washing, was evaporated to dryness on a water bath, and the nicotine sulphate dissolved out from the dry residue by means of absolute alcohol, leaving other sulphates undissolved. The alcoholic solution was evaporated to dryness, and the residual pure nicotine sulphate weighed; the corresponding quantity of nicotine was calculated from this weight, and was always found to be lower than the quantity calculated from the titration. The aqueous liquid which had been extracted with ether was found to retain a small quantity of alkaloid; it was accordingly acidified, and precipitated volumetrically by titration with Mayer's solution, the nicotine equivalent of which was ascertained by titrating a solution of pure nicotine in the same way. The end point is not well marked, so that it was only found possible to obtain approximate results; but, as the amount of nicotine determined in this way is only a small fraction of the total, the error so introduced is but small. The amount of nicotine found by this titration was added to the larger amount previously found. Control determinations made with pure nicotine showed that (after making this addition) the result deduced from the titration was rather too high, while that obtained by weighing the nicotine sulphate was too low, owing to loss of nicotine during the drying of the sulphate. The mean of the two gave a tolerably correct result, and the figures given below are such mean values.

PERCENTAGE OF NICOTINE IN PIPE TOBACCOS, CIGARS, AND CIGARETTES.

	Nicotine per cent.
<i>Pipe tobaccos :</i>	
A. Very mild honey dew ...	1.65
B. Smoking mixture, medium strength ...	2.04
C. Perique ...	3.29
D. Cavendish ...	3.83
<i>Cigars :</i>	
E. Havana, mild ...	1.09
F. Havana (same maker), strongest ...	1.58
G. Havana (another maker), "mild" ...	1.95
H. Indian, strongest ...	1.84
I. "Patent non-nicotinic" (German) ...	0.58
<i>Cigarettes (after removing paper) :</i>	
K. Egyptian ...	1.13
L. Turkish ...	1.30
M. Virginian ...	2.24
N. Common, five a penny ...	2.02

Of the pipe tobaccos, Perique and Cavendish are the strongest varieties obtainable, and are usually employed only for mixing with other kinds. The cigars taken for examination were all of good quality, and (except I) of well-known brands. G is the only case in which the result is strikingly at variance with what might be expected. This was a light-coloured cigar, and was supplied by a large firm of tobaccoists as the mildest cigar they kept in stock; but in the opinion of a smoker, although certainly mild in flavour, it produced more effect on the heart than most mild cigars. The cigarettes, except N, were of good quality and well-known brands. In view of the fact that ill effects from cigarettes are sometimes ascribed to the paper, this was separately examined. The fibre of which it is composed was practically the same in all four cases, and appeared to be a mixture of flax and hemp. None of the papers, however, consisted of pure fibre, and examination of the ash gave the following results:

	Percentage of Ash.	Metals found in the Ash.
Egyptian (printed with brand in bronze letters)	7.0	Copper (0.2 per cent. of weight of paper), aluminium, iron, magnesium, calcium.
Turkish (printed with brand in bronze letters)	10.7	Copper (0.8 per cent. of weight of paper), aluminium, zinc, iron, magnesium, calcium.
Virginian (printed but not in bronze)	8.8	Aluminium, iron, magnesium, calcium, sodium, potassium.
Common (printed but not in bronze)	8.8	Trace of lead; iron, magnesium, calcium.

THE THERAPEUTIC APPLICATIONS OF RADIUM: METHODS AND RESULTS.

A NOTE ON THE THERAPEUTIC APPLICATION OF RADIUM.

By J. M. H. MacLEOD, M.A., M.D., M.R.C.P.,

PHYSICIAN FOR DISEASES OF THE SKIN, VICTORIA HOSPITAL FOR
CHILDREN; ASSISTANT PHYSICIAN TO THE SKIN
DEPARTMENT, CHARING CROSS HOSPITAL.

The advances which have been made recently in radium-therapy have been the result chiefly of the improved technique of application adopted by our French colleagues, in which, instead of the radium salt being applied in a glass tube or aluminium box, it is spread by means of a varnish on a metal or stiff linen surface. The suggestion of varnishing the radium on to a flat surface is an old one, and was made in 1905 by M. Danlos. It is to M. Danne, however, that we are indebted for an efficient varnish, which, while firmly fixing the radium salt to the surface of the metal, is unaffected by the action of the atmosphere, moisture, and ordinary antiseptics. The composition of this varnish has so far been kept secret. It is the sulphate of radium, either pure or diluted with sulphate of barium, which is fixed by the varnish, this salt being chosen in preference to the bromide of radium as it is insoluble, while the bromide is readily soluble.

The advantages claimed for the French method of application are:

1. That by it practically all the rays from the radium are available, the less-penetrating rays not being intercepted by the glass, mica, or aluminium windows of the older "applicators," and

2. That with a given quantity of radium a much larger radio-active surface is obtained, over which the radio-activity is evenly distributed.

The first of these advantages would seem, as far as our knowledge goes at present, to be of considerably less account than the second, for by the mica or aluminium screen only the alpha rays and the softer beta rays are cut off, while the hard beta and gamma rays to which radium probably owes its selective action on diseased tissues are not intercepted. Indeed, doubts have been cast on the capacity of the alpha rays to penetrate even the varnish. According to Professor Soddy's opinion, as expressed in a recent issue of this JOURNAL, "in the absence of any definite physical tests proving that the alpha rays are capable of getting through this coating, the natural presumption would be that they were completely absorbed." On the other hand, Wickham and Degrais have repeatedly asserted that a proportion of alpha rays are emitted by the varnished surface. It is customary, however, to interpose a thin layer of gutta-percha between the varnished surface and the skin to prevent soiling the specimen, and this procedure effectively cuts off the alpha rays. Again, different screens of lead, aluminium, etc., are sometimes employed so as to intercept all but the highly penetrating gamma rays, as in the case recorded by Dominici and Bory, where an epithelioma of the lip, the size of a five-franc piece, was dispersed by radium, only the gamma rays being allowed to act upon it, so that, after all, the presence of the mica or aluminium screen in the old applicators may prove to have been no disadvantage.

The case is very different with regard to the second advantage of the French method—namely, the increased extent of radio-active surface. It has been estimated that when spread out 1 cgr. of a radium salt of an activity of 100,000 has approximately the same effect on the tissue as 5 cgr. of a salt of an activity of 600,000 collected in a small mass in a glass tube. To get the full value of a given quantity of radium salt it is necessary to have it spread evenly over a surface, and, within certain practical limits, the larger the surface the better. By means of Danne's varnish the sulphate of radium has been perfectly spread and fixed on metal surfaces of different shapes and sizes. It is a different matter, however, with the bromide of radium, for, being soluble,

it is unsuitable for varnishing. In this country those who have been using radium therapeutically during the last six years have chiefly employed the bromide, and they are presented with the difficulty of having it spread. I am aware that it is possible to have the bromide transformed into the sulphate, but there is a certain risk of loss in this process. There is another way, however, of dealing with the matter which is fairly satisfactory, and that is the simple expedient of having the radium bromide crushed down to a fine powder, and evenly spread and pressed in the thinnest possible layer between a metal back and a thin aluminium or mica window. I recently had 5 mgr. of pure radium bromide removed from an applicator, where it was in the form of small amorphous lumps, crushed down and spread in the above manner over a circular area 1 cm. in diameter. On examining it with a platino-barium-cyanide screen, the fluorescence was almost if not quite as great over the whole surface as it had been in the much smaller area presented by it before it was spread, and its therapeutic value was found to be proportionately greater than before.

In this way there is no great difficulty in constructing flat "applicators" of different shapes and sizes in which the radium bromide, either pure or mixed with a definite quantity of some inert salt, is thinly spread over a flat surface. For example, I have had a locket-shaped applicator made with a narrow frame and a mica window 2 cm. square, in which 1 centigram of pure radium bromide may be mixed with 3 centigrams of the inert salt, and the mixture evenly spread over an area corresponding to the window, so that each square centimetre contains 1 centigram of the radium bromide mixture of a radio-activity of 500,000.

By the use of such "applicators" one of the advantages, probably the main one, of the French method can be obtained in the case of the bromide, without having it exchanged for the sulphate, which at present is 25 per cent. more costly, or running the risk of having it transformed into the sulphate, and this can be accomplished in a manner in which the radium salt is completely protected by being fixed in an applicator, instead of being exposed to friction and possible loss, as it is when varnished on a metal surface.

TREATMENT OF ANGIOMATA.

[FROM OUR PARIS CORRESPONDENT.]

In two preceding articles in the BRITISH MEDICAL JOURNAL (March 6th, p. 609; March 27th, p. 797) the broad lines of the various methods employed by Drs. Wickham and Degrais in radium-therapeutics have been described; the results obtained in certain maladies will now be considered. The progress realized in the treatment of angioma is one of the most interesting. Drs. Wickham and Degrais, whose conclusions are founded on about 350 cases, state that the results are extremely favourable in the projecting, but more difficult to obtain in the superficial and flat forms. The following case is reported as one of the most extraordinary:

The life of a baby a few months old was in danger on account of the size and the number of vascular tumours which covered its face; one situated on the lower lip was very large, violet, and filled with blood, swelling up at the least exertion. It spread on to the buccal mucous membrane, and made feeding extremely difficult. The lip hung down, and was useless for suction; the child had to be fed with a spoon. There was another tumour on the upper lip, blocking the two nostrils to such an extent that the child breathed badly and incompletely. The right eye was completely hidden by two vascular tumours, one on the upper and the other on the lower eyelid, which touched and closed the right eye. These tumours affected the conjunctiva as much as the skin surface. The right ear was blocked by an enormous vascular tumour, which had developed in front of the ear, completely blocking the external canal, the meatus itself extending into it. These were the principal tumours, but there were others. All were raised above the surface; some were covered with normal healthy skin, in others the skin was violet. The child, then thin and puny, was brought in this condition two years ago to Dr. Wickham; treatment was commenced and the child was then transformed. The eye is freed, respiration takes place normally, the lip has almost regained its natural form, the violet discolorations have entirely disappeared and traces of the projecting tumours can be found only on looking very closely. The case shows the superiority of radium over all other methods of treatment, for neither surgery, x-rays, nor electrolysis could have attempted to cure a case of such gravity. The treatment

was simple, but required great patience. Each tumour, where-
 over possible, was treated by the method of "cross-fire," an
 apparatus being placed above and another below. In this case
 the apparatus chosen were of feeble intensity, and placed bare
 on the tumours, being left in contact with the tissues for a time
 shorter than could cause any surface irritation; for instance,
 knowing that a certain apparatus would cause irritation of
 the surface if applied for twenty minutes, it was only left in
 position for ten minutes. Owing to the "cross-fire," the
 tumour was thus affected in its interior as by a single applica-
 tion of twenty minutes. The applications were made each day
 for ten days, followed by ten days' rest. When it was not
 possible to employ "cross-fire" the apparatus was applied
 directly on the tumour for as long as was possible without
 causing any irritation. All the angiomata diminished in size,
 and the face was restored to a natural appearance.

This was an extreme case, but Drs. Wickham and
 Degrais have treated by the method of "cross-fire"
 numbers of patients who only had a single tumour, which
 was cured without any irritation of the skin.

When angiomatous tumours affect the skin proper, it is
 sometimes of advantage to produce a slight irritation of
 the surface, but not when the tumour is completely sub-
 cutaneous. The following case has a great practical and
 scientific interest from this point of view:

A young girl, 15 years of age, had a vascular tumour in the
 substance of the right cheek, without any violet discoloration
 either of the skin or of the mucous membrane; the swelling
 looked as if the girl had placed a nut between the jaws and the
 cheek; the face was deformed, and was quite asymmetrical.
 The diagnosis of a vascular tumour was made because the swelling
 was soft, was increased by exertion and diminished by pressure.
 In this case, as treatment by "cross-fire" was indicated, one
 apparatus was placed on the mucous membrane, and the second
 on the skin surface. The length of the applications was chosen
 so that neither of the surfaces was inflamed; the apparatus
 placed externally on the cheek was covered with a sheath of
 lead 2 mm. thick, so that only rays of great penetrating power
 were employed. The treatment was carried out in four series,
 each at two months' interval. Each series consisted of ten
 applications, one apparatus being applied to the skin surface
 for twelve hours each day, the other to the mucous membrane
 of the cheek for one hour each day; the latter apparatus was
 covered with lead 1 mm. thick. At the present time the
 appearance of the cheek is almost normal and similar to the
 other one. The calibre of the blood vessels has been reduced
 without the slightest irritation of the skin.

The superiority of radium over other therapeutic methods
 seems still more clearly shown in the following case:

A baby had a raised vascular tumour of the upper eyelid
 spreading over the eyebrow and a portion of the forehead. The
 tumour had been excised by a surgeon of undoubted ability but
 re-formed a month later, becoming even larger than before. It
 was then treated by cauterization, with the result that it
 became smaller but returned. This relapse was treated by
 electrolysis without any appreciable result. Radium treatment
 was then suggested, but the case was in a bad condition for
 treatment by radium, inasmuch that the operation had pro-
 duced hard, sclerotic, cicatricial tissue. In spite of that radium
 had quite a surprising effect, the tumour diminished without
 inflammation, and for the past year it has been level with the
 surface.

When port wine marks are superficial and not raised
 above the surface, Drs. Wickham and Degrais use
 apparatus of feeble radio-activity but of comparatively
 large surface; gradual discoloration is obtained by the
 repetition of the applications. They advise that the treat-
 ment should be specially applied to those forms that are
 deeply coloured and infiltrated. Up to the present time, at
 least, they do not advise treating those forms which are
 very superficial, and especially very pale in colour. The
 latter can be easily concealed by the use of toilet
 preparations, and the results of treatment are not
 sufficiently marked.

SANITARY APPLIANCES.

An Antiseptic Dust-Preventer.

THE watering of roads with a solution of calcium chloride
 for the purpose of preventing dust rising appears to be
 meeting with considerable success, and a useful applica-
 tion of the same method for employment in sweeping rooms
 has been made by Dismo, Limited (West Ham Lane, Strat-
 ford, London, E.). This firm has submitted samples of
 two materials which they prepare under the names
 "Dismo" and "Lydus," respectively for use on carpets
 and on linoleum or boards, etc.; a line of the material is
 spread on the floor at the place where sweeping is to be
 begun, and this is then swept forward as the work pro-
 ceeds, the effect being to prevent dust rising, and to

retain it in close mixture with the sweeping material,
 where it is acted on by antiseptic constituents. Practical
 trials showed that the materials answered their purpose
 in a very satisfactory manner; examination showed them
 to consist of mixtures of sand and sawdust containing
 calcium chloride, together with a substance yielding
 formaldehyde on exposure, and fragrant terpenes. Such
 a material may prove of great use in hospitals and sick
 rooms, and possesses considerable value for ordinary
 domestic purposes.

MEDICAL AND SURGICAL APPLIANCES.

A Squint Reader.

THE Squint Reader illustrated is designed by Dr. Arthur
 Greene, of Norwich, to provide a strong and not expensive
 apparatus by which repeated and long-continued binocular
 use of the eyes may be ensured during the treatment of
 concomitant squint in children able to read, the vision of
 whose squinting eye has by exercises and the aid of appro-
 priate lenses been brought up or nearly up to that of the
 "fixing" eye. The general plan of the apparatus can be
 seen by a glance at the illustration. By placing a book on
 the bookholder, with the middle of the page to be read

(not the middle of the book) opposite the middle of the
 apparatus, the sliding "interruption block" can easily
 be moved to such a position that, on the child looking
 through the sight-hole end, it is impossible to read the
 lines of the book unless exercising true binocular vision.
 The features of the apparatus are: (1) its strength; (2) its
 portability—it can fold so as to be almost flat; (3) the book-
 holder is constructed to hold almost any kind of book or
 magazine; (4) it can be used with ordinary story books
 instead of fixed figures or letters, of which the most up-to-
 date child would soon tire; (5) its cheapness, enabling it
 to be used for hospital patients. The ideas of the designer
 have been faithfully carried out by Messrs. F. Davidson
 and Co., of 29, Great Portland Street, London, W.

LITERARY NOTES.

THE Boston Medical Library, we learn from the *Boston
 Medical and Surgical Journal*, has arranged a series of
 exhibitions illustrating various epochs in the history of
 medicine. The first includes collections of works of the
 Hippocratic era and the School of Alexandria; the second
 Roman Medicine and the Byzantine Period; the third
 Arabian Medicine and the School of Salerno; the fourth
 Monks and Scholastics and the Pre-Renaissance; the
 others the medicine of the sixteenth, seventeenth,
 eighteenth, and nineteenth centuries respectively. The
 Boston Medical Library possesses many rare volumes and
 manuscripts relating to medical science. We hail with
 pleasure the signs manifested in different countries of the
 awakening of an interest in the history of the development
 of medical science.

To the *Contemporary Review* for March Mr. E. L.
 Butcher contributes an interesting article entitled "The
 Exorcism of Hydrophobia." He prefaces it by the state-
 ment that hydrophobia was introduced into Egypt at the
 time of the British occupation by a dog belonging to an
 Englishman. This led to the revival of a custom in the
 Egyptian Church which implies that rabies must have
 been known in Egypt in early Christian Ages, and Mr.
 Butcher thinks it probable that the ceremony as now
 performed is the adoption and sanctification of what
 had been an attempt in ancient Egypt to treat patients
 suffering from hydrophobia by hypnotic suggestion,
 at the same time isolating and guarding them. The

ceremony, as described to Mr. Butcher by an Egyptian who had taken part in it, is as follows: The case was one of a child whose mother applied for help to the narrator's uncle. She was instructed to rise early on the morning of the next day, being Saturday, bake seven thin loaves of bread and prepare a handful of dry dates. Neither she nor the patient was to eat anything that day till the ceremony was over. On Saturday the narrator got up at five o'clock in the morning, and packed up in a small cloth bag a small censer, two phials—one full of the church wine, the other of anointment oil—and the book containing the ritual. He had also to collect six other children of his own age to take part in the ceremony. The rite began with the recital of the Lord's prayer: then incense was offered with the prayer of thanksgiving. Next came the prayer for the sick, after which the fifth chapter of the Epistle of St. James and the seventh of St. Luke were read in Arabic and in Coptic. After three short prayers had been said the Apostles' Creed was recited by all present. They then made a ring round the patient, and the celebrant, standing outside the ring with a silver cross in one hand, proceeded to read the story of the martyr Abu Tarbo and his encounter with a mad dog. The story is as follows:

When Theodosius the Just came to power he ordered that all persecutions should cease, and religious liberty should be granted to Christians. Consequently all the instruments of torture were destroyed, the gates of prisons were opened, and the prisoners who were convicted on account of their religion were released. Amongst these prisoners was the famous saint, Abu Tarbo. He was set free, and while he was on his way home a fierce mad dog rushed upon him, opening wide his jaws. Abu Tarbo trembling with fear, knelt down, lifting his eyes towards heaven, and without moving his lips or raising his voice, cried out unto the Lord; and the Lord heard him. By a sudden inspiration and courage he rose up, stepped towards the dog, and struck him dead with a stick that was with him. A moment after he heard a voice from above saying, "Tarbo, I give thee the power of healing all those who are bitten with rabid animals." He then thanked the Lord, and proceeded on his way again, repeating, "Thou shalt not be afraid for the terror by night, nor for the arrow that flieth by day, for the pestilence that walketh in darkness, nor for the destruction that wasteth at noonday. A thousand shall fall at thy side, and ten thousand at thy right hand, but it shall not come nigh thee." It happened that a few weeks after this incident the only son of a widow, who lived at the same village where Abu Tarbo lived, was bitten by a rabid dog. The widow took her son and went to him. Abu Tarbo performed this ceremony: anointed the child with sacred oil, sprinkled upon his face consecrated water, and gave him seven mouthfuls of unleavened bread and dry dates, telling him that he should take no more than one mouthful a day. After the lapse of seven days the child recovered from this terrible disease, and was able to come to him on the seventh day and thank him.

Mr. Butcher says that by Theodosius the Just no doubt is meant Theodosius the Spaniard, who became Emperor of Rome in 379 A.D. It is probable, however, that this curious practice is a survival from Pagan times, which may have been first sanctioned and adapted to Christian uses by the saint whom the story calls Abu Tarbo. The ceremony concluded with a long prayer. Whenever the word "dog" occurred in the prayer the celebrant struck a china bowl with a stick as if he was driving away an evil spirit. One of the children barked and howled as this was done. Then the children formed a fairy ring and circled round the patient seven times, reciting a spell consisting of verses from the psalms. They then sat down without breaking the ring. The celebrant thereupon took the towel with the unleavened cakes and dry dates off the child's neck, and after rubbing them with the sacred oil and wine made the children bite off pieces. Before biting, each child was told to walk on his hands and feet, and to bark and snarl as much like a dog as he could. Then portions bitten off the cakes were given to the patient to eat, one each day. He was then rubbed on forehead, chest, and wrists with oil, and the holy water was sprinkled about his bedroom. After seven days the child was back among his companions. The Egyptian says that he often took part in this ceremony, and it was always successful, but he judiciously remarks:

It may have been that the patients were bitten by animals that were not really mad, or, if they were bitten by rabid animals, they might have recovered by the effect of the action of the ceremony upon the patients' minds.

We may add that at the shrine of St. Hubert in Belgium, a method of treating hydrophobia by religious rites is, or

was till lately, practised. It is on the character of that saint as a mighty hunter before the Lord that his cult as a healer of rabies is founded.

MEDICAL INSPECTION AND AFTER.

LONDON.

MEDICAL TREATMENT OF SCHOOL CHILDREN.

At the meeting of the London County Council on April 6th the debate on the report of the Education Committee, recommending the subsidization of hospitals and dispensaries in order to provide medical treatment for school children, was resumed, but, on the ground that no estimate as to probable cost had been presented, the motion by the Chairman of the Finance Committee to refer the report back to ascertain the cost of treating each disease was accepted.

Dr. SALTER moved to add an instruction to the Committee to bring up a scheme for the establishment of school clinics, arguing that hospitals in London were so distributed that they could not provide medical treatment for the children in many districts. Medical opinion, as represented by the British Medical Association, and dental opinion also, were in favour of school clinics. Dr. Salter quoted Dr. Kerr's estimate that twelve clinics could be established for £20,000 per annum.

The CHAIRMAN interrupted further quotations by ruling that members must not quote from a report of an officer who had not been accepted by the committee concerned, and so it came about that the only figures which the Council had before it were contained in an estimate by Mr. A. A. Allen, M.P., who pointed out that medical men were employed by the Council at present for quarter time—nine hours a week—for £150 a year. From this he calculated that in twelve clinics 70,000 to 80,000 dental cases could be treated per annum, and about half that number of eye cases at a cost of about £25,000 a year. Mr. Allen thought the Council should consider very carefully before it introduced a system of rate-aid for hospitals. It was unfortunate, he said, that no estimates prepared by the medical officer were before the Council, for the wildest rumours were going about. One member suggested to him privately that the cost of treating teeth alone would be about £200,000 a year. Clinics in the long run would be cheaper and more efficient.

Mr. BRAY objected to the proposal to make grants to juvenile friendly and other benefit societies for purposes of medical inspection. The result would be, he said, that the Council's teachers would be canvassing on behalf of benefit societies and for the ultimate extinction of the private practitioner.

The Moderate view was expressed by Mr. C. U. Fisher and Mr. Ernest Gray.

Mr. FISHER looked with suspicion upon the employment of medical men and dental surgeons by the Council. If small fees were paid at first they always tended to increase. Mr. C. U. Fisher glanced back to the Education Act of 1870 as the first step in the direction of "undermining parental responsibility." This question of medical treatment should "only" be considered from the point of view of cost.

Mr. ERNEST GRAY seriously distrusted the estimates of cost presented by the medical profession. They had taken, he said, a very strong and narrow trades-union attitude in this matter. One northern borough sent an advertisement to a medical journal for an officer to carry out medical inspection, and the journal refused to insert the advertisement because the salary was not high enough. The sum offered was £300 and it was said that it must be £500.

The amendment was lost by 75 votes to 42.

Dr. BEATON moved a further amendment directing the committee to prepare immediately a scheme for medical treatment, taking advantage of institutions which existed, and for establishing school clinics where other provision was inadequate. He urged that if the two methods of dealing with the question were adopted the Council would be able to cover the whole need and find out from actual experience which was the cheaper.

This amendment, however, was lost and the report, as already stated, referred back.

THE new pathological block at St. Bartholomew's Hospital will be opened by the Lord Mayor, who will be accompanied by the Sheriffs, on Friday, May 7th, at 3 p.m.

British Medical Journal.

SATURDAY, APRIL 10TH, 1909.

MR. TROUTBECK AS THE SURGEON'S FRIEND.

LESS than a year ago we had occasion to comment—not for the first time—on the extent to which the Coroner for Westminster and the South-West District of London magnifies his office. In the JOURNAL of June 13th, 1908, we published a report of a case in which death had occurred in the Bolingbroke Hospital after an operation for the removal of a tumour of the cerebellum. The operation was performed by Sir Victor Horsley; it was done with the full consent of the patient; death would have been inevitable after a few months of wretchedness if it had not been performed; and the reputation of the surgeon gave assurance that it was done with the utmost skill. In the face of these facts Mr. Troutbeck insisted on holding an inquest, as the result of which he directed that a verdict of "Accidental death" should be returned. In commenting on the case we pointed out that in holding this inquest Mr. Troutbeck had gone altogether outside the powers conferred upon him by the Coroners Act, 1887. In Section 3 of that Act it is provided that an inquest shall be held "where a coroner is informed that the dead body of a person is lying within his jurisdiction, and there is reasonable cause to suspect that such person has died either a violent or an unnatural death, or has died a sudden death of which the cause is unknown." Mr. Troutbeck attempted to justify his arrogation of a right, which is not, as far as we know, claimed, and which is certainly not exercised, by other coroners, by the plea that "a death that has been accelerated by an operation cannot possibly be said to be a natural death." He went on to say that a considerable proportion of deaths which undoubtedly were in great part due to surgical operations were never reported to the coroner. They were certified, and owing to our system of certification the certificates were accepted. The registrars did not forward them to the coroners, as he thought they should, because they were not fully aware of the obligations of the Act of Parliament. He was convinced that the result was that throughout the country we were in a complete state of ignorance as to what proportion of deaths were accelerated by surgical operations. It was a serious matter and one for which a legal remedy was undoubtedly required. He regarded it as extremely important from the public point of view, and in these matters the coroner represented the public, on whose behalf such cases ought to be inquired into. They could leave these questions to no profession whatever, however honoured or however skilled. He expressed the intention of not letting the matter stand. These remarks, together with his general practice—as to which Lord Halsbury said that his impression of it was not favourable—were not unnaturally taken to show that Mr. Troutbeck, for some unknown reason, had thought fit to take up an attitude of hostility, or

at least of malevolent neutrality, in regard to the profession. But it appears that we have been mistaken, and that the coroner for the South-West District is in reality the doctor's friend, and in particular is anxious to shield the operating surgeon from blame, and to vindicate his ways to men through the medium of the enlightened juries whom he directs.

Mr. Troutbeck made his first appearance in this new character at two inquests held not long ago, reports of which are published elsewhere in the present issue. In one of the cases a patient suffering from cancer of the bladder was operated on by Mr. Sampson Handley. It was explained to the patient beforehand that the operation was extremely dangerous, but he elected to take his chance. Death took place shortly after the operation, which, if successful, might have prolonged the man's life for years; had nothing been attempted for his relief, the only prospect before him was a brief period of miserable existence. The coroner was pleased to express the opinion that there could be no doubt Mr. Handley was justified in undertaking the operation in the circumstances, and the jury obediently returned a verdict of "Accidental Death." The other case was that of a boy with peritonitis probably caused by appendicitis; the bowel was gangrenous for a length of 10 to 12 inches. As there was just a possibility of saving the child's life, Mr. Swainson operated. Death, however, took place soon afterwards. Here again Mr. Troutbeck came forward as the surgeon's friend, and decided that the operation was fully justified, whereupon the jury returned a verdict of "Accidental Death." In one of the cases he said that these inquiries were primarily for the benefit of the public, and he was good enough to add that they were perhaps of even greater benefit to the operators, who were given this opportunity of showing that they had taken the right course. He went on to say that it was a great satisfaction to them to hear a jury express approval of their efforts at a public inquiry! We fear that they, like ourselves, may have misconceived Mr. Troutbeck's friendly intention. But, indeed, it would seem that he has been wholly misjudged. The profession had not suspected that Mr. Troutbeck is a humorist. What has been taken for the insolence of office was humour. The idea that a leading surgeon should be gratified by the approval of his work expressed by a coroner's jury is truly comic. Now that we understand Mr. Troutbeck, we see that the absolution gratuitously bestowed by him upon surgeons who have done their best in almost hopeless circumstances is not impertinence but friendly fun.

Nevertheless, we take leave to think that he is not happy in his choice of occasion for his jokes, and that they are rather beneath the dignity of his high office. The surgeons may well pray to be saved from so over-zealous a friend. If, with the most benevolent intentions, inquiries are to be held on every case in which a coroner may think fit to assume that death has been hastened by an operation, a number of lives that might otherwise be saved will be sacrificed, and a still larger amount of suffering that might be averted will have to be endured. No surgeon will care to submit his highly skilled workmanship to the judgement of men utterly incompetent to form an opinion on its value. The art of surgery, too, will necessarily suffer, as we have more than once pointed out, if operations that must, from the very nature of the case, be more or less in the nature of desperate remedies for desperate diseases are to expose the

surgeon to the criticism of ignorance and, it may be, prejudice.

The points to be noted in both the cases reported in our Medico-Legal column, is that in each of them the patient was doomed to certain death within a short period of time. In one the operation may have accelerated the fatal issue by two or three months; in the other by about as many hours. In each case every consent that was necessary was given, and in each case the relatives were fully satisfied that everything possible had been done to save life and prevent future suffering. In each case, too, the operator was a surgeon of experience and proved skill and judgement, and there is probably not another coroner in the country who would have wasted public money and the time of busy men—to say nothing of the annoyance caused to the relatives—by holding an inquest. The inquiry was quite unnecessary, and did no good to any one, except to those to whom it was a source of profit in the shape of fees.

The point, therefore, to be determined is not whether the surgeons were, in Mr. Troutbeck's opinion, justified in operating, but whether the coroner was justified in holding an inquest when there was absolutely no reasonable cause to suspect that the death was violent or unnatural. Mr. Troutbeck, as we have seen, holds that if death is accelerated by an operation it cannot be called "natural." We should like to know by what legal casuistry such a death can be called "accidental." Inquests are held as a matter of course on cases in which patients have died after an operation performed to remedy the effects of an accident, but in such cases it is the accident, not the operation, that forms the object of inquiry. There is nothing whatever in the Coroners Act to justify Mr. Troutbeck's extension of the meaning of the words "unnatural death." If this interpretation of what constitutes an unnatural death is to be accepted, a coroner may assume that in any given case death was accelerated by medical treatment; and if he has Mr. Troutbeck's tender regard for the reputation of the profession, he will hold an inquest in order that the doctor may have an opportunity of showing that "he took the right course." On the other hand, inquests on deaths occurring among the Peculiar People, or under the hands of Christian Scientists and faith-healers, should be regarded as unnecessary, because they are in the strictest sense "natural."

It is to be hoped that the Departmental Committee now sitting will once for all settle the question of a coroner's authority in such cases. In a recent debate at the Medical Society of London, Mr. Walter Spencer, who was himself some time ago a victim of Mr. Troutbeck's high-handed procedure, pointed out that the difficulties which had arisen between coroners and medical practitioners were partly due to the difference in the education which formed the legal as distinguished from the medical mind, and which often made it difficult to find a common ground upon which to argue. This is true, and the only way to avoid the difficulty is that only men who have had a medical as well as a legal training shall be appointed to the office of coroner. If any further argument in favour of this proposal were required, it is to be found in the procedure adopted by Mr. Troutbeck. The profession would probably rather have him as an open enemy than as a friend in disguise. In any case a man with so eccentric a notion of humour is out of place as a judge of the serious and difficult work of operating surgeons.

THE "CURE" OF CANCER WITHOUT OPERATION.

WE have repeatedly found it necessary to deal with new suggestions for the treatment of cancer, and each time it has unfortunately been our duty to return a verdict "not proven." No excuse is needed for returning to this subject, for the terrible nature of the disease, its appalling frequency, and our helplessness in dealing with it, all render every attempt to discover a method of treatment which offers some hope to the patient without subjecting him to undue risk, not only laudable but necessary. It is the function of a medical journal to apply criticism of new ideas in such a manner that the profession, and through it the public, shall be safeguarded against risky procedures and false hopes. The busy practitioner has neither the leisure nor the opportunity to examine all the evidence available when a new cure of cancer is announced; but if a method of treatment that offers any serious prospect of efficacy is discovered, he should be enabled to apply it without loss of time and with the full knowledge of its action, its risks, and its limits of effectiveness. In dealing with a hitherto practically incurable disease, any new method of treatment must be accompanied with irrefutable proof, otherwise it cannot in the interest of the sufferers be accepted.

In the task of guiding the profession with regard to the so-called "cancer cures" Professor Zangemeister¹ has recently come to our assistance. In summing up the subject, the Königsberg professor says that if the matter be regarded critically we must come to the conclusion that no method has yet been suggested by which cancer can be cured with anything like the certainty of the knife. Improvements such as the modification of the growth of malignant tumours have been achieved by many and varied means. But although single cases of benefit from such means would suggest that cure could easily be obtained, more extended experience has proved this not to be the case.

There are three ways in which malignant disease might be cured. The first is the attempt to destroy the cancer cell. On theoretical grounds the difficulties in this direction lie in the fact that all agents so far discovered which exercise a deleterious action on the cancer cell exert a similar action on the normal cell, though it may be to a less extent. The means at our disposal at present include heat, cold, magnetic and electric waves, light, Roentgen and Becquerel rays, certain chemical substances, and a number of ferments. Of the physical means, radium has certainly produced the most marked results on superficial growths. Tesla currents (fulguration) are said by some to effect cures, but before this claim can be allowed more evidence must be forthcoming. Of the chemical bodies, arsenic, mercury, and other inorganic substances have been suggested. Zangemeister has tested the effect of injections of cholin, one of the organic compounds proposed, and states definitely that, although a certain amount of cell necrosis can be produced by its means, it does not exercise any curative effect. Of the ferments, he speaks chiefly of trypsin. The theoretical basis on which the trypsin treatment of cancer is built contains too many unknown factors to be accepted as sound. The results obtained in practice fall short of cure, and do not even hold out a promise of success in the future. He has nevertheless tested the effect of trypsin in a few

¹ *Dent. med. Week.*, November 15th, 1908.

cases, and found that no beneficial effect whatever could be discerned. Further, he raises the question whether the injected trypsin in one of his cases did not so injure the nutrition of the cancer as to render it an easy prey to a streptococcal infection, of which the patient died. Apart from the disappointing experience at the bedside, it has recently been shown by Achalmé, von Bergmann, Guleke, and Baumbert that injections of trypsin are immediately followed by the production of antitrypsin, so that an effect opposite to that aimed at is produced. The bile of oxen and other animals has also been tried with the same object, and, unfortunately, with the same negative result. As ineffective, in Zangemeister's opinion, are applications of nuclein and other drugs which produce leucocytosis. Bier's heterogeneous blood treatment has also not led to satisfactory results.

The second way of attacking the problem is to employ a medicament which shall have the effect of specifically dissolving the cancer cells. Cytolysins against carcinomatous cells have been produced by Schöne and others in mouse carcinoma. The difficulties in the way of applying this form of treatment in human disease depend on the uncertainty of the production of antibodies when heterogeneous antigens are employed. All the attempts in this direction have hitherto been unavailing, but the idea is not hopeless, and the future alone will show whether a passive immunization is not possible. Recently the author has attempted to use cancer cells of tumours removed from other patients, or even from the same patient, to overcome the heterogeneous nature of the antigen. The possibility of achieving success by immunizing monkeys has also been suggested, and must be followed out further.

The third way of dealing with the matter is by attempting to neutralize the products of the carcinomatous tissue. Apolant believed that the results obtained in mouse carcinoma by partial immunization, the type changing more and more to non-malignant adenoma, could be explained on the assumption that a gradual change occurred in the character of the cell owing to neutralization of the products. Many workers have determined that abnormal ferments exist in carcinoma. Neuberg considers that radium acts by destroying the cancer ferments. Hofbauer went so far as to suggest employing antitrypsin to inhibit ferment action generally. The weakness of this and similar theoretical forms of treatment depends on the impossibility of attacking cancer ferments alone without affecting the necessary ferments of the vital organs. A mass of hypotheses has been built up on these lines; but the groundwork is too insecure to pick out the sound from the imagined, and it is therefore premature even to hope that fruit will be borne on the branches of such a tree.

The conclusion of Zangemeister's discussion of a large number of proposals for the treatment of carcinoma is that up to the present no non-operative treatment of cancer has been devised which offers a patient a reasonable chance of cure. In other words, all the reputed cures have failed, and the investigators must continue to work before a cure can be found.

INSPECTOR-GENERAL JAMES PORTER, C.B., M.D., Director-General of the Medical Department of the Navy, has been appointed Honorary Physician to the King, in place of the late Inspector-General Sir J. W. Reid, K.C.B., M.D.

THE ANNUAL MEETING AT BELFAST.

AN inquiry has reached Belfast from an inland English county as to the possibility of visitors to the Annual Meeting having an opportunity of seeing the launch of one of the great steamships for which the shipyards of the city are famous. No doubt many others besides the member who made the inquiry will be interested to hear that the local executive has great hopes that such an opportunity may occur. A large vessel for the Orient Line is at present on the stocks in Messrs. Workman, Clark, and Co.'s yard, and is expected to be launched in July. The exact date cannot be settled so far ahead, but if the firm can make it coincide with the visit of the Association to Belfast they have courteously promised to do so. The Ulster Medical Society has arranged to present to the British Medical Association a cup, to be known as the "Belfast Cup," to be played for at Annual Meetings, and to be won out and out by any member winning it three times. It will be played for on the Friday of the Belfast Meeting, on the fine links of the County Down Club at Newcastle, co. Down, kindly lent for the day by the council and members of the club. The play will be by "bogey" score. The cup is designed after the famous Ardagh Cup, one of the finest examples of ancient Irish work, which is now in the Kildare Street Museum in Dublin. The original is composed of gold, silver, enamels, and jewels, and was, it is believed, meant for use as a chalice. The challenge cup will be of silver, about 9 in. high, with gilt panels and coloured enamel bosses; round it will be set stones representing the four provinces of Ireland—the black pebble for Leinster, the white or Carnmoney pebble for Ulster, the red stone for Munster, and the green Connemara marble for Connaught. The North of Ireland Cricket Club, the premier club of Ulster and one of the best in Ireland, has kindly offered to play a one-day match against a British Medical Association team. The beautifully turf-ed grounds of the club are only about five minutes' walk from Queen's College, where the Association will meet. The local executive will be very glad if some English cricketer will undertake to organize a team for the occasion; any one interested in the matter should communicate with one of the honorary local secretaries, whose addresses will be found in the SUPPLEMENT.

INSURANCE FOR MEDICAL MEN.

WITH a view to facilitating insurance by medical men against various risks, about two years ago a Medical Insurance Committee was formed to offer certain special advantages and concessions to medical men. Under an arrangement with the Guardian Assurance Company, Limited, an old-established office, policies of various kinds are issued, including the following: (a) Combined policy against fire, burglary, and the liability of the Workmen's Compensation Act in respect of servants; (b) liability of practitioners for accidents to persons employed in the practice; (c) personal accident and disease; (d) life assurance with or without profits, also endowment and partnership life assurance; (e) fidelity guarantee; (f) glass. A meeting of the committee to consider the annual statement of accounts for the year ending December 31st, 1908, was held last week, when it was reported that the life business had shown a marked and satisfactory improvement, and that there had been a steady increase in other directions, although in respect to employers' liability the improvement had not been so marked as had been anticipated, since it was largely owing to the provisions of the Workmen's Compensation Act, 1906, that the committee was constituted. When that Act became law it was at once perceived that its

provisions would affect medical men not only in the way in which all private members of the community were affected, but also in certain special directions in the exercise of their profession, and the committee, as has been said, insures medical men against liability for accident to persons employed in the practice. We believe that the terms offered by the committee are exceptionally advantageous; it is in a position to make an allowance of the nature of a bonus on the premiums, while the experience gained by the Secretary renders it possible to save the medical insurer a great deal of trouble. It is, we feel sure, desirable that the members of the medical profession both in town and country should more generally make provision against personal illness and accident. Experience proves that owing to exposure to infection and to inclement weather they are specially liable to certain types of disease which are apt to produce their incapacitating effects at that most inopportune moment when there is much sickness in the community. Further, whether he drives a horse-drawn vehicle or a motor car, or mounts the humbler motor or push-bicycle, the risk of personal accident can never be eliminated. Finally, there is probably no profession in which a man's earnings, and even his financial prospects, may be so seriously diminished by the enforced idleness caused by accident or illness. Further particulars can be obtained on application to Mr. Guy Elliston, Secretary, Medical Insurance Committee, 429, Strand, London, W.C.

THE EDUCATION OF MOTHERS.

A VERY novel legislative proposal, called the Necessitous Mothers (Assistance) Bill, was introduced by Mr. Robert Harcourt last week in the Commons. It proposes to empower local authorities to make provision for the assistance of necessitous women in contemplation of and after childbirth. The root idea of the bill is to reduce infant mortality by feeding, instructing, and supervising poor ignorant mothers. The bill is wholly permissive. The local authority can, if it likes, provide food, advice, or other assistance to a poor mother before and for six months after the birth of the child. As a condition for receiving help, it may insist on the mother nursing the child herself, or attending a class for instruction, or refraining from going to work. The municipal expenditure is limited to a penny rate. In an interesting article on the bill the *Manchester Guardian* points out that Mr. Harcourt's proposal is founded on experience gained at Ghent, where the infant mortality was very high on account of the mothers being mostly employed in the textile industry of that district. A local physician, Dr. Miele, started a school for mothers, where working-class women were given advice and instruction before and after confinement and encouraged to suckle their children. The municipality gave a grant of £60 a year to the work, and much good has resulted from the teaching that it is more useful to feed the mother and encourage her to suckle her child than to facilitate bottle feeding by the municipal supply of humanized milk. The Ghent idea was taken up a few years back in St. Pancras, and a school for mothers was founded. Dr. F. J. Sykes, the medical officer of health, earnestly supported the movement in face of the high infantile death-rate, and has had the satisfaction of seeing a great reduction in mortality from the crusade in favour of teaching and feeding the mothers and the encouragement of breast nursing. A similar movement is active in Manchester, but the expenditure is of necessity considerable, and it all falls at present on private philanthropy. Mr. Harcourt's bill would bring the municipality into the work, and we cannot conceive

a more useful expenditure of public money than this attempt to educate mothers in their natural duties and thereby reduce the terribly high infantile death-rate of many industrial centres.

THE MICROBE OF TRACHOMA.

NEARLY two years ago Professor Greeff published a paper¹ in which he stated that, working with the ophthalmic surgeon Dr. Clausen, and the bacteriologist Professor Frosch, he had, in the cells and secretion of the mucous membranes attacked by trachoma, come across small bodies which might possibly be the causal parasites of the disease, though more evidence on the point was required. With the financial support of the Prussian Ministry of Education, he has been able to continue the work on a large scale, and now² definitely asserts that the bodies are the causal parasites of trachoma. The importance of such a discovery is evident, and although Professor Greeff warns readers not to draw too sweeping conclusions, and asks the medical world to work patiently for further evidence with regard to the nature of the bodies in question, it is only reasonable to look a little ahead, and to anticipate the direction which the development of this research must take. In Berlin, Posen, Königsberg, Westphalia, Austria, Japan, and Russia, workers have found the same structures in trachomatous mucous membranes and secretion, and in these alone, and Professor Greeff states that a very extensive series of conditions other than trachoma has been subjected to rigid examination, and in not a single case have these little round coccus-like bodies been found. Dr. Leber has found the granules in 90 per cent. of the trachoma cases he examined in Bovigno. With regard to the suggestion that the bodies are not parasites but protoplasm granules or other forms of cell degeneration, or even the precursors of goblet cells, Professor Greeff says that this was considered from every point of view by him and his colleagues, and was amply disproved. He does not give the evidence in detail, but from the description and the illustrations of the structures, such an explanation does not appeal to the critic as probable. The structures are minute slightly ovoid bodies, considerably smaller than the smallest of the known cocci. At first these bodies are seen sparsely scattered in the protoplasm of the epithelial cells. They are surrounded by a distinct areola, and tend to group themselves in pairs. In the next stage they are seen bordering on the nucleus of the cell, and are accompanied by a sort of flake of protoplasm, not unlike von Prowazek's fibrin masses. When followed a stage further, collections or heaps of the bodies are seen. At first, these heaps are surrounded by a pale zone; later, this "mantle," as he terms it, disappears; lastly, the heaps burst through the mantle, and the small bodies escape into the surrounding cells or secretion. The structures are most easily recognized in the "heap" form. It is not easy, however, to demonstrate them until practice and patience have taught the observer how the specimens are best prepared. The staining is carried out by Giemsa's solutions, according to the following formula: (1) 12 parts of Giemsa's eosin solution (2.5 c.cm. of a 1 per cent. French solution of eosin in 500 c.cm. of water); (2) 3 parts of Azure I (1 in 1,000); and (3) 3 parts of Azure II (0.8 in 1,000). The secretion, together with some epithelial cells, are removed from the conjunctiva by means of some suitable instrument and spread thinly on slides. After drying in the air, the films are fixed for twenty to thirty minutes in absolute alcohol. They are then

¹ *Berl. Klin. Woch.*, June, 1907.

² *Dent. med. Woch.*, March 25th, 1909.

stained for six to nine hours at 37° C. in the solution, washed with distilled water, dried carefully with filter paper, and mounted in cedar oil. The same bodies have been described independently by Halberstädter and Prowazek, and these observers have confirmed the observations of Greeff and his co-workers. That, after a long search, the parasites should be found by two sets of independent observers simultaneously is not strange, since these bodies have been rendered recognizable by improved microscopical and bacteriological technique which is common property. One more fact is brought out in the article of Professor Greeff. After treatment with copper sulphate, long before the trachoma can be said to be cured, the bodies disappear from the superficial cells and secretion. Greeff suggests that they disappear into the deeper layers, where they are still capable of existing and giving rise to pathological changes. Culture of the parasites and reproduction of the disease still remain to be accomplished. We have therefore to determine whether the frequent—in fact, almost regular—occurrence of the bodies in trachoma cases, and apparently in these cases alone, can be accepted as sufficient evidence in support of a causal connexion.

NICOTINE AND TOBACCO.

At one time doubt was thrown upon the assumption that the characteristic effects of smoking were produced by the nicotine of the tobacco, but it seems now to be fairly well established that the nicotine is at any rate by far the most important constituent of tobacco smoke from the medical point of view, and it has, therefore, seemed worth while to analyse various smoking tobaccos, cigars, and cigarettes in common use in order to ascertain the percentage of nicotine in each. Speaking quite generally, it will be found that the judgement of a smoker as to whether the tobacco, cigar, or cigarette was mild or strong agrees very closely with the results of analysis; the agreement in the case of pipe-tobacco is, in fact, absolute. In the case of cigars, one called mild contained an appreciably larger proportion of nicotine than another, called strongest; but a third, also called mild, contained the smallest proportion of nicotine found in any tobacco examined except a German patent "non-nicotine" cigar, which contained little more than half the ordinary quantity in a mild Havana. The results of analyses of cigarettes are a little surprising, inasmuch as a Virginian of good quality proved to contain nearly twice as much nicotine as an Egyptian, and a common Virginian cigarette sold at five a penny, though it yielded less nicotine than a superior Virginian, contained a good deal more than either the Turkish or Egyptian cigarette. In comparing the effects of smoking pipes, cigars, and cigarettes, however, other factors besides the amount of nicotine present must be taken into consideration. When a pipe, cigar, or cigarette is first started, the smoke undergoes filtration in passing through the unburnt portion of the tobacco, and, in the case of a pipe, through the stem; as smoking proceeds, the percentage of nicotine in the shortening end of the cigar or cigarette must be much increased, and, when a holder is not used, this portion is in contact with the lips, and it is likely that some nicotine is absorbed directly in this way; whereas, with a pipe, filtration through the stem may, perhaps, become more efficient as smoking proceeds, as the smoke has to pass through a larger quantity of moisture; but it is not possible to say how far this advantage may be counterbalanced by the presence of an accumulation of nicotine from previous smoking of the same pipe. While habits, no doubt, vary as to the point at which a cigar or cigarette end is thrown away, it is probably

safe to assume that the end of a cigarette is usually a much larger proportion of the whole than is the end of a cigar, or of a pipe. The rate of smoking, too, is liable to vary, and it will probably be found that habitual and heavy smokers are considerably slower smokers than those who use tobacco less frequently. The weights of the cigars analysed varied from 60 to 100 grains; the five-a-penny cigarettes weighed 15 grains each, and the others about 21 grains each (without the paper); an average-sized briar pipe, filled with an ordinary smoking mixture, was found to hold about 75 grains. Observations on the time taken in the different forms of smoking showed that the same individual—a regular moderate smoker—took about fifty minutes for an average full-sized cigar, fifty minutes for a pipe, and twelve minutes for an ordinary cigarette. Taking the mild cigars, the mild tobacco, and the Egyptian cigarettes, and supposing four of the latter to be smoked in fifty minutes, the amounts of nicotine would be: Cigar, 0.9 grain; pipe, 1.1 grains; cigarettes, 0.9 grain. But, as already pointed out, it by no means follows that the amounts taken into the system would be in the same ratio as these numbers.

TUBERCULIN IN OCULAR DISEASE.

THERE can be now little doubt that certain ocular diseases present in so-called strumous individuals are often tuberculous in origin; among them may be included many cases of phlyctenular conjunctivitis, scleritis, and chronic irido-cyclitis. Many patients who present the typical ocular picture of interstitial keratitis associated with uveitis, but have not the other stigmata of congenital syphilis, are, there is good reason to believe, suffering from a tuberculous affection of the eye. It is unnecessary to assume the presence of actual bacilli; they are not found in phlyctenulae, nor do phlyctenulae often set up tuberculosis if introduced into a guinea-pig; the presence of tuberculo-toxin in the blood is sufficient to give rise to the lesions in the eye. This is quite obvious, for phlyctenulae frequently appear when tuberculin is placed in the conjunctival sac of a susceptible individual. The effect of appropriate tuberculin treatment is often so very encouraging that no effort should be spared to arrive at a correct diagnosis. This can only be done by the expert use of tuberculin. Derby and Török¹ have given most explicit directions for the use of tuberculin, both as a diagnostic and therapeutic agent. The first author states also that his experiences with the skin reaction of von Pirquet have been highly satisfactory. The papers should be read by all who wish to realize fully how common tuberculous eye disease is, and how best to treat it. A very interesting account, illustrated by two beautiful coloured plates of tuberculosis of the fundus oculi, has been published by Kraus and Brückner in the same periodical. In the two cases described test injections of tuberculin caused marked alterations in the fundus picture and rendered the diagnosis certain.

TOO OLD AT FORTY-FIVE.

THE voluntary retirement of the public vaccinator a few months ago created a vacancy in the Hounslow district. In their advertisement for candidates to fill this post the guardians of the Brentford union inserted a clause fixing an age-limit of 45 years for applicants. This imposes a penalty for being in the prime of life and medical experience, for which we see no justification. A petition was addressed to the guardians by local practitioners, pointing out that the restriction would deprive nearly every medical man practising in the district, and asking the guardians to

¹ Archives of Ophthalmology, September, 1908.

reconsider their decision. It was urged that the stipulation was unusual and unjust. To this petition the guardians replied that they were unable to alter the terms of the advertisement. An effort was also made to obtain the opinion of the Local Government Board by means of a letter addressed to the Secretary. This elicited a mere official acknowledgement of the letter. The matter was regarded by the local practitioners as a grievance. Two applicants withdrew, but the third declined to support the action of the local profession, and was elected to the post. Where united action is called for, success can be achieved only by unselfish loyalty on the part of every practitioner. The promotion of the social side of the life of the Divisions of the British Medical Association is doing much in the direction of securing more of this spirit of loyalty. In this way the chief hindrance will be surmounted to the removal of hardships and the establishment of just and equitable terms and conditions of service. On the question of age, there can be no doubt that boards of guardians have to some extent taken fright owing to the adoption of the Superannuation Act for district medical officers. Where too much regard is given to this, to the exclusion of other and more important considerations, false economy may be secured and efficiency sacrificed. The fallacy of too old at 45, adopted by the Brentford guardians, is not capable of explanation on this score, as public vaccinators are not entitled to superannuation. It may be, however, that the guardians in this union anticipate an early change by the authorities in the direction of superannuation for public vaccinators, and are anxious to take timely measures to safeguard themselves against the liability that would be created by such a contingency.

LORD LISTER.

LORD LISTER completed his 82nd year on April 5th. Though recognition of the value of his work did not come quickly, his name now marks an epoch in the history of surgery of which it may truly be said that there is *nil simile aut secundum*. His collected papers and addresses will shortly be issued in two volumes by the Clarendon Press. The profession throughout the world will join in wishing increased length of days and happiness to the man who has been the means of saving more human lives than have been destroyed by all the conquerors that have been the scourge of mankind. There is, moreover, this vital difference between his work and theirs—that its beneficent action will continue, ever extending its area, as long as civilization lasts.

CENTENARY OF OLIVER WENDELL HOLMES.

THE hundredth anniversary of the birth of Oliver Wendell Holmes falls, like that of so many other famous men, this year. He was born on August 29th, 1809, but the Historical Society of Cambridge, Massachusetts, where he was born and where he lived during his early manhood, proposes to celebrate the event somewhat earlier. To this it will devote its regular spring meeting, which occurs on April 27th next. Dr. Charles W. Eliot, President of the University, will preside, and other speakers will be: Dr. Edward Waldo Emerson of Concord, son of Ralph Waldo Emerson, and an associate of Dr. Holmes in the famous Saturday Club; Colonel Thomas Wentworth Higginson, an intimate friend of Dr. Holmes; Dr. David Williams Cheever, who was his assistant when he was Professor of Anatomy in the Harvard Medical School; and the Rev. Samuel M. Crothers, D.D., of Cambridge, described by Mr. Frank Gaylord Cook, secretary of the society, as "one of our foremost humorists." Several selections will be sung by the Harvard Glee Club, and Mr. Charles Townsend

Copeland, instructor of elocution in the university, will read two poems by Dr. Holmes—namely, "The Last Leaf" and "The Chambered Nautilus." The celebration is in honour of Holmes in his poetical literary character; but the medical profession will not forget—that he himself never forgot—that he was one of our body. It may be that he was as proud of having written "The Chambered Nautilus" as he was of having called attention to the contagiousness of puerperal fever. Fine as much of his literary work is, however, we think that his most enduring title to fame is the service he did mankind by that famous essay.

BERLIN PROFESSORS AND RUSSIAN PATIENTS.

A FEW days ago the daily papers reported under "scare" headlines that a gross violation of medical ethics on the part of certain professors in Berlin had been brought to light in a libel action. Since the charges made have not yet been proved, and since these charges rest so far on the evidence of a few witnesses, we must content ourselves with briefly stating what has happened, deferring all discussion of the position until the investigation which is being made has brought the facts fully to light. It appears that a Dr. Levin accused Professor Moll of bribing certain persons to induce rich Russian patients to place themselves in his hands. The latter instituted a libel suit, and obtained a nominal verdict with 30s. damages, while the judge stated that evidence on oath had revealed that it was the practice of certain professors to pay money to third parties for bringing them patients. Among those implicated is Geheimmedizinal-rat Professor Senator, who is President of the Berlin Medical Society. On learning of the charges he at once resigned his presidency and demanded a full inquiry into the charges. Rumours have long been current in Berlin that some consultants have been guilty of the practice referred to, but the matter has now for the first time been sworn to in open court. We can only express the hope that men holding a prominent position like those whose names have been mentioned in the press, will have little difficulty in dispersing the cloud which threatens to burst over the consulting quarter of the capital of the German Empire.

MEMORIALS of great men are not always suitable, the worst, of all, we think, being the useless and too often inartistic statue. An instance of a peculiarly appropriate mode of commemorating a man who rendered service to his fellow men is the institution for surgical research which it is proposed to endow in memory of Dr. William T. Bull, of New York, an obituary notice of whom appeared in the JOURNAL of March 27th. The institution will be connected with the College of Physicians and Surgeons, Columbia University, where Dr. Bull took his degree in 1872, and where he was for many years professor of surgery. It is further stated that Mrs. Bull proposes to erect a memorial hospital for the treatment of tuberculosis.

THE National Association for the Prevention of Consumption has arranged to hold a tuberculosis exhibition at the Art Gallery, High Street, Whitechapel, in June. The exhibition will illustrate the extent, cause, spread, prevention, and cure of tuberculosis, and will have a special section devoted to tuberculosis in children. It is expected that the exhibition will be opened by the President of the Local Government Board on June 2nd, and it is proposed that after it has been shown in London it should be taken to various provincial cities and towns in England. Further particulars can be obtained on application to Dr. H. Hammond-Smith, 20, Hanover Square, London, W.

Medical Notes in Parliament.

The Housing and Town Planning Bill came on for second reading on Monday, and gave rise to a very interesting debate.

Mr. Burns, in moving the second reading, gave a short history of the fortunes of the Bill last year, and said it had now been introduced according to the pledge of the Government in the shape in which it had passed the Standing Committee last session. The points raised on the notice paper did not touch the principle of the Bill, and as regards commons and open spaces there was no desire to attack or filch them for the purpose of erecting working men's dwellings. The Bill made Part 3 of the Act of 1890 compulsory instead of adoptive, and gave increased facilities for acquiring land for housing the working classes. It strengthened the law for closing orders, and threw upon the landlord the responsibility of keeping the house reasonably fit for living in. It dealt with town planning in a liberal and comprehensive spirit, and in the third portion of the measure medical officers of health were dealt with. There were sixty-two county councils in England and Wales, and up to recently only half of them had medical officers. He did not think that this country, which, for the last hundred years, had led the world in public sanitation, should remain longer under the reproach of not having in every county of England and Wales a whole-time medical officer. And they had decided that every county council should have a whole-time medical officer, devoting all his abilities and services to public health and sanitation. Bearing in mind the special provisions of this bill, this in itself, especially when the terms and conditions under which the medical officer serves are to be approved by the Local Government Board, should give some satisfaction to the members of a useful and honourable profession, which has a right to be protected against, at times, the capricious local interference which prevents them from doing their duty to the body politic as well as they otherwise ought to be allowed to do it. After referring to the abolition of cellar dwellings, he spoke of back-to-back houses, and said where they prevailed we had this remarkable result: Whereas the average age at death of the gentlemen and the professional classes was 44, amongst the tradesmen it was 27, and amongst operative labourers and their families it was 19; that is, 44 as against 19. His medical advisers advised him that the back-to-back houses were responsible in the day of this report for a death-rate of 431 per 1,000 over the town as a whole, and an infant mortality of 570 per 1,000 of children under 5 years of age. It was represented to him, on the responsibility of Dr. Tatham, Dr. Niven, and Dr. Sykes, and other well-known medical men, that where all causes were responsible for 27 per 1,000 of deaths, it was 38, and not 27, in back-to-back houses; infectious diseases were 4.5 in through-ventilated houses and 8.7 in back-to-back houses; consumption stood at 2.8 in through-ventilated houses and 5.2 in back-to-back houses. In the ordinary houses occupied by the labouring classes in regard to lung complaints the percentage was 6.6 in through-ventilated houses and 9.2 in back-to-back houses. Where the children die from diarrhoea it was 1.4 in through-ventilated houses and 3.4 in back-to-back houses. In a town that had recently expressed its desire to be allowed to continue these back-to-back houses, he found this very suggestive comment made by one of the best authorities on housing (Mr. Dewsnap) in one of the best books on the subject recently written. He said, speaking of Leeds back-to-back houses:

Newly built houses may look attractive, but what will be their condition after years of wear and tear? More than a probability that the conclusion of Manchester will be justified.

England was not so destitute of land upon which to house its poor that they should be housed in working-class tenements without a back yard in which to chop the wood and put the coal, and in which the children could play whilst the mother was able to keep a friendly eye on them through the washhouse window, and at the same time continue to carry on her domestic duties. All this was impossible in back-to-back houses, where the children had only got a stuffy room for a playground; and in the days of rapid

traction they had no right to relegate children to play in a small front garden, or in the road or street, when the community was rich enough to provide the humblest garden in the majority of cases, and some measure of a back yard in which the youngsters could play whilst the domestic duties in the house were being carried out. This could be done better in through-ventilated houses with a back yard and a garden than was possible in the case of back-to-back houses.

Mr. Lyttelton followed in support of the second reading of the bill, which he criticized in a friendly spirit. He especially objected to the clause which provides for a quinquennial census of all houses as expensive and unnecessary. He doubted the fairness of the bill as regards compensation to landowners for land to be taken for housing purposes, and he concluded by pointing out with much force that if the bill was to be properly worked a large additional staff would be necessary at the Local Government Board.

Sir Walter Foster followed, and strongly supported the suggestion that the bill would require the Local Government Board to be largely reinforced, so that the work of inspection in the counties could be efficiently carried out. He could not, however, agree with the opposition to the quinquennial census of houses in all districts. He had some small share in inserting the clause in the bill, and he regarded it as a most valuable provision for educating public opinion by a publication of the facts concerning every district. It was true that powers of inspection existed in another clause; but hitherto such powers had been very imperfectly carried out, and there was a vast difference between a simple inspection and a published record accessible to every one of the results of the inspection of every house. It would not only educate the locality but would be invaluable to the county council if that body had to interfere in case of local default. As regards the powers of forcing small local authorities to do their duty, he had great confidence in the county councils; he believed they would supervise their whole areas and stimulate district councils to take up this work. As regards the powers resting ultimately with the Local Government Board, he had less faith in the mandamus than many people. It generally proved a feeble weapon, but inspection from the central authority would do much good. One of the best things in the bill was the compulsory appointment of a medical officer of health for every county. With reference to housing, the very root of all power to act was in the interests of public health. It was the only logical basis for interference with private property. Bad housing increased the death-rate, and the county medical officer would be always anxious to improve this in order that record of his work might appear good. Under the bill medical experts, assisted by sanitary inspectors, would look after not only the rural, but the neglected urban parts of the county, and in time search out and improve every black spot. These county medical officers could do their work fearlessly, for they were given a position of security which every health officer ought to have. The bill provided that they were not to be dismissed except with the consent of the Local Government Board. One of the great difficulties in this country on this question had been the system of allowing medical officers of health for small areas to receive £10, £20, or £30 a year, and be appointed annually by small local authorities. They had heavy work to do, and if these men could be given a security of tenure much good would result. Take a case in point—a small town, say, of 10,000 inhabitants. It had an urban district council. A medical officer of health was appointed at a salary of £25 or £30 a year. He did what he could to improve the sanitary condition of the district, but at the end of twelve months he was dropped. Why? Because he had been a little too zealous. He knew, and the President of the Local Government Board knew, cases in which men, after twelve months' active service in connexion with the housing of the people, were not reappointed by the district councils, and were dropped because they did their best to bring about a better state of things in the poorer districts. That was a scandal which ought to be removed. It could be removed if the Local Government Board would give the right of appeal on the part of these medical officers to itself. Even in watering places of 15,000 or 20,000 inhabitants men were dismissed

for being too active in looking after the public health. These men should be made independent in their very difficult and serious duties, so that they might look thoroughly after the habitations of the poor.

The debate was continued by Mr. Lane Fox, who moved an amendment (afterwards rejected) to prevent the cost of housing falling on local rates, as it should be a national burden. Mr. Hicks Beach, Sir J. Dickinson Poynder, and others spoke, and finally, after a conciliatory reply from Mr. Masterman, the bill was read a second time, and referred to a Committee of the whole House.

Public Health Acts (Consolidation).—In answer to Mr. Rees, the President of the Local Government Board said last week that he appreciated the advantages there would be in consolidating the Public Health Acts, though it would probably be found necessary in the first instance to amend them in some respects. He should be glad to take steps in the direction indicated when opportunity offered, but he did not think it would be practicable to deal with the matter during the present session.

The Local Government (Scotland) Bill has been again introduced by Mr. Cathcart Wason. It proposes to protect outdoor medical officers in Scotland from arbitrary dismissal by parish councils by giving them the same position as their English and Irish brethren in a right of appeal to the Local Government Board. The bill is influentially backed on both sides of the House.

The Asylum Officers' Superannuation Bill.—Late on Thursday night last week this bill passed its second reading without discussion, and on the motion of Sir William Collins was referred to a Select Committee. Its prospects will now depend on how it fares before the Select Committee, which will probably also have the Scottish bill for the same object before it, but it is quite possible both bills may pass this session.

The Oaths Bill has passed through the Standing Committee, and now has every prospect of becoming law. It has been strengthened in Committee, and every oath is to be administered as prescribed by the bill in the Schedule, which reads as follows:

The officer administering the oath shall address the person taking the oath in the following form: "You swear by Almighty God that," and then proceed with the words of the oath prescribed by law, omitting any further words of imprecation or calling to witness; and the person taking the oath shall, with uplifted hand, say "I do."

If the oath is an oath which is customarily taken by the words of the oath being read or repeated after the officer administering it, the words shall be read or repeated with uplifted hand in the form following: "I do swear by Almighty God that," and then proceed with the words of the oath prescribed by law, omitting any further words of imprecation or calling to witness.

New Bills.—Several new bills have been recently introduced which are of medical interest. First may be mentioned Mr. Dickinson's Metropolitan Sewers and Drains Bill, which seeks to amend the law relating to combined drainage. There are two kinds of combined drain—the "combined drain" which in law is a "drain," and the "combined drain" which in law is a "sewer." The former is repairable by the private owner, the latter by the public authority. The consequence has been great confusion in the interpretation of the law, and this bill seeks to remove it, and give the metropolitan local authorities the same powers that have already been given to several provincial authorities. The Registration of Nurses (Scotland) Bill, introduced by Mr. Cleland, seeks to establish and make regulations to provide a register for nurses in Scotland. It is drawn on the same lines as the bill of Mr. Munro Ferguson for England. Sir John Jardine has introduced a bill to provide for the grant of superannuation allowances to officers and servants of public and district asylums in Scotland. Lord Robert Cecil keeps up his interest in infant life protection, and has presented a bill to prevent the destruction of children during birth. The Local Education Authorities (Medical Treatment) Bill, introduced by Mr. Walter Guinness, proposes to provide for the recovery by local education authorities of costs for medical treatment of children attending public elementary schools in England and Wales. In the Lords the Bishop of Hereford has

introduced a Bill to prevent Cruelty to Animals. It has nothing to do with vivisection, but seeks to make it an offence to hunt, shoot, or course an animal which has been kept in confinement and is released for such spurious sport.

Escapes from Asylums.—Mr. Chiozza Money asked the Home Secretary how many imbeciles and lunatics had escaped from public asylums in the United Kingdom since January 1st, 1909. Mr. Gladstone said that the Commissioners in Lunacy informed him that there had been 67 escapes from asylums in England and Wales this year. He was not in possession of the figures for Scotland and Ireland. In reply to a further question he answered that a report from the Commissioners in Lunacy of an inquiry which, at his request, they had made into the escapes of lunatics from the asylums in the neighbourhood of Epsom, and matters connected with the supervision of patients both within and beyond the asylum boundaries, had been recently presented to Parliament; it gave also the views of the Commissioners, with which he concurred, on the general question of exercising patients outside asylum boundaries.

Vaccination (Exemption Certificates).—In reply to Mr. Armitage, the President of the Local Government Board stated last week that the total number of certificates of conscientious objection received by the vaccination officers in 1907 was 57,671. The returns for 1908 were not quite complete, but the total number of certificates and statutory declarations with respect to conscientious objection received by the vaccination officers during that year might be stated approximately as 163,000.

Deaths from Burns and Overlying.—In answer to Mr. Alfred King, the Home Secretary stated last week that a supplementary table giving the number of inquests held in cases where death was caused by burns and scalds was inserted in the Criminal Statistics for 1904. In that year, according to this table, the deaths from burns at unprotected grates and stoves numbered 988, while the deaths from scalds at unprotected grates and stoves numbered 134. These were distributed between the County of London and the rest of England and Wales, as follows:

	Burns. Scalds.	
County and City of London ...	104	20
Elsewhere in England and Wales ...	884	114
Total ...	988	134

The great majority were children, but the exact numbers could not be given. No later figures had been collected. The following were the deaths of infants caused by overlying in the last three years for which figures were available:

	1905.	1906.	1907.
County and City of London ...	405	335	344
Remainder of England and Wales ...	1,060	1,118	1,129
Total ...	1,465	1,453	1,473

The 1908 figures were not yet ready.

Uncertificated Deaths in the Highlands.—Last week, in answer to Mr. Weir, the Lord Advocate stated that the number of uncertificated deaths in the Highland crofting counties was as follows:

County.	1903.	1904.	1905.	1906.	1907.
Shetland ...	156	136	123	86	100
Orkney ...	52	55	39	49	46
Caithness ...	45	41	41	34	44
Sutherland ...	92	72	90	81	98
Ross and Cromarty ...	327	298	304	233	307
Inverness ...	337	279	258	251	261
Argyll ...	137	99	82	93	100

Easter Holidays.—The House of Commons on rising on Wednesday adjourned till Monday, April 19th.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

WOMEN STUDENTS AT ST. ANDREWS.

A significant fact in connexion with the graduation ceremony at St. Andrews University on March 31st was the number of women students who received the degree of Master of Arts—out of 50 graduates 38 were women. In connexion with this matter, at a meeting of the general council of the university held on April 1st, a communication was received from the Students' Representative Council regarding the relative number of men and women students. It was pointed out that whereas the number of women students was rapidly increasing in the four universities of Scotland, and without as yet any indication of slackening in the rate, the number of men students, while also growing, was growing very slowly. This great increase in the number of women students was confined almost entirely to the Arts Faculties in the universities, in which they now formed 46 per cent. of the total number of students. These facts had peculiar significance to St. Andrews University, not only because its strength was in its Arts Faculty, but also because the proportion of women students in that faculty was much higher than in the Arts Faculties of any of the other three universities, forming 61 per cent. of the whole. The report proceeded to point out that this extremely high percentage of women was a possible source of danger in the near future to St. Andrews University, and it was therefore advisable to avoid that danger by keeping the percentage of men students as far as possible above that of women. The report recommended that St. Andrews University might, as a corrective, turn its attention to the development of its science and medical schools, and also encourage the department of military subjects.

GRANTS TO SCOTTISH UNIVERSITIES.

The Treasury has appointed a committee to consider the statement of claims to additional State assistance submitted by the Scottish universities, and to report what assistance, if any, should be granted from public funds in the interests of the development of the work of the universities, with due regard to the co-ordination of their work with that of other institutions in Scotland giving instruction of a university standard. The committee is composed as follows: The Right Honourable the Earl of Elgin and Kincardine, K.G. (Chairman); Miss Haldane; Sir Kenelm Digby, G.C.B., K.C.; Principal Sir Harry Reichel, LL.D.; Mr. Charles Mackinnon Douglas; Professor Andrew Russell Forsyth, Sc.D., F.R.S.; and Professor G. Sims Woodhead, M.D. Mr. Hubert Warre Cornish will act as secretary to the committee.

THE GLASGOW ROYAL INFIRMARY SCHEME.

For some time there has been little news about the course of the negotiations to found new university chairs at the Royal Infirmary. Last week some remarks made by the President of the St. Mungo's College at the half-yearly meeting indicated that considerable progress has been made. He was able to state that the negotiations between the college and the university were so far completed that the governors of St. Mungo's College had been able to instruct their Parliamentary solicitors to proceed with a draft provisional order which will, in due time, be submitted along with similar orders from the university, and it is believed, also from the Muirhead trustees. The university authorities do not seem to be quite so far advanced as the St. Mungo governors, but it is understood that there is now little doubt that the proposed scheme for instituting chairs at the Royal Infirmary will eventually be adopted after it has been in turn submitted to the discussion of the Medical Faculty, and then to the Senate. Owing to the prospect of a new Chair of Pathology being instituted in the Royal Infirmary, more than ordinary interest is attached to the filling up of the vacant post of pathologist. It is understood that the infirmary directors will reserve to themselves the power of revising the appointment on the institution of the new chair. As some of the strongest likely candidates for the chair are applying for the present vacancy of pathologist, it is

felt that the successful candidate will stand a very good chance of eventually becoming the new professor.

GLASGOW WESTERN INFIRMARY.

Last week the managers of the Western Infirmary appointed Dr. J. Carslaw and Dr. J. S. McKendrick assistant physicians to the hospital. In connexion with these appointments an innovation was made, as these appointments are for ten years. In this way promotion will be accelerated.

NOTIFICATION OF BIRTHS IN GLASGOW.

In a report to the Health Committee of Glasgow Corporation Dr. A. K. Chalmers makes some interesting points. During 1908, out of 23,733 births, 86.3 per cent. were notified. The smallest proportion of notifications was in the Kelvinside Ward (63.3 per cent.), while in Cowcaddens Ward the maximum ratio of 99.3 per cent. was obtained. In eight other wards the percentage of notifications was also over 90 per cent. of the births; in five wards it was between 80 and 90, and only in two wards below 70. Of the 20,485 births notified, 45 per cent. were attended by medical men, while 55 per cent. were attended by midwives or handy women. The lowest proportion (24.3 per cent.) of medically attended births was found in the Cowcaddens Ward, and in two other wards the proportion was below 30 per cent. Using the notifications, it was for the first time possible to compare on a fairly reliable basis the incidence of puerperal fever in medically and non-medically attended cases. Of the 117 cases recorded, 32 had been attended by medical men and 85 by midwives, corresponding to a rate of 3.4 per 1,000 births attended medically, and 7.5 per 1,000 of those births attended otherwise.

MEDICAL EXAMINATION OF SCHOOL CHILDREN.

The Scottish Education Department has issued a memorandum, with a covering letter, on the subject of the medical examination and supervision of school children. The memorandum draws the attention of school boards to the principal provisions of the Education (Scotland) Act, 1908, as regards medical inspection of children, and urges them to proceed at once to the elaboration of a scheme that shall be as near as possible uniform. The department regard it as fundamental that the proposals should provide for the appointment of a single responsible inspecting officer, presumably a holder of the Diploma of Public Health, who should not be a private practitioner, and who should be furnished with as much assistance as may be necessary to enable him to perform his duties satisfactorily. Judging from the experience of England, it is obvious that in ordinary circumstances the assistants of the school medical officer ought to be, like himself, specialists, expressly debarred from engaging in private practice. Apart from other considerations, it is easy to foresee that complications may arise, in the event, almost inevitable in a populous district, of one medical practitioner being called on to examine his brother practitioner's patients. The whole-time medical inspector would be only necessary in the large towns, such as Edinburgh, Glasgow, Dundee, Aberdeen, and Leith. Elsewhere the ideal just described must be kept no less steadily in view, and a system of grouping adopted. Normally each county, along with the towns and villages not otherwise provided for, will be regarded as a single area, to be placed under the charge of a single responsible officer, who will be assisted to such an extent as may prove to be necessary. In some rural parishes it may conceivably be found practicable in the absence of conflicting interests to utilize the services of the local practitioner as assistant. There are districts in which the employment of nurses will be almost indispensable to success, and it should be understood that their employment generally is favoured by the department, although it does not for the present seem necessary to stipulate that they shall form an integral part of the scheme in all cases. The department considers that in certain parts of Scotland, notably in the Highlands, the scattered character of the population and the difficulty of communication may render it difficult to institute in the immediate future a comprehensive system of medical inspection, and in certain cases, a committee may deem it prudent to refrain from formulating a scheme until it can draw upon the experience of committees dealing with populous districts.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

AN INTERESTING APPOINTMENT.

HIS EXCELLENCY THE LORD LIEUTENANT has appointed Miss M. A. MacDonnell, R.R.C., to be a member of the Board of Superintendence of Dublin Hospitals. The function of this body, under Act of Parliament, is to inspect and report upon the various hospitals which receive aid from the parliamentary grant. Miss MacDonnell has just resigned her position as Lady Superintendent of the Richmond Hospital after twenty-one years' service, and has received from the sisters and nurses an illuminated address and a handsome gift. She served in the South African war as matron of the Irish Hospital—500 beds—and received from the King the Order of the Royal Red Cross. She is the first lady member of the Board of Superintendence, and the appointment will be universally approved, not only on personal grounds, but because of the precedent established.

PROPOSED ENLARGEMENT OF BELFAST OPHTHALMIC HOSPITAL.

The annual meeting of this hospital was held at the institution on March 29th. Dr. Cecil Shaw, honorary secretary to the surgical staff, read the medical report for the year, which showed a large amount of operative and general work, and increasing popularity of the institution. The surgical staff again pressed for the comparatively modest sum of £500 to bring the theatre and wards up to date. Dr. J. Walton Browne, senior surgeon, said they could not refuse admission to some urgent cases without jeopardizing the eyesight and hearing of the applicants. He had himself raised about £100 of the sum required, so deeply impressed was he with the gravity of further delay. An apology was received from Earl Shaftesbury, the president, for his unavoidable absence, and he also expressed his sympathy with the movement.

SALARIES OF BELFAST CORPORATION OFFICIALS.

On the resignation of Sir Samuel Black, the ex-Town Clerk and Solicitor to the Corporation, a retiring allowance of £2,000 a year was granted. The post has now been divided and a new Town Clerk (Mr. Meyer), at £1,000 a year, has been appointed, and the post of Town Solicitor, also at £1,000 a year, created. Large as these sums may appear, few, if any, will grudge Sir Samuel Black his well-earned pension, or Mr. Meyer, one of the most popular and able of officials, his well-earned promotion. The humour of the situation is that a few years ago the City Council refused to allow the new medical officer of health a higher salary than £600 a year, although most citizens and an association whose duty is to promote civic economy, advocated £800 to attract first-class applicants for the post.

THE WOMEN'S NATIONAL HEALTH ASSOCIATION OF IRELAND.

Her Excellency the Countess of Aberdeen inaugurated yet another branch of this popular and energetic Association on March 24th, at Tandragee, co. Armagh. There was a large attendance, and Sir John Byers, M.D., in moving a resolution in support of the Association, gave an admirable address on tuberculosis from the point of view of the farmer. Dr. Taylor, of Tandragee, cordially supported the formation of the branch.

England and Wales.

MANCHESTER AND DISTRICT.

LIMITATION IN MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE announcement that the Board of Education has sanctioned a scheme for London under which only abnormal children will as a general rule be medically examined will doubtlessly lead to application for similar sanction in Lancashire. Several medical officers of health in Lancashire have freely expressed the opinion that it

would be a waste of public money to insist on a full examination of all children in elementary schools, and as a matter of fact only a few authorities are attempting it. The statement that in London it would cost 5s. a child for full inspection of every case, and that the cost would be reduced to only a few pence a head on an all-round calculation if only abnormal cases are examined, will go far in the overrated Lancashire towns to restrict the scope of examination. The question, however, arises, How will the children for examination be chosen? Will only those with perfectly obvious defects be picked out for fuller examination? If so, many cases which really need medical attention will be overlooked. Or will the teachers be expected to make a preliminary examination and to pick out those needing full medical examination? Opinion as to the advisability of imposing such duties on the teachers is nearly equally divided in the Manchester and Salford Divisions of the British Medical Association. On the one hand, it is said that a short course of instruction to teachers in the early symptoms of the common diseases of childhood would be useful in many ways. With this knowledge they would often be able to detect defectives and put them aside for examination by the medical inspector, and would save the time of the inspector and the consequent cost to the rates. On the other hand, it is argued that to add to the already onerous duties of teachers is inadvisable, and that it is not fair to put on them the responsibility of detecting diseases which if not attended to in an early stage may be more serious. It is evident, too, that there is a similar difference of opinion among the education authorities. In some of the schools near Manchester the teachers are supplied with Snellen's test cards, and are instructed how to make rough tests for myopia and hypermetropia. In other schools they do nothing but point out those suffering from ringworm, scabies, or pediculosis. What is generally being done is that the teachers point out the obvious cases needing attention, and the inspector gives a rapid glance round the classes, and picks out a few children for further examination. This is useful as far as it goes, but it cannot be said to be an ideal system of medical inspection.

TREATMENT OF CONSUMPTION IN MANCHESTER.

Some idea can be formed as to the extent to which consumption prevails in Manchester from the report presented at the annual meeting of the supporters of the Manchester Hospital for Consumption and Diseases of the Throat and Chest. The meeting was held in the Lord Mayor's parlour, Manchester, and was presided over by Mr. W. J. Crossley, M.P. The Chairman pointed out that in connexion with the out-patient department in Hardman Street, Manchester, the institution possessed a hospital at Bowdon with 50 beds and the Crossley Sanatorium at Delamere with 90 beds. Both these hospitals had been continuously filled during the whole year, and he did not know how the expenses could have been met if the plan of having private patients had not been adopted. From this class last year £3,905 was received. He had recently visited Delamere, and, though it was at a great altitude, he found more than half the patients sitting out in the sunshine. Mr. C. Behrens, Honorary Secretary, said the system adopted at Delamere was the open-air method, together with a very liberal diet. The average stay of the patients was about three months; no doubt a longer time would be beneficial, but, owing to the demands for admission and the large number of patients always waiting, the board had been compelled to fix a limit of three months. The patients remained the whole day out of doors, except at meal times, and at night slept with their bedroom windows wide open. The 50 beds at Bowdon had been fully occupied during the year, and it is distressing to know that a considerable number of applicants are at all times waiting. All the patients here belong to the working classes, and an appeal was made for warm clothes, as many of the patients often went insufficiently clothed.

Dr. Moritz presented the report of the out-patient department. The total number of cases during the last year was 11,443, as compared with 11,163 in 1907. The attendances were 35,243, which was far in excess of any previous record. A large number of cases are sent in a stage too advanced to permit of their admission to the sanatorium or to warrant hope of any successful treat-

ment, and the Medical Board desire it to be made known that it is preferable to send doubtful cases for consultation, and even to admit to the sanatorium cases that are only suspicious, rather than wait till the disease is too extensive to allow of any hope of recovery. During the year the need of some in-patient accommodation in closer connexion with the out-patient department in Manchester for urgent throat cases and acute chest diseases has been greatly felt, as patients have come whose condition demanded immediate admission to hospital, not simply for relief, but in some instances even to save life.

The financial position of the hospital is a source of anxiety, since if it had not been for an anonymous donation of £1,000 there would have been a large deficiency on the year. The total income was £13,704, and the expenditure £13,516, and the year closed with a balance due to the bank of £782. Further, no additions have been made to the endowment fund of the Crossley Sanatorium, and £34,000 is yet wanted to make up the £100,000 needed to put it in a sound financial position.

WESTMORLAND.

MEATHOP CONSUMPTION SANATORIUM.

The ninth annual report of the Westmorland Consumption Sanatorium (January, 1909) shows that the institution continues to flourish, and that improvements have been carried out which will add still further to its efficiency. A wing has been added to the main building, providing improved accommodation for the domestic staff; the patients' dining-room has been enlarged, and four new chalets have been erected, bringing the total accommodation for patients up to 52 beds. Electric lighting has been installed; a disinfecter for clothing and bedding, and an apparatus for sterilizing and cleansing the patients' sputum cups, have also been provided. Plans have been prepared for dealing with the sewage effluent of the sanatorium on a bacterial system of septic tanks and filtration beds. It is evident that nothing is overlooked which is required to make the Meathop Sanatorium thoroughly efficient.

It is proposed to establish a home for advanced consumptives in connexion with the sanatorium, and a considerable proportion of the required sum for this has already been raised.

The medical report shows that 147 patients were admitted during the year, the average number in residence throughout the year being 42.59. Although the proportion of severe and advanced cases admitted is very greatly in excess of what is desirable, the result of the year's work is encouraging. A table showing the family history, as regards consumption, of the patients admitted supports the view that heredity is of no more importance in tuberculosis than in any other bacterial disease, such as measles, pneumonia, typhoid, or influenza, and emphasizes the importance of endeavouring to improve environment in the home, etc., as a preventive measure. A very interesting table shows the subsequent history of all the patients who have left the sanatorium since 1900 and who can be traced.

BIRMINGHAM.

HOSPITAL SATURDAY FUND.

The annual report of the Executive Committee stated that the thirty-sixth annual collection amounted to £20,632, which was made up as follows:—Collections in manufactories and industrial establishments, £20,516; interest allowed by bankers, £116. This total is the highest yet obtained in the history of the fund, and is £523 in excess of the previous year's collection. The firms subscribing numbered 2,153 as against 2,149 in 1907. The number of patients treated at the various convalescent homes supported by the Hospital Saturday Fund were as follows:—At Tyn-y-Coed, Llanrhos, near Llandudno, the convalescent home for men, 1,199 patients were admitted during 1908 as compared with 1,088 in 1907; at Marle Hall, Llanrhos, the women's convalescent home, the number of patients was 1,209, against 1,188 in 1907; at Red House, Great Baar, the convalescent home for children, 566 children and 98 women were admitted, as compared with 400 children and 94 women in 1907. The total number of patients in 1908 was 3,072, as against 2,809 in 1907. The

committee has also assisted the Crippled Children's Union by sending during the year to the Red House 59 of that society's children, free of cost. Since the establishment of the fund in 1873 £400,000 have been collected, and the expenses have been under £20,000, or under 5 per cent. for the whole period.

WEST YORKSHIRE.

THE BRADFORD MEDICO-CHIRURGICAL SOCIETY.

A SPECIAL general meeting of this Society was held at the Midland Hotel, Bradford, on March 31st, when Mr. H. Percy Dean, surgeon to the London Hospital, gave an address on Spinal Anaesthesia, with special reference to Abdominal Conditions. On account of the prevalence of influenza in Bradford and the absorption of the medical men in their work the attendance was unfortunately not as large as it would otherwise have been. Mr. Dean's address was of the greatest interest, and was followed by a discussion in which many of those present joined. At the annual dinner of the society, which took place the same evening, between forty and fifty members and guests were present. Some excellent speeches were made and some songs and recitations given by members.

South Australia.

RHODES SCHOLARS.

THE Committee of Selection for the Rhodes Scholarship, which is annually allotted to South Australia, has for the second year in succession chosen a medical graduate. Last year, William Ray, M.B., B.S. Adelaide, went to Oxford, and the Regius Professor (Dr. Osler) speaks of him as a most promising student. This year, Henry Kenneth Fry, B.Sc., M.B., B.S., will join him there, having, like Ray, carried off every possible prize during his undergraduate career.

THE SOUTH AUSTRALIAN BRANCH.

The Branch flourishes, even if it does not increase very rapidly in numbers. The annual meeting in June was a great success, and Dr. J. H. Evans, in his valedictory address, dealt with the important subject of "school hygiene" in a very able and interesting manner. In the absence of Dr. A. M. Morgan, the newly elected Vice-President, Dr. W. A. Verco took the chair at the annual dinner which followed; this is the first occasion on which these posts have been filled by graduates of the University of Adelaide. An arrangement has been made with the council of the university, whereby a room will be placed at the disposal of the members of the Branch, and a medical library maintained, the Branch guaranteeing a subsidy of £50 for ten years. To meet this liability, the subscription of members residing within twelve miles of the metropolis has been raised from two guineas to £3 a year, whilst country members will have certain privileges if they care to increase their subscription to £2 10s. a year.

THE HOSPITALS.

Dr. Anstey Giles has resigned, and Dr. C. E. Todd succeeds him as full surgeon to the Adelaide Hospital, Dr. Newland taking the junior position. Dr. R. S. Rogers has also resigned, and has been appointed a consulting physician to the same institution. Having come in recently for a windfall of something like £80,000, the hospital is spending a very considerable amount on a nurses' home, about £30,000 it is said; and though the grounds are quite spacious, the home is being built just where it will prevent any expansion of the out-patient department, which may be necessary in the future; such luxuries as costly marble baths, which few of us can afford in our own homes, are mentioned amongst the conveniences with which it is to be replete. At the Children's Hospital, Dr. Newland has been promoted to be surgeon to in-patients, vice Dr. Morgan resigned; and Dr. Harold Evans, a former resident medical officer, becomes Surgeon to the out-patient department. Dr. Morgan, who spent some months in England last year, is now devoting himself to ophthalmology, and is acting as locumtenent for Dr. Symons at the Children's Hospital.

India.

[FROM A CORRESPONDENT.]

ASSOCIATION OF MEDICAL WOMEN IN INDIA.

A NUMBER of medical women were present at the Bombay Medical Congress, the committee having very considerably reserved front seats for them in the Lecture Hall. The first general meeting of the Association of Medical Women in India was held on February 24th, at the house of Dr. Annette Benson, Physician in Charge of the Cama Hospital. Forty-two members were present, representing medical aid given to women and children in Government, mission, Dufferin, and native State hospitals. Miss Benson, M.D. (President of the Association) took the chair, and opened the proceedings in the following speech:

I offer all present a hearty welcome. With this meeting we inaugurate the Association of Medical Women in India, and it is with the greatest pleasure that I see such a large gathering of the association which only began to be organized two years ago. In few words I will describe the first object which we have before us to-day. Looking at the medical profession in India, we see men organized in a service offering worthy careers to its members, with fair rules of pay, promotion, leave, and pension. We see women a nondescript, scattered number of isolated units, at the mercy of chance employment and still more chance conditions of service, and almost all in subordinate positions. Yet the majority of better-class women of India have no one to look to for help in sickness and childbirth but these same isolated units. For the good of this large factor of the population, and therefore in the name of the public weal, we aim so to improve the conditions under which medical women work as to make their work efficient and their reward fair. When you have amended and confirmed the constitution proposed last August, you shall have laid before you a scheme for the organization of medical women in India.

The constitution and rules with amendments were then read. Miss Staley, M.B., described on behalf of the council a scheme for the organization of a women's medical service for India. This scheme was referred to a subcommittee to report to the council.

Dr. Baumbler spoke on the improvement that had taken place in women's hospitals in the last twenty years. Dr. Brown on the training of dais, and Dr. O'Hara against the training of indigenous dais as now conducted. Letters from various members were read.

The President mentioned various members of the association who had done good work for it during the year—the honorary secretary, the editor, members of council, and the member who had conducted the information bureau so successfully during the past year.

LADY MINTO'S INDIAN NURSING ASSOCIATION.

This admirable institution, whose object is "to provide and maintain a regular service of fully trained and experienced nurses throughout Northern India and Burmah," has been in existence for two years, and the report for 1908 gives evidence of growing appreciation and increasing success. The organization consists of a central committee in Calcutta, whose president is the wife of the Viceroy and whose secretary is the Viceroy's surgeon, and nine provincial branches. The central committee selects, pays, distributes, and discharges nurses, and the provincial committees control the employment and upkeep of the nurses and collect subscriptions and fees. Subscribers pay according to salary, and are entitled to a first claim on the services of the nurses and at lower rates than non-subscribers. Firms and regiments are permitted to join the association on special terms. Three lady superintendents and forty-four nurses constitute the staff, and 338 cases were attended during the year, of which 103 were cases of enteric fever. The income of the year amounted to Rs. 107,267, of which Rs. 33,172 were fees earned by the nursing sisters. Rs. 43,650 were invested. There is a home committee which, under the title of the Up-Country and Punjab Nursing Association, used to carry out on a more limited scale the same purposes now subverted by Lady Minto's association. The report, which is written by Surgeon-Lieutenant-Colonel W. R. Crooke-Lawless, C.I.E., honorary secretary, and Mrs. E. Davies, chief lady superintendent, is illustrated by several excellent photographs of the homes.

PLAGUE IN CALCUTTA.

Dr. T. Frederick Pearce, who exercises control over the special plague establishment in addition to his duties as health officer of Calcutta, has submitted a report of the prevalence of plague in the city during the year ending June 30th, 1908. This includes a "quiescent" period, July–December, 1907, and an "active" period, January–June, 1908. During the former, 313 deaths were registered, and during the latter 1,495, giving a total for the year of 1,808. This is the smallest aggregate since 1898, the year in which plague was introduced into Calcutta. The epidemic of 1908 was therefore exceptionally mild; it developed more gradually and later, reached a climax earlier, and declined more slowly. It is remarkable that the proportion of bubonic cases is higher in the active than in the quiescent period: in 1908 it was not so high as usual, also the case-mortality was less. The number of inoculations performed was 1,979, and no attack of plague occurred among these; 122,069 rats were destroyed, at a cost of Rs.16,036. Observations made by Drs. Hossack and Crake, special plague officers, indicate that, as in Bombay, the "rat-flea season corresponds with the plague season"; but "the comparative absence of fleas in Calcutta houses, and the practically complete absence of fleas on man," are held to cast doubt on the rat flea being the chief or only agent of infection.

Correspondence.

HUNGER PAIN AND DUODENAL ULCER.

SIR,—Mr. Moynihan evidently remembers the old legal adage, "If you have a bad case abuse the plaintiff's attorney." Having ventured, in quite temperate language, to express the opinion that hunger pain does not always point to the existence of a duodenal ulcer, I find myself denounced by him as a person whose views are always "fundamentally inaccurate," who trusts in diagnosis to what he patronizingly terms "chemistry and make-believe," and who is totally unacquainted with that peculiar variety of pathology which he calls "the pathology of the living." I venture to think, however, that a little more argument and a little less abuse of one who ventures to differ from him on a scientific question might have impressed your readers more favourably with the strength of his case, for, after all, we are both merely trying to get at the true meaning of a symptom, although we approach its study from different points of view, and I am perfectly ready to be convinced by Mr. Moynihan if he can show me that I am wrong.

Perhaps some misapprehension would have been avoided if, in my first letter, I had defined what I mean by "hunger pain." Dr. Herschell, for example, evidently distinguishes between hunger pain and the "pain of hyperchlorhydria." Now, I wish to make it quite clear that I, at least, recognize no such distinction, for the pain of hyperchlorhydria corresponds accurately to Mr. Moynihan's definition of hunger pain, inasmuch as it "comes on when a patient should be beginning to feel hungry for his next meal." Granted this definition of the term, I think Dr. Herschell would agree with me that hunger pain does not necessarily imply the existence of an ulcer in the duodenum. I know that this does not affect Mr. Moynihan's position one whit, for he evidently does not believe in the existence of hyperchlorhydria as a separate disorder at all, but regards it as a figment of the imagination, a product of "chemistry and make-believe," and so long as he pooh-poohs all evidence except that obtained by operation I do not see how I can hope to convince him. This only I would say, that if hunger pain really be always associated with the presence of an ulcer in the duodenum, then (1) duodenal ulcer is one of the commonest causes of pain during digestion, (2) it is quickly and easily curable by medical treatment, and operation for it is usually unjustifiable (as Dr. Hertz very cogently points out), and (3) the scars of healed duodenal ulcers ought to be amongst the commonest phenomena of the post-mortem room. Ten years' experience in the London Hospital out-patient department fails to show me how these propositions can be denied.

¹ Vide his article in the JOURNAL for November 15th, 1907.

As regards the evidence afforded by operation I am, perhaps, not so ignorant as it pleases Mr. Moynihan to imagine, for I avail myself very freely of the help of my surgical colleagues in gastric cases, and often witness their operations. I have hitherto supposed, however, with Dr. Saundby, that it is by no means always easy to say for certain whether there is an ulcer present in the duodenum without opening into the latter, and in this belief I have been confirmed by the statements of my surgical friends. On this point, however, I freely admit that I speak with no authority, and am content to leave Mr. Moynihan and his surgery to *confères* to settle it amongst them.

One word more. Mr. Moynihan has been kind enough to point out in detail the defects in my equipment which make my opinions on this subject (in his estimation) not worth serious consideration. So perhaps he will forgive me if I suggest in my turn that what he lacks is the sense of proportion which only comes from an extensive acquaintance with dyspepsia in all its forms and in all degrees of severity such as can only be obtained in a large medical out-patient clinic. When he has extended his experience in this direction it will be time enough for him to dogmatize, for "not till then"—if I may borrow his own language—"is he qualified to pose as critic; not until then can he speak with full authority."—I am, etc.,

London, W., April 5th.

ROBERT HUTCHISON.

SIR.—The reply to the question which so strangely puzzles Dr. Saundby is quite simple. The proof that a duodenal ulcer is present is the seeing it. A duodenal ulcer which has caused attacks of "hunger pain" can be seen, and felt, and displayed. If there is any doubt whatever as to the presence of an ulcer, in my opinion it is certain that no ulcer exists; and no operation upon the duodenum or the stomach is then permissible. The cause of the symptoms must forthwith be sought elsewhere; and, as Mr. A. B. Mitchell says, the gall bladder demands a special scrutiny, for cholelithiasis is responsible for the closest mimicry of the symptoms of ulcer. I would ask Dr. Saundby not to believe in the existence of a duodenal ulcer that he cannot plainly see, and neither to urge nor to sanction the performance of gastro-enterostomy in the absence of an obvious demonstrable lesion. It is not true that "in a large proportion of cases the surgeon who performs gastro-enterostomy is not in a position to say whether there is a duodenal ulcer or not." The surgeon can and must know, in every case without exception, that an ulcer is present before he undertakes this operation. There is no such thing as an invisible or impalpable duodenal ulcer. The intangible duodenal ulcer is usually a gall bladder full of stones, or an inflamed or tuberculous appendix.

I regret to find myself in profound disagreement with the views of Dr. Hertz, to whom I am very grateful for the work he has done in other directions than this. He tells me that the symptoms of duodenal ulcer "can be instantaneously relieved and in time caused to disappear entirely." I agree. That is one of the characteristics of duodenal ulcer to which I have repeatedly called attention. But what of recurrence? The most authentic feature in cases of duodenal ulcer is the recurrence of the "attacks"; an attack can be "cured," the ulcer remains, to cause fresh attacks in the future. It is true that the out-patient treatment of any large hospital relieves the symptoms in such cases, and the patient ceases then to attend. Dr. Hertz concludes, therefore, that "duodenal ulcer is easily cured by medical treatment." The evidence does not justify the conclusion. The relief of an attack is confused with the cure of the disease. Many of the patients upon whom I operate tell me that they have been "cured" repeatedly; and one of them, a medical man, told me with a smile that he had been pronounced "cured" fifteen times. Medical treatment relieves an "attack" due to a chronic duodenal ulcer; nothing but surgical treatment can cure the patient.

Dr. Hertz quotes the well-known statistics laboriously collected from the *post-mortem* records of Guy's Hospital by Perry and Shaw. They are absolutely irrelevant. I cannot conceive that the frequency of the fatality of any disease is to be measured by the number of bodies in which evidence of it is detected in the *post-mortem* room. Does a patient not suffer during life from any disease unless at last he dies in hospital from it? In forty years at Guy's

Hospital only one case of obstruction of the common bile duct by a stone was seen on the *post-mortem* table; and during twenty-five years only 333 bodies were found to contain gall stones. Do these numbers bear any sort of proportion to the frequency of these diseases, or can any just inference be drawn therefrom as to their fatality? Perry and Shaw also say (p. 203) that in the years 1826-92 there were 7 cases of perforating ulcer of the duodenum on the *post-mortem* table at Guy's Hospital. Does that represent the frequency or the mortality of the condition? Mr. Mitchell of Belfast operated upon 12 cases in 1907-8¹ with 12 recoveries (a record creditable alike to him and to the medical men who so quickly recognized the nature and gravity of the cases). Is doubt cast upon Mr. Mitchell's record by the fact that in sixty-six years only 7 patients died in Guy's Hospital with a similar condition? Surely all that can be said is that there is no correspondence in this, as in so many other cases, between clinical and mortuary experience. It is really time for the fetish worship of *post-mortem* statistics to be suppressed. They have their value; that no one denies; but that value must be tested constantly in the light of increasing clinical knowledge. If we are for ever to fix idolatrous eyes upon the pages of these ancient inspection records, and to ignore the lesson which the living can daily teach us, we are smitten with the intellectual blindness, and we are returning to the methods, of the Middle Ages.

It is not surprising that with false premises the false deduction is drawn by Dr. Hertz that "in the vast majority of cases" operations upon duodenal ulcer are "unjustifiable" (was that word weighed, I wonder?). I am not concerned, however, to convict Dr. Hertz of logical error. He has expressed his desire to see the work we are doing, and his record as an original observer is so distinguished that I am content to leave him to form his own judgement upon the material he will here investigate. He will find that the patients who have been so often cured by medical treatment embrace gladly the opportunity of that relief from their repeated sufferings which operation confers. And he will, I hope, be satisfied, as others in the like doubt have been, that surgical treatment is not only justifiable but compulsory, if the patient is to be freed from his sufferings, and to be relieved of the danger to his life with which hæmorrhage and perforation threaten him.—I am, etc.,

Leeds, April 5th.

B. G. A. MOYNIHAN.

ARTERIAL BLOOD PRESSURE BEFORE AND AFTER MUSCULAR EXERTION.

SIR.—In reference to the figures published by Dr. Oliver Williamson on blood pressure after enforced exercise,² the following observations reported by myself and Mr. Martin Flack to the Physiological Society on January 23rd last may be of interest.

We made a number of observations on the pulse, blood pressure and respiration which show that oxygen inhalation by maintaining or restoring the vigour of the heart, increases the lasting power and lessens the after-fatigue of athletes. The fatigue which follows an athletic feat seems to be mainly cardiac in origin, and due to want of oxygen. Want of oxygen lessens the nervous resolution of the athlete and his muscular power.

The blood-pressure observations were taken on the radial artery with the new Leonard Hill sphygmometer. This sphygmometer allows readings to be taken quickly and accurately.

In administering oxygen we used a wide mouthpiece fitted with valves, and a soft nose clip. The oxygen (or air) fills a bag holding 3 cub. ft. Between the expiratory valve and the meter an anaesthetic rubber bag is placed to act as an elastic cushion and prevent the meter being overrun.

The tests were both on boxers and on students, who ran up and down stairs as fast as possible a given number of times with or without oxygen before and after each run. The boxers were given air or oxygen in the intervals of the fight. The subjects breathed from a bag through a Zuntz metre, and did not know whether air or oxygen was in the bag. Blood pressure, pulse frequency, respiratory frequency, and breathing volume were recorded. Results show that time of the run is lowered, pulse frequency

lowered, and blood pressure kept up by breathing oxygen; breathing volume and frequency are not definitely changed; being dependent apparently on the rate of work and the CO_2 production, but a feeling of relief is given by the oxygen. The subject breathes easily, and with his belly rather than his chest. The breathing of the exhausted runner or boxer is thoracic, and this changes to belly breathing on inhalation of oxygen. The respiratory pump is allowed to fill the heart, and the pulse becomes full.

The figures (which will be found in the *Journal of Physiology*, vol. xxxviii, Nos. 2 and 3, February 9th, 1909) show that blood pressures may rise much higher than Dr. Williamson found. In hot baths we have found pressures as low as 60 mm. Hg. So the range under these extreme conditions in a student may be from 60 to 220 mm. Hg.—I am, etc.,

HUMAN AND BOVINE TUBERCLE BACILLI.

SIR,—With great interest I read in your issue of October 10th, 1908, a paper by Mr. Nathan Raw, M.D. Durl., etc., on Human and Bovine Tuberculosis.

The author states that bacilli of the *Typus humanus* produce pulmonary tuberculosis, tuberculous laryngitis, secondary intestinal ulceration, whilst bacilli of *Typus bovinus* produce tuberculosis of (1) mesenteric glands, (2) peritoneum, (3) lymph glands, (4) bones and joints, (5) meninges, (6) lupus, (7) genito-urinary apparatus, (8) middle-ear and acute military tuberculosis.

Hereafter Mr. Raw says that pulmonary phthisis is caused by the bacilli of the *Typus humanus*, which do not attack the other viscera, and that practically all other tuberculous lesions are the result of infection, generally in infancy, through the digestive intestinal tract, by milk and other food products containing bovine bacilli.

These statements have much interested me. Since three years I am now working in Chungking, Western China, as Surgeon to the Imperial German Consulate of the Province of Szechuan, and may be allowed to state that the most prevalent disease here is tuberculosis of every description, attacking every tissue and every organ of the native people. If Mr. Raw's opinion be right, the cause of these most frequent tuberculous lesions of bones, joints, glands, etc., must be the bacillus *Typus bovinus*. The carriers of bovine bacilli must, however, I should think, for the most part be bovines, suffering from *Perlsucht*, which propagate the bacilli by their milk and flesh. But in this part of China cow's milk is very scarce, and certainly in no way a staple food of the people. The children are suckled by their mothers for two and even three years, besides taking other food. If the Chinese of the better classes drink milk at all, it is the imported condensed milk. Beef, which next to milk would be the chief propagator of the bovine bacillus, is also hardly eaten, as Mohammedans are not very numerous here, and the followers of other faiths prefer pork.

Surely under these circumstances infection by bacilli of the bovine type on a large scale is not very likely, and I must think that the occurrence of such very numerous tuberculous affections of bones, joints, glands, etc. in such a country is somewhat contradictory to Mr. Raw's statements.

As to the route and time of infection I agree with Mr. Raw. Only to me it seems hardly possible that the food is the only carrier of the infection, at least, here in Chungking. The Chinese are very careless in matters of cleanliness. They spit wherever they stand and go, in streets and houses (they spit even on the foreigner's carpets!). The little children crawl on the ground, soil the fingers and faces with dirt containing bacilli, and swallow the latter. Flies may also carry bacilli to foodstuffs; or the phthisic grandfather wipes his own bacilli-infected mouth with his hand and feeds with the same hand, which is never washed, his beloved grandchild. In this and a hundred other ways bacilli are conveyed to the mouth and reach the intestinal tract. As dust, owing to the constant dampness of the air, is conspicuous by its absence here, I may tender the opinion that phthisis pulmonum also is caused by bacilli introduced by the intestinal route.

I am sorry to say that by want of accommodations and outfit I have as yet been unable to ascertain the presence

of both types of bacilli or of only one or the other by inoculation in animals. Microscopically I have found only bacilli which I diagnosed as belonging to the *Typus humanus*.—I am, etc.,

Dr. ASSMY, Staff Surgeon, German Army,

Attached to the I.G. Consulate,
Chungking, West China.

PULMONARY TUBERCULOSIS IN CHILDREN.

SIR,—Deductions from figures and statistics are notoriously dangerous, and I think a little reflection will convince Dr. Hamilton Williams that she has fallen into a serious fallacy when she makes the alarming statement that, because nearly 30 per cent. of those who die in London hospitals for children have tuberculous lesions in their lungs, therefore 20 to 30 per cent. of living children have pulmonary tuberculosis. If it were true, the race would soon become extinct. It may be instructive to apply the same method of reasoning to another common disease—cancer. Of all women who reach middle life, one out of eight will probably die of cancer; therefore, of all women past middle life, one in eight is suffering from cancer, which, as Euclid would probably have said, is absurd. Yet cancer does not kill, as a rule, nearly so quickly as does pulmonary tuberculosis in children, so that there is more time for cases to accumulate. The fact is, of course, that these serious diseases soon bring about a fatal issue, and consequently no such accumulation of cases as Dr. Hamilton Williams assumes can possibly occur.

After all, we must start from the solid basis of pathological anatomy, and this confirms the general belief that the ordinary so-called chronic phthisis of adults is rarely met with in childhood. In 100 autopsies on tuberculous children I only found it in three instances, and two of these were girls of 11 and 12 respectively, in whom the conditions were approximating to those of adult life. In the vast majority of cases of pulmonary tuberculosis in early life the disease spreads rapidly and very irregularly through the lungs; it not uncommonly invades them from the bronchial glands, in its course and physical signs it frequently simulates bronchopneumonia, other organs become involved at an early period, and in a large proportion of cases life is brought to an abrupt termination by general tuberculosis or tuberculous meningitis.

The essential difference between Dr. Hamilton Williams and myself is that she assumes that pulmonary tuberculosis in childhood runs a similar course to that which it usually does in later life, so that children suffering from it may continue to go about for a more or less prolonged period, just as adults commonly do. On the other hand, both from clinical and pathological experience, I regard it as usually an acute or subacute disease, which soon incapacitates a child from attending school, and generally proves fatal in a very few months at most. I fully admit that even when the disease is active and advanced the physical signs in the chest may be most ambiguous, and I have frequently come away from the *post-mortem* room in a chastened spirit, after finding that lungs in which I had just suspected the existence of tuberculous disease were riddled with caseous masses. The difficulty is the greater because children generally die before cavities have formed large enough to give rise to recognizable cavernous signs.

I am sorry that the simple question I asked at the end of my last letter has not elicited a single reply. May I urge some one who regards tuberculous milk as a very common source of pulmonary tuberculosis to explain why it is that tubercle bacilli of the bovine type are not more commonly found in ordinary cases of phthisis?—I am, etc.,

London, W., March 29th.

J. WALTER CARR.

SLEEP AND WANT OF SLEEP.

SIR,—With reference to Dr. Farquharson's article on Sleep and Want of Sleep in the *JOURNAL* of February 27th, p. 522, it may be noticed that, of the expedients for inducing sleep, the contemplation of memorized percepts is the most successful. The contemplation in memory of objects perceived by the senses, principally (indeed, practically entirely) by sight, is to be aimed at, without considering their qualities or relations to each other, or

any attributes of them other than some one sensation which evidences their existence. The contemplation of mixed sensations, such as sight and taste, is not desirable—as, for instance, in a fruit. The percept contemplated must not be allowed to run on into a concept; the attributes or mutual relations of the objects so perceived must not be thought of.

Enumeration is useless as a device for procuring sleep, for we do not get this contemplation of simple concrete percepts, of objectivity, in dealing with numbers; there is no sense memory, but only contemplation of the relationships of abstract ideal entities. This is why counting or any consideration of numbers cannot be successful, for, to procure sleep we want to fill the mind with sense perception to the exclusion of ideation. The effort of contemplating motion as an attribute of the object perceived has also to be excluded; reading is worse than useless.

The higher phenomena of the scale of consciousness—emotion, ideation, etc.—have to be eliminated and set at rest. This is a form of the autohypnosis practised in the East. Contemplation of the memorized percept of a familiar locality—apart from any concept of attribute or incident—is a successful autohypnotic which becomes easy with practice.

Take, for example, the device of procuring sleep by contemplation of the memorized percept of the interior of Westminster Abbey, let us say, by one who is fairly familiar with it. In visual memory—not in imagination—he enters at the north transept and sees the rose window of the south transept as a blur of colour without detail. He sees statues—knowing them as Beaconsfield, Gladstone, etc.—subconsciously (a bad word but understood) without recalling them by conscious memory of detail. He advances to the centre and stands at the chancel steps, taking in the blurred percept of the Sanctuary and surroundings; turning, he has the vista of the choir and the west window over the screen; he then passes down the nave to the west door, and, turning, sees in the east the screen and organ, and beyond the clerestory lights of the apse. Then, slowly, up the aisle to the right of the choir to Poets' Corner in the south transept, without any conscious effort of memory to recall details. Then the South Ambulatory with into the chapels of St. Benedict, St. Edmund, and St. Nicholas, up to the Confessor's shrine—slowly, slowly—then to Henry VII Chapel to the flagstone marked Cromwell at the extreme east; to the aisle on the right, with the tomb of Mary Queen of Scots and tombs of Queen Anne and her husband, of Charles II, and of William and Mary; the aisle on the left with Queen Elizabeth's tomb, and that of the murdered princes; then to the North Ambulatory, and into the chapels of St. Paul, St. John the Baptist, and the Insipid Chapel.

The time occupied in memorizing all this mass of perception will be longer if one is intimately conversant with what there is to see, and shorter if there is only a slight knowledge of the place; but it may well occupy half an hour, by which time one would probably be asleep. Any other place may answer the same purpose—the Tower, St. Paul's, a provincial cathedral, or other interior familiar enough to be memorized without effort—a familiar highway from one town to another, the streets from one part of a town to another part, as long as motion and incident are excluded, and the percept kept from wandering into a concept. Emotions and ideas have, of course, to be quite excluded, and this is attained by practice.

One may have a *répertoire* of interiors or itineraries, and make a selection of a favourite one soon after he lays his head on his pillow; but having made a selection he must adhere to it, and not jump from one to another.—I am, etc.,

JOHN MARTIN,

London, W., Feb. 28th.

Lieut.-Col. late R.A.M.C.

THE NATIONAL SERVICE LEAGUE AND THE MEDICAL PROFESSION.

SIR,—I am glad to see Dr. Cowley's letter of March 27th. I have been a member of the Executive Committee of the league, and I speak for them whenever I can. I wish the members of our profession would support the league. In my opinion, no measure would do more for public health or for public morals than an Act which obliged young men to go through a few months of physical training and military discipline.

Let me remind you of the words of the *Spectator* after watching the six months' training under Colonel Pollock of its experimental company:

We have always believed that such training, could it be brought about, would be a great benefit to our population; but we now realize that the benefit is so enormous that every effort should be made to endow the whole of the youth of the nation with physical training of a kind similar to that undergone by the *Spectator* Company, and to make it as universal as the literary education imposed upon our children by the Act of 1870. . . . We think that we do not need universal service from the military side, but we have also come to realize that universal military training is, on the moral and physical side, so beneficial that we do not think it ought to be withheld from the young men of Great Britain (*Spectator*, September 15th, 1906).

I do not agree with the *Spectator* about our military needs, but his opinion on that point makes his testimony all the more valuable on the others.—I am, etc.,

London, W., April 1st.

W. P. HERRINGHAM.

RURAL DISTRICT NURSING ASSOCIATIONS.

SIR,—I can fully endorse the remarks contained in the letters of Dr. Wm. Milligan and "Parish Doctor" published on March 13th and 20th, on country district nursing associations. In one of the villages in which I practise the Lady Bountiful (of whom the inhabitants live in awe) insists on the poor and the small tradespeople subscribing to her pet hobby, the nursing association, in spite of the protests of some of her victims that in times of illness they are put to a double expense—the nurse, who comes in for a few minutes a day, and the neighbour, who is capable of, and really does, all the nursing of the patient, in addition to the work of the house and looking after all the other members of the family, as under the old régime.

This district nurse, who "practises" in four of my villages, has received six months' general training only, and is empowered and instructed by her committee, not only to attend any medical or surgical case on her own responsibility, but also to do her utmost to persuade patients not to call in a medical man, with the result that this unqualified practitioner attends cases of erysipelas, measles, and scarlet fever at the same time as she is nursing midwifery patients. Recently, in one week, two of her patients were "found dead in bed," without having been seen by a medical man. In both cases I was asked to give a certificate of death, which I naturally refused to do. On the first case, a single woman aged 60, an inquest was held, and I was ordered by the coroner to make a *post-mortem* examination. I found that the patient had been suffering from fatty degeneration of the heart, but only to such extent that with proper care her life might have been prolonged some years. Owing, I presume, to the fact that the jury was composed solely of strong supporters of the District Nursing Association, the nurse was not even called as a witness, and the fact that she had attended the deceased was afterwards hushed up. Upon the second case, not even an inquest was held, the coroner giving a certificate.

If two such flagrant cases as these can be thus treated, it is evidently hopeless for a medical practitioner to fight single-handed. Perhaps the fact that I have no near colleague to support me increases my difficulty; but truly she is a keen competitor to be reckoned with, and I myself have suffered, not only from her activity, but also the loss of several of my patients (who are members of the local nursing committee or their friends) because I refuse to support and cover this dangerous "unqualified practitioner."

It is certainly time that something was done by united action to safeguard both the public and the qualified medical practitioner, and I for one would gladly support any such movement.—I am, etc.,

March 24th.

COUNTRY PRACTITIONER.

THE MEDICAL PROFESSION AND LIFE ASSURANCE.

SIR,—My attention has just been called to an address on "The Medical Profession and Some Life Assurance Companies," delivered by J. Farrar, M.D., of Gainsborough, and reproduced in the SUPPLEMENT to your issue of November 28th, 1908. If it is not too late, I should like to make a few observations on some of the statements appearing therein.

Now, in the first instance, I have no wish to minimize in any way the importance of the work done by the medical profession for insurance companies. I admit, too, that it is done, with a few exceptions, conscientiously and with thoroughness. The real question is, Are the fees paid by life offices adequate and reasonable? It is to that I wish to address myself, and at the outset protest strongly against Dr. Farrar's suggestion that there is any attempt on the part of the life assurance companies to "sweat" the profession. I have had considerable experience of insurance companies, and I know that it is their practice to pay a fee of £1 ls. in the case of the larger insurances. In the case of small insurances of, say, £100 or £200, however, the fee is limited to 10s. 6d., and it is to this limitation, I presume, that Dr. Farrar objects. If he will look at the rates of premium charged by the average company he will find that the amount payable yearly by a proposer of, say, age 30, for a policy of £200 would be about £4; and when it is remembered that out of this first premium must be paid agent's and overriding commissions, policy stamp, head office and branch expenses, as well as the medical fee of 10s. 6d., it will be seen that there is very little remaining to cover the cost of the risk of death. But how much more difficult is it to adjust matters when, say, only a quarterly premium is paid on the assurance? This quarterly premium would amount, in the case of an assurance of £200, to approximately £1; in the case of an assurance of £100 to, say, 11s. Here, then, is nearly the whole of the first premium swallowed up by the payment of the medical fee, with the possibility that before three months have expired the assured may have changed his mind either as to the desirability of assurance generally or the company to which he proposed in particular, the policy lapsing as the result. It may be said that the cases I have taken are extreme examples, but the Blue Books issued by the Government will prove to your readers that the average amount proposed for is not in excess of £200.

If it is impossible to pay a larger fee in these cases, how much more so would it be in the case of small industrial assurances? Here the practice is to pay a fee of only 2s. 6d., and an examination is insisted upon in cases where the sum assured is £25 and the premium only 2d. or 3d. a week. Again, it will be seen that the medical fee exhausts the company's receipts in respect of that particular case during the whole of the first ten or fifteen weeks, and that the company is obliged to wait patiently until the expiry of that period before it has a chance of recouping itself for the money spent in expenses and on agent's and procurator fees, which are so much higher in the case of industrial assurances than in respect of proposals of £100 and upwards, with the prospect that the policy may lapse, as so many do, before even the medical fee is covered.

Dr. Farrar suggests that very frequently large sums are lost to the companies through early industrial claims which would otherwise be prevented by the expenditure of a guinea on medical examination. How much greater, and how much more certain, would the loss to the companies be if an expense of this kind were to be incurred in connexion with those cases! As a matter of fact the companies would all prefer to have a medical examination in every case, but the cost, as has just been shown, is prohibitive.

Instead of the profession being "sweated," I think it will be admitted by reasonable men that it is generously treated by the offices; and I would warn the members of the profession that if any change is instituted in the present state of affairs it will rather be in the direction of employing medical men for certain areas who will give their whole time to the service of the companies for fixed salaries, and thus perform more economically the work which is so widely distributed at present at such a considerable expense.

May I make one further remark—a reference to Dr. Farrar's suggestion that members of the profession, when asked by patients to give advice as to the best office in which to insure, should follow his lead and recommend only those offices which, in his opinion, pay adequate remuneration for professional service? Evidently his conscience, which he told his audience, in almost the same breath, would not allow him to perform half-heartedly the work done for those companies who paid him insufficiently,

was not alert enough to suggest to him that where advice was asked for by a confiding client it should be given solely with a view to the best interests of that client, and that the best company from a policy-holder's point of view should be selected, without regard in the slightest degree to whether the doctor was consulting in any way his own interests in making the selection.—I am, etc.,

Liverpool, March 12th.

A. A. SNODGRASS, F.C.I.S.

Universities and Colleges.

UNIVERSITY OF EDINBURGH. SPRING GRADUATION CEREMONIAL.

THE Spring Graduation Ceremonial took place on Friday, April 2nd, at 10 a.m., when the Vice-Chancellor, Principal Sir William Turner, presided.

The degree of Doctor of Laws was conferred on Mr. J. M. Barrie, Emeritus Professor Crum Brown, and Surgeon-General Sir Alfred Keogh, K.C.B., Director-General of the Army Medical Service, and the degree of Doctor of Science in the Department of Public Health on William Burney Bannerman, M.D., B.Sc. (Lieutenant-Colonel, I.M.S.).

Ordinary Degrees.

The following were presented by Professor Harvey Littlejohn, Acting Dean of the Faculty of Medicine, for the degrees of Bachelor of Medicine and Bachelor of Surgery:

C. R. White (*in absentia*), W. Rainbridge, J. H. Bell, J. P. Charles, W. C. Frango, K. Fraser, D. M. Grant, J. A. Harley, J. Hewat, V. D. O. Logan, A. S. Macbeth, D. McCarroll, G. M. Mackay, M. A. J. MacKenzie, A. C. McKillop, A. K. MacLachlan, W. M. Menzies, H. L. Morrow, W. G. Riley, Eleanor M. Thompson, N. J. Watt, W. C. Whiteside.

The degree of B.Sc. in the department of public health was conferred on J. R. Dickson, M.B. (*in absentia*); and the diploma in Tropical Medicine and Hygiene on S. A. McCintock, S. M'Naughton, and H. L. Sells. Professor Kirkpatrick delivered the address to the graduates on reform in the Faculties of Arts and Law.

Examination Results.

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.: *Forensic Medicine and Public Health*.—Janet Armstrong, J. G. Boal, W. Dunlop, T. R. Evans, R. V. Greatorex, R. R. Kerr, C. G. Kurien, W. G. M'Alae, A. C. McInzie, Mary Macmillan, R. F. Panton, H. R. A. Philp, S. P. Fenton, J. P. du Plessis, Ella F. Pringle, C. S. Sandeman, Welsch, J. M. Midwifery.—T. A. Adams, Janet Armstrong, Evelyn R. Benjamin, L. A. P. Burt, A. Campbell, J. P. Charnock, H. A. Cookson, J. Crockett, W. Dunlop, R. V. Greatorex, E. E. Guthrie, R. R. Kerr, C. G. Kurien, Lina Kurz, Janet Leiper, L. Leslie, H. Lipetz, W. G. M'Alae, R. B. Macfie, A. D. M'Kenzie, A. G. Macleod, R. J. A. Macmillan, G. M. Miller, J. M. Moyes, Rhoda M. Murdoch, W. J. Nisbet, F. H. Noronha, H. R. A. Philp, G. R. P. S. Panton, J. P. du Plessis, A. A. Reid, J. E. Renwick, Agatha M. Robinson, A. C. Russell, C. S. Sandeman, J. M. Scott, J. D. Skinner, Mary M. M. Turpie, T. Welsh, S. Williams.

Medicine and Surgery.—T. A. Adams, F. Armstrong, Alice E. M. Hamilton, B. A. T. H. Enfour, K. A. Holt, F. J. Brodzick, G. S. Brown, A. N. Bruce, B.Sc., W. F. Buist, O. S. Bulloch, W. L. Burgess, L. A. P. Burt, A. W. Burton, Sarah E. Buyers, J. Agvill Campbell, G. L. Cawthell, R. B. Chamberlain, A. D. Child, J. Crockett, J. E. M. Dickie, Adelaide A. Dracop, H. G. Felltham, G. F. Fismar, E. L. Galletty, Mary M. Gardner, A. W. Gill, W. E. Goss, W. T. Graham, A. G. M. Grant, A. G. Hamilton, H. F. Hamilton, R. C. Harkness, T. E. Harwood, B.A., J. Henderson, G. R. Inglis, Flora Jones, W. C. Jardine, A. M. Jones, G. E. King, J. H. Lawry, L. Leslie, H. Lipetz, W. R. Logan, Mary Low, M.A., H. F. Lumsden, D. C. Macaskill, M.A., A. J. McConnell, W. Macdonald, J. Mackail, M.A., C. E. G. Mackay, A. D. Mackenzie, A. G. Macleod, R. J. A. Macmillan, A. J. Macvie, J. Malloch, G. G. Marais, T. H. E. Mathewson, W. Messer, E. L. Middleton, A. F. W. Miller, A. M. Minford, L. M. V. Mitchell, S. P. Moore, W. Morrison, J. A. Mortimer, J. M. Moyes, R. M. Nicholson, W. J. Nisbet, H. R. A. Philp, J. Renwick, D. G. Robertson, W. S. Robertson, D. M. Ross, R. P. Rosser, C. M. Schaffer, J. M. Scott, J. J. M. Shaw, M.A., K. Simpson, G. H. Sinclair, H. F. Smith, B.A., T. C. Smith, G. S. Sowden, M.A., J. Spent, B.Sc., W. Stevenson, M. Stewart, W. Stewart, C. P. S. Stranghan, J. Stewart, A. L. Taylor, B.Sc., H. W. Teague, J. A. Thompson, W. S. Thomson, Mary M. M. Turpie, A. Watson, J. P. Whetter, J. Wilson, J. D. Wilson, M.A., Margaret C. Young.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—J. Allan, J. G. Anderson, W. H. S. Armstrong, D. M. Borland, M. W. Browdy, J. A. G. Burton, J. Cameron, M. I. T. Cassidy, W. B. Cunningham, J. C. Dick, A. G. Gilchrist, G. S. Gordon, E. O. D. Graham, J. Harper, M.A., V. Howat, M.A., J. P. Kinloch, D. N. Knox, A. M. Macdonald, M. D. Mackenzie, G. Macleod, M.A., A. M'Pherson, T. Martin, H. N. Rankin, A. Roenemele, W. W. Rorke, W. Rutherford, J. J. Sinclair, A. Turnbull, M.A., B.Sc., J. B. Whitfield, J. A. Wilson.

UNIVERSITY OF LEEDS.

THE following candidates have been approved at the examinations indicated:

FIRST M.B., CH.B. (*Part I*).—C. M. Gozner, H. R. Knowles, M. Peto, H. P. Shackleton, H. A. Sinson, H. Symons, H. M. Taylor, C. Ward, J. Wilkinson, and J. Wright.

SECOND M.B. (Part I. *Anatomy and Physiology*).—A. L. Bastable, H. Chablin, L. Dunbar, C. J. H. Eadie, G. B. Macvicar, N. V. Milton, F. W. Nunnally, V. Robinson, J. B. Sinson, J. P. Walker, T. L. Walker, F. Wigglesworth, B. W. F. Wood. Part II.—H. N. Ingham, C. B. Richardson.

UNIVERSITY OF DUBLIN.

The following candidates have been approved at the examinations indicated:

INTERMEDIATE MEDICAL (Part I).—A. Chance, F. Crosbie, O. C. S. Tandy, G. G. P. Beckett, H. G. Goldbrook, W. A. Taylor, S. A. Lane, R. G. McEntine, L. Shiel, J. C. Kelly.
INTERMEDIATE MEDICAL (Part II).—H. L. W. Woodroffe, R. W. Murphy, A. F. E. Shier, H. J. Smyly, F. C. Crossle, J. M. Elliott, H. M. Fleming, T. G. Harpur, A. E. Malone, O. Brien, Mary G. Caskey, G. J. Meldon, E. N. Bateman, G. G. P. Beckett, F. Crosbie, M. C. Knight, J. Beckett, R. C. B. E. H. Hughes, C. P. Smyly, H. R. Kenny, W. P. H. Smiley, D. Drew, J. P. R. Poch, B. H. Moore, W. R. Allen, C. G. S. Baroness, P. R. Lemass, D. H. Stokes, W. D. Mitchell, H. S. Mitchell, J. E. N. Ryan.
* Passed on high marks.

UNIVERSITY OF DURHAM.

The following candidates have been approved at the examinations indicated:

FIRST M.B. (All Subjects).—W. S. Murray.
Elementary Anatomy and Biology.—R. E. Bell, G. A. Berkeley-Cole, G. Carse, H. C. Dodd, C. Duncan, I. D. Evans, R. A. Hooper, R. L. Kitching, Nora Murphy, Carina A. B. O'Neill, A. Patterson, L. G. Pearson, J. M. Phillips-Jones, E. Risson, D. G. Scott, C. O. Shackleton, A. Seidlitz.
Chemistry and Physics.—F. Balst, P. Gunn, F. W. C. Hinings, S. E. Murray, C. T. G. Pearce, S. Scott, A. Smith, H. J. Shanley.
Chemistry, Elementary Anatomy, and Biology.—J. S. Arkle.
Elementary Anatomy.—W. A. Elliott.
SECOND M.B. (Anatomy, Physiology, and Materia Medica).—S. P. Bedson, B. S. C. F. Chapman, W. L. Clements, H. Fairclough, L. E. Gelle, J. K. J. Havorth, N. J. Hickey, E. E. Lidd, W. G. Liddard, C. Morris, B. B. Noble, J. A. C. Scott, W. A. Slater, R. W. Smith, R. V. Steele, H. R. G. Vander Beken.
THIRD M.B. (Pathology, Medical Jurisprudence, Public Health, and Elementary Biology).—V. C. Bende, B. G. H. Connolly, R. Errington, F. P. Evers, E. L. Hancock, H. T. Hunter, Eva Lumb, E. P. Martin, A. T. Thompson, T. R. West.
Second-class honours.

VICTORIA UNIVERSITY OF MANCHESTER.

The following candidates have been approved at the examinations indicated:

SECOND M.B. (Ch.B.).—R. D. Beag, C. E. Butterworth, C. W. Fort, A. H. Howell, L. W. Howarth, W. H. Leech, W. H. Leech, T. W. Martin, N. Matthews, F. Oppenheimer, H. G. Penke, S. B. Radley, J. Rothwell, C. M. Stallard, W. Scirling, J. S. B. Stoford, D. L. Whiles.
THIRD M.B. (Ch.B.).—A. E. Ainscow, R. Brierefield, S. J. Clegg, J. Cowan, C. Davies, C. B. Davies, H. A. Dunkerley, E. R. Easock, A. W. Gave, E. Grey, H. Heathcote, R. C. Hutchinson, R. B. Jackson, G. Lapage, Mabel E. May, A. Reid, J. R. Rigg, J. B. Scott, W. A. Seacht, J. Walker, Charles H. Warner.
FINAL M.B. AND CH.B. (Forensic Medicine and Toxicology).—H. E. Allanson, Estelle I. E. Atkinson, G. M. Benton, C. G. Brentnall, W. A. Bullock, J. F. Cocker, D. I. Connolly, G. T. Cressan, F. H. ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An extraordinary Comitia was held at the College on Monday, April 5th, the President, Sir R. Douglas Powell, in the chair.

University of Geneva.

The President announced that he had appointed Dr. Pasteur to represent the College at the commemoration of the 50th anniversary of the University of Geneva to be held in July next.

Presidential Address.

The President gave his annual address, in which he offered congratulations to the diplomates of the College who had gained distinctions, and referred to the lectures that had been delivered and the gifts accepted by the College during the past academic year. He gave brief obituary notices of ten Fellows of the College who had died during the same period, these being Drs. Cullingworth, Rickards, Bertram Abrahams, and Ashby, Sir T. Stevenson, Sir Henry Pitman, and Drs. C. E. Beevor, Horrocks, Cotes, and Arthur Gamgee.

Election of President.

Sir Douglas Powell then vacated the chair and voting took place for the post of President for the ensuing year. Sir Douglas Powell was re-elected by an almost unanimous vote.

Communications.

The following communications were received:

1. From the Secretary of the College of Surgeons, reporting

proceedings of the Council on February 11th and April 1st last.

2. From Miss Amy Maxwell, offering through Sir William Allchin for the acceptance of the College a photographic copy of a miniature portrait of her grandfather, Dr. Anthony Todd Thomson, a former Fellow of the College. The gift was accepted, and thanks returned to the donor.

Admission of Women to the Examinations of the College.

The following by-law was enacted for the first time:

Women shall be eligible for admission as Licentiate and Members of the College and for the grant of a Diploma in Public Health on the same terms and conditions as men, and so far as is necessary to give effect to this By-law, words in the By-laws and Regulations importing the masculine gender shall include females, and all proper alterations shall be made in the forms of the Letters Testimonial and the Licence granted by the College.

Provided always that women shall not be eligible for election as Fellows of the College, or be entitled to take part in the government, management, or proceedings of the College.

Anniversary of the Birth of Dr. Caisus.

The Harveian Librarian, Dr. F. Payne, announced that the year 1910 would be the 400th anniversary of the birth of Dr. Caisus, a former distinguished President of the College, and on his recommendation it was resolved to co-operate with Caisus College, Cambridge, in reprinting the works of Dr. Caisus to commemorate the occasion.

Report.

A report was received from the Committee of Management recommending that the University of St. Andrews be added to the list of institutions at which the complete curriculum of professional study required for the diplomas of the Royal Colleges may be pursued, and whose graduates may be admitted to the Final Examination of the Examining Board in England on production of the required certificates of study.

The recommendation was adopted.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on April 1st, Mr. Henry Morris, President, in the chair.

The late Mr. James Hardie.

A vote of condolence was passed to the relatives of Mr. James Hardie, of Manchester, lately deceased, a past member of council.

Entozoa in the Museum.

Dr. R. T. Leiper, of the London School of Tropical Medicine, was appointed to revise and renovate the collection of entozoa in the College museum.

Jacksonian Prize.

The Jacksonian Prize was awarded to Mr. J. P. Lockhart Mummery, F.R.C.S., for his essay on Diseases of the Colon Relievable by Operation. The subject chosen for the next essay is Tuberculous Disease of the Urinary Bladder and Male Genital Organs.

Court of Examiners.

The vacancy on the Court of Examiners, occasioned by the retirement of Mr. Gould, will be filled up at the council meeting on May 13th. Mr. Gould is not applying for re-election.

The Geneva Celebration.

Sir Jonathan Hutchinson was nominated as the delegate of the College to the University of Geneva on the occasion of the celebration of the 50th anniversary of its foundation, from July 7th to July 10th, 1909.

Representative of Midwives Board.

The best thanks of the council were given to Mr. Ward Cousins for his very efficient services as representative of the College on the Central Midwives Board during the past six years. Mr. C. H. Golding-Bird was elected in Mr. Ward Cousins's place. In his annual report, Mr. Ward Cousins points out that the number of deaths attending childbirth has not diminished since the Midwives Act came into operation in April, 1903; no guarantee at present exists for the payment of medical practitioners who are summoned to assist certified midwives, in consequence of serious trouble in all parts of the country still exists; hence the Act requires considerable alteration. The details will be submitted to the Departmental Committee appointed by the Government, and, he reports, there is every reason to hope that the defects will be removed.

John Tomes Prize.

The John Tomes Prize was awarded to Mr. Arthur Swayne Underwood.

University of London.

Mr. H. H. Clutton was reappointed one of the two representatives of the College on the Senate of the University of London.

Election of Fellows.

The following Members of twenty years' standing were elected Fellows of the College: Sir Shirley Forster Murphy, Medical Officer of Health for the County of London; George Dancer Thane, Professor of Anatomy, University College, London.

Admission of Women.

The formulae for the alteration of Section XXI and for a new Section XXVI (Admission of Women) were approved, and the Solicitor of the College was instructed to submit the new by-laws to the proper authorities for sanction and ratification.

Medico-Legal.

INQUESTS ON CASES OF DEATH AFTER OPERATION.

THE following reports of inquests on cases of death after operation deserve, we think, to be brought to the attention of our readers. The inquests were held some time ago, but it is only recently that we have been able to obtain reports sufficiently full to show the mode of procedure adopted by the Coroner for Westminster and the South-West District of London. The reports, which are taken from the *South-Western Star*, have been in each case authenticated by the surgeon who operated. Mr. Sampson Handley informs us that the report of his case is quite accurate; Mr. Swainson has corrected the report of his case in one or two points.

MR. SAMPSON HANDLEY'S CASE.

The following report is abbreviated from the *South-Western Star* of January 1st, 1909:

Mr. Troutbeck held an inquest at the Battersea Coroner's Court on Monday (December 23rd, 1908) with reference to the death of Henry Fielder Trigg, a butcher, aged 53, late of 7, Eglantine Road, Wandsworth, who died at Boleingbroke Hospital on December 22nd, after a serious operation. Lionel Harry Trigg, mason, a son of the deceased, stated that his father had been in excellent health until three months ago, when he complained of internal pains. He was attended by Dr. Archer, of East Hill, for some weeks, after which he went to St. Peter's Hospital, Covent Garden, where he stopped a fortnight. Not getting any better he applied for and was granted admission to Boleingbroke Hospital. A week after his admission an operation was suggested, and the deceased agreed to it. Asked by the coroner if he understood that his father was in a serious condition, the witness replied in the affirmative. Asked further if he thought the operation would give him a chance of life, the witness said, Yes. Mr. W. Sampson Handley, M.S., F.R.C.S., surgeon at Boleingbroke Hospital and assistant surgeon at Middlesex Hospital, stated that when he examined the deceased the menses of the electric light he discovered a growth in the bladder. He cut open the bladder, thinking he could remove the growth, but found that it was irremovable, and that the only means was to remove the whole bladder. He knew this was an extremely dangerous operation, and explained this to deceased, who gave his consent for the operation to be performed. "I told him," witness said, "that I would not perform the operation except at his request." He was in a miserable condition. Asked by the coroner if that was an operation that was very often performed, Mr. Sampson Handley said it was performed sometimes. Continuing, he said that he performed the operation on December 22nd. He removed the whole bladder, and made an artificial one from a portion of the intestine. Deceased died shortly after the operation. The witness was not present when he died. Asked if the patient was under an anaesthetic, Mr. Sampson Handley said he was under a mixture of chloroform and ether. The cause of death, in his opinion, was partly due to the state of his health produced by the growth. The immediate cause of death was shock caused by the operation. "It was a cancerous growth. Asked by the coroner if he was able to form an opinion of the probable length of time the man would have lived if the operation had not been performed, Mr. Sampson Handley said "about two or three months, but he would have been in agony all the time." In reply to further questions, he said that if the operation had been successful it might have prolonged his life for years if there were no other growths in the body. Asked if there had been cases of a successful operation, the witness said "Yes; and the patient had been cured and has lived for years in comfort." Asked if he thought the anaesthetic affected the matter in any way, Mr. Sampson Handley replied that it was very hard to say. He did not think it did. Dr. Freyberger, who made the post-mortem examination, stated that death was caused by sudden failure of the heart in consequence of the shock of a prolonged operation, while deceased was suffering from the effects of cancer. In reply to the coroner, who asked "As far as the history of the case, if the operation is concerned, is it one that has been performed for any considerable time?" the witness replied: "About fifteen years I should say." The coroner (addressing the jury) said that there could be no doubt that Mr. Handley was justified in undertaking the operation in the circumstances. The jury returned a verdict of "Accidental death."

MR. SWAINSON'S CASE.

The following corrected report is abridged from the *South-Western Star* of January 25th, 1909.

On Wednesday (January 27th) an inquest was held at the Battersea Coroner's Court before Mr. Troutbeck on the body of James Arthur Searle, aged 8 years, whose parents live at 8, Winifred Grove, Battersea. On the previous Saturday deceased underwent an operation at Boleingbroke Hospital, and died soon afterwards. James Searle, a compositor, identified the body as that of his son. He had had fair health, but Dr. Wallace had attended him for about two years. On Thursday deceased complained of pain in the stomach, and witness

thought it was ordinary stomach-ache. The child had not eaten anything unwholesome as far as witness knew. That night he saw a doctor and described the symptoms. Some medicine was prescribed for him. Next day the boy seemed better. On Saturday morning he was very bad, and when witness had gone to work his wife called in the doctor. When he got home at dinner time witness found deceased was worse. The doctor came about 4 o'clock, and diagnosed the case as one of appendicitis, and advised removal to a hospital for operation. The boy was hurried off to Boleingbroke Hospital in a cab, and handed over to the doctors for the purpose of an operation. About 6 o'clock witness was informed that deceased had died, having been in the hospital about an hour. (The time was really about two hours.) In reply to the coroner, who asked when he handed the boy over to the doctors if he thought he was likely to die, the witness said he thought an operation was his only chance. Asked if he had anything else to say about the death, he said, No. He thought the hospital authorities did their very best, and did it well. All he complained of was the inquest. The coroner said: "It is a duty. I am afraid every one has to obey the law, even if it is disagreeable." Annie Marie Searle, the mother, agreed with her husband that the deceased was taken to the hospital as the only chance of saving his life. As a matter of fact, she thought he was dying before he was taken away. Dr. J. B. Vallar, 117, North Side, Clapham Common, said deceased was a very delicate boy, and of exceedingly poor physique. When the child was brought to him suffering from the stomach-ache he thought it was an ordinary bilious attack. When he saw deceased on Saturday afternoon he was in a state of collapse. The boy's condition struck him as that of appendicitis, and an immediate operation was the only chance of saving his life. Dr. Atkin, medical superintendent at Boleingbroke Hospital, said deceased was admitted shortly after 4 o'clock on Saturday. He was suffering from what was known as an "acute abdomen," which was swollen. He told the parents that an immediate operation was the only chance of saving the child's life. They consented, and the child was got ready. He was given chloroform with a slight mixture of ether. He took it very nicely and needed very little anaesthetic. The abdomen was full of blood-stained fluid. A gangrenous portion of bowel was removed and the bowel drained. The whole thing took twenty-five minutes, and the deceased died quietly at the finish. He was removed to the ward about 5.35 and died about 10 minutes to 6. Death was due to strangulation of the bowel and peritonitis. The operation shortened his life by a few hours. If he had remained at home he would have lived about six hours. Mr. Swainson, Surgeon to Boleingbroke Hospital, and Assistant Surgeon to the Westminster Hospital, said he undertook the operation. It was clear that deceased had peritonitis, which was probably caused by appendicitis. When he opened the abdomen he found it full of blood-stained fluid, which made the case very grave indeed. In his opinion death was due to peritonitis and toxæmia. After the child was admitted in a collapsed state he had reacted to restoratives, and it was hoped that after the operation he would again react to restoratives, which were applied, but with no effect. Therefore there was small chance of saving the child's life. Dr. Freyberger said death was due to failure of the heart in consequence of collapse caused by the gangrenous state of the bowel. He could not entirely dissociate from the death the shock caused by the anaesthetic. The coroner said that, although objection was sometimes taken by relatives and others to the holding of inquests, the law was perfectly clear on the subject, and the duty of attending inquests and giving evidence, although it might be disagreeable, was one which had to be faced. These inquiries were primarily for the benefit of the public, but they were, perhaps, of even greater benefit to medical men who had conducted operations, and who were given this opportunity of seeing that they had taken the right course. It was a great satisfaction to them to hear a jury express approval of their efforts at a public inquiry. In this case the operation was fully justified, and death could not reasonably be prevented. The jury returned a verdict of "Accidental death."

UNREGISTERED DENTISTS.

IN our last issue proceedings against the Hygienic Institute were reported in two cases in which damages were claimed and awarded.

At Bishop Auckland Petty Sessions on April 1st, Robert Smith, local manager of the Hygienic Institute, was summoned, at the instance of the British Dental Association, for having unlawfully represented himself to be a duly qualified and registered dentist, contrary to the Dentists Act, 1878. Mr. R. Luck, barrister, instructed by Mr. W. Wilkinson, Bishop Auckland, prosecuted; and Mr. Mundahl, barrister, instructed by Mr. R. S. Holmes, Newcastle-on-Tyne, defended.

Evidence was given by two police constables, who, disguised as workmen, visited the local branch of the Hygienic Institute, at the door of which was a plate bearing the inscription, "Hygienic Institute, Makers of High-class Artificial Teeth." On a landing inside the house was a board with the words, "Hygienic Institute. R. Smith, manager."

Constable Pakes said when he went in he asked for the dentist, when the defendant appeared. He said to him, "Are you the dentist?" the reply of Smith being, "I am." Smith examined his mouth and advised him to have a tooth drawn. Witness asked if it would cause pain, and Smith replied that he thought he could take it out absolutely painlessly, and that

the price would be a shilling. He was shown into a room marked "Private," where an operator named Macdonald assured him there would be no pain whatever, but added that he would inject some stuff into the gum as a precaution, as it would deaden any pain. Smith held his head while the extraction was taking place. Afterwards Macdonald asked him if he would have another tooth drawn, as there was one which ought to come out, but witness declined.

Constable Parkinson corroborated. He said the extraction took place under Smith's supervision. As to his own teeth, when Smith had examined his mouth, he said, "You are a case for the 'Hygienic,' you are all yours want to come out. I will cut in a full set, top and bottom, for £5." Witness said that was a lot of money, whereupon Smith said that he could pay a certain sum down and the remainder the collector could call for at the rate of 3s. a fortnight. He asked Smith what that stuff was that the operator had injected into his chum's gum, and Smith replied: "That is a trade secret. Any dentist in Bishop Auckland would give £100 to know what it is."

Mr. Jonathan Townend, Bishop Auckland, who laid the information on behalf of the British Dental Association, proved that neither Smith's nor Macdonald's names were on the *Dentists Register*.

Mr. Mundahl submitted that the defendant had not implied that he was a registered dentist. He contended that any one could supply artificial teeth. Defendant was not a dentist, but simply a business manager, and had never represented that he was qualified.

Defendant stated that he had never been a dentist, and had never drawn a tooth. He would never think of representing that he was a dentist. He did not tell the men that he was a dentist, nor did he say that the teeth would be drawn painlessly. He never supposed that what he did would lead to the supposition that he was duly qualified. In cross-examination by Mr. Luck, defendant said he had been in the service of the Hygienic Institute for about a year, and at Auckland since November. Before that he was a traveller. He appeared reluctant to say in what line of business he had travelled, but, when pressed, he admitted that he had represented a firm of wholesale fruit merchants. He declined, by advice of his counsel, to answer the question as to whether there was a registered dental practitioner on the premises at Bishop Auckland.

Mr. Luck: Is it part of the business of the institute to extract teeth painlessly and to use an anaesthetic?—Witness: We extract teeth and use an anaesthetic.

Is it part of the business of the institute to extract teeth painlessly?—It is our duty to give as little pain as possible.

If you had nothing to do with the operation, why did you stay in the operating room?—Because I had a right to be on the premises.

Why did you go there if you had nothing to do with it?—The operator is under my instruction with regard to his work.

The bench fined defendant £5, with £3 15s. costs, including the prosecuting counsel's fee, and declined to state a case for a High Court on the question of the defendant's representation that he was a dentist, having found it a fact that he had done so, but agreed to state a case on a question of law.

A second summons against the defendant in respect of P.C. Parkinson was withdrawn on payment of costs.

FEES OF MEDICAL WITNESSES.

N. F. writes that he is likely to be called in a divorce case as a medical witness to prove cruelty, but has not yet received a subpoena. He wishes to know whether there is a fixed scale for medical witnesses, or has the amount to be a matter of arrangement between the doctor and solicitors.

* * * There is a fixed scale laid down by the court, and our correspondent, if legally subpoenaed, could recover his fees on that scale. But it often happens that the fees allowed on this scale are insufficient to repay the medical witness for his time and labour. Where this is the case the medical witness should have a written agreement from the patient or his solicitors to pay him his charges when they are in excess of the authorized scale.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

COMMISSION TO ASSISTANTS.

ORNTS asks at what rate commission is paid to an assistant for extra work, such as midwifery, introducing fresh patients, etc.

* * * The salary of a medical assistant should be inclusive of everything. In some cases a small percentage is allowed by the principal on midwifery, but we have never heard of any commission being paid for the introduction of patients.

CONDUCT OF MEDICAL OFFICERS OF ACCIDENT INSURANCE COMPANIES.

J. C. E.—We have repeatedly drawn attention to the obligation which rests upon the practitioner sent on behalf of the employer or insurance company to give notice to the patient of his intended visit, so that the practitioner's attendance can be present. The omission to give this notice is to be deplored, as such unannounced intrusion invariably gives offence and wantonly disturbs the harmonious relations that should exist between members of the same profession.

THE ETHICS OF CONSULTATION.

M. S.—Our correspondent appears to have acted with courtesy and consideration, and we can only explain the medical attendant's failure to write by his misunderstanding his position in the matter. It is easy for a consultant to ignore the medical attendant on the ground that he did not know the patient was under the care of another practitioner; but if, when he follows the better rule, he does not meet with courtesy he will be disposed to agree with those consultants who urge that when a patient comes without an introduction from a doctor the question of any previous medical attendance should not be raised. This is deplorable, but for the fact that such a plea can be put forward, those general practitioners who refuse to co-operate when approached, and still more those who write indignantly complaining that their patient should be seen at all without their permission, are chiefly to blame.

SUPERSESSION.

TOXAEMIA.—A. had attended a patient for whom a slight operation was necessary, and who had consented to go into hospital for the performance of it, but she went to see her mother, who took her to B, the family doctor, without telling him that A. had seen the patient. B. recommended an operation, and offered to perform it at the mother's house. The mother called on A. to apologize. A. told her that B. should be informed that he had been in attendance for two or three weeks upon the patient. This was done, and B. then telephoned to A. to say that he had not known of his attendance when he offered to perform the operation. We are asked to say what B. ought to do.

* * * B. should explain that he ought to have been told, and cancel any arrangement already made, but the question as to where and by whom the operation should be performed must be left to the decision of the patient.

Obituary.

ARTHUR GAMGEE, M.D. EDIN.,

F.R.C.P. EDIN. AND LOND., F.R.S.

EMERITUS PROFESSOR OF PHYSIOLOGY, OWENS COLLEGE, MANCHESTER. PROFESSOR ARTHUR GAMGEE, whose death during a visit to Paris was briefly announced last week, was born in 1841, a younger son of Mr. Joseph Gamgee, a veterinary surgeon of Edinburgh, distinguished for his researches, particularly with regard to rinderpest.

Arthur Gamgee was educated at University College School, and at the University of Edinburgh, where he graduated M.D. in 1862, being awarded the gold medal for his thesis. He became lecturer on physiology at Surgeons' Hall, Edinburgh, and physician to the Royal Hospital for Sick Children. He was also assistant to the professor of medical jurisprudence at the University of Edinburgh from 1863 to 1869, and at this time began his researches on haemoglobin and the pharmacology of the nitrites.

In 1872 the Royal Manchester School of Medicine was incorporated with the Owens College, and in the following year Dr. Gamgee was appointed the first Professor of Physiology in the College, and set to work to develop the department with characteristic energy and enthusiasm. The number of students at that time was small, but Professor Gamgee was not discouraged by this circumstance; he proved himself an inspiring teacher, and among his pupils are many who have since attained to eminent positions. At the time when Gamgee became professor at Manchester there was a dearth of textbooks on physiology, and in 1875 he published a translation of Hermann's *Human Physiology*, which was very generally adopted as a textbook, and which reached a second edition in 1878. He was Dean of the Faculty of Medicine, and Physician to the Manchester Hospital for Consumption and Diseases of the Throat; he was President of the Section of Physiology at the annual meeting of the British Medical Association in Manchester in 1877, and delivered an address on recent advances in physiology, which was largely concerned with the then new observations on digestive ferments, especially trypsin, and with

the electric current in muscles. He early turned his attention to the chemical side of physiology, and in 1880 published the first volume of his important work, *A Text-book of the Physiological Chemistry of the Animal Body*, the second volume of which did not appear until 1893, and embodied investigations which he conducted in the laboratory of his friend Professor Hugo Kruonecker at Berne.

Soon after the appearance of the first volume of this work, Gamgee decided to relinquish the teaching of physiology and to devote himself mainly to the practice of medicine, and with this object in view he resigned the Brackenbury chair at Manchester and migrated to London, where he obtained the appointments of Assistant Physician and Lecturer on *Materia Medica* at St. George's Hospital. But in spite of some success in practice in London, he was compelled by ill health before very long to resign his hospital appointments and to seek opportunities elsewhere. After trying one or two localities in this country and in Switzerland he finally settled down in practice in Montreux, and it was here that most of the remainder of his life was spent. Three or four years ago, however, he was attracted by an offer from the Carnegie Institute of Washington to inspect on behalf of the institute the facilities for conducting researches in metabolism, calorimetry and allied subjects which were to be found in European universities, with a view to reporting on the best mode by which investigations might be carried on by the institute. He accordingly gave up his practice in Switzerland and spent several months in this, to him, congenial task. On the completion he was so deeply interested in the subject of animal heat and calorimetry that he set to work, with the aid of Mr. Horace Darwin and the Cambridge Scientific Instrument Company, to devise a means of continuous registration of the temperature of the human body, and upon this he was in fact engaged at the time of his death. An account of his apparatus together with some preliminary results, was published last year in the *Philosophical Transactions* (see also this JOURNAL of December 3rd, 1908).

But scientific investigations are not an adequate means of livelihood in this country, and Gamgee was constrained once more to settle down in practice in London, whilst continuing in Dr. Waller's laboratory at the University of London the work on temperature with which he had already achieved interesting results at Cambridge—a project which has been frustrated by his untimely death.

From 1882 to 1885 Gamgee was Fullerian Professor of Physiology at the Royal Institution of Great Britain. He was a Fellow of the Royal Society, and in 1902 delivered before it the Croonian Lecture on the chemical and physical properties of haemoglobin. He was elected Fellow of the Royal College of Physicians in 1896.

He was an honorary LL.D. of the University of Edinburgh, and last year received the honorary degree of D.Sc. from the University of Manchester. In the course of the observations with which he was presented for this degree, Professor Lamb said: "In Arthur Gamgee we welcome an old colleague who for many years illustrated the Chair of Physiology in the Owens College, and whose services in the establishment of the former Victoria University and in the securing of its medical charter are not lightly to be forgotten."

He was an accomplished linguist, and was selected by the Council of the Royal Society to represent that society at Berne last November on the occasion of the bicentenary celebration of the birth of Albrecht von Haller. The lecture-address which he presented on behalf of the society was composed by himself and delivered with the purest Italian pronunciation in a characteristic dramatic manner, which produced a great effect upon the large and distinguished audience which had assembled to do honour to the father of modern physiology.

Dr. J. G. McKENDRICK (Emeritus Professor of Physiology in the University of Glasgow) has written the following in response to our request: The foregoing account of the leading events in the life of Arthur Gamgee, accurate as it is, cannot convey an adequate idea of the singular versatility and brilliancy of the man. The writer became acquainted with him about forty years ago. He was then justly regarded as one of the ablest of the younger men connected with the Edinburgh Medical School. Imbued

with a love of science for its own sake, he attacked many questions with youthful enthusiasm and energy. He was one of the first in this country to recognize the importance of the chemical investigation of some of the phenomena of life, and he prepared himself for work of this kind by becoming an expert analyst, more especially in the obscure domain of organic chemistry. He saw that the methods of du Bois Reymond, Helmholtz, and Ludwig had their limitations, and that new vistas of discovery and new methods of investigation were opening up to the physiologist. The training he gave himself in physics, and in physical methods, was also varied and extensive. In those days he was in close touch with such men as Peter Guthrie Tait, James Dewar, and Matthews Duncan, and no doubt he was inspired by their zeal and example. He rendered a great service to physiological science by translating *Hermann's Physiology*, the first textbook of physiology that gave due importance to the laws of the conservation of energy as applied to living beings. That book was, in a sense, epoch-making, inasmuch as it presented to the student many of the phenomena of life in a new aspect. Gamgee was an excellent teacher. He had an easy flow of language, sometimes almost too exuberant, and he spoke with the fervor of one who was deeply interested in his subject. His career after leaving Edinburgh was marked by many vicissitudes and trials, and not a few felt that his devotion to science and his rare intellectual gifts did not always obtain adequate recognition. This was largely due to peculiarity of temperament, and especially to a restlessness not infrequently associated with genius. No one can doubt that Gamgee had not a little of the speculative daring of genius combined with an indefatigable industry in experimental work. Altogether he was a singularly gifted man. An accomplished linguist in at least four European languages, he was also an excellent classical scholar, and, as has already been pointed out, he had a grip of physics and chemistry, in their bearing on physiological questions, such as is possessed by few. But it was his fiery enthusiasm that was his most striking characteristic. In the privacy of domestic life, or in the street, he poured out his treasures new and old, and emphasized his points for or against the theory he was discussing, or the investigation in which he happened to be engaged. His meteoric brilliancy has now been quenched in the darkness, but there are many who will cherish it in their memory, and they will think of Arthur Gamgee as one of the most gifted men they have known.

Professor SCHÜTTER has responded to our request by the following appreciation: Having known Arthur Gamgee during the whole of my scientific life, I can say without reserve—and all his friends, who are legion, will agree—that to know him was to love him. Any faults he may have had were on the surface and so transparent that they never in the least concealed the real nature of the man, which was an embodiment of earnestness and sincerity. He was essentially impulsive and an enthusiast, and, like all enthusiasts, would for the time being become wrapped up in the matter in hand. In all probability it was this quality of mind which enabled him to work so successfully at the subject which might chance to engage his attention—witness his work on protagon, on haemoglobin, and on temperature. But enthusiasm has its disadvantages as well as its advantages, chief amongst the former being the tendency to overshoot the mark and arrive at a conclusion not always completely warranted by observation. If, however, this ever happened with Gamgee, he would himself be the first to acknowledge the error, for he was truthfulness itself. Gamgee was a brilliant conversationalist, possessed of erudition far above the average, and of an originality which might almost be said to constitute genius. His loss will be felt by physiologists all the world over, and his friends will long miss his striking personality and the sympathetic interest which he took in their work and welfare.

C. ERNEST BAKER, M.B., B.C. CAMB., F.R.C.S. ENG.,
RESIDENT.

On Sunday, March 28th, the death occurred of Dr. C. Ernest Baker under very sad circumstances. He died at 5, Gledhow Gardens, South Kensington, where he had been in practice for the last fourteen years. He had not for some time been a good sleeper, and was occasionally

much troubled with sleeplessness, but only very rarely, and under medical advice, did he take any narcotic drug. On Friday, March 26th, a medical friend strongly advised him to take a dose of veronal, but he did not do so that night. On Saturday, March 27th, on going to bed he took a tablet (5 grains) and a half of veronal, and slept all through the night. At 8 a.m. on the following morning it was impossible to rouse him. In spite of the untiring efforts of two medical friends, he never recovered consciousness, and died at 2.30 p.m. the same day. The news of his death came as a great shock to his friends, as up to the last he had been actively engaged in his practice, which had never been interrupted by ill health.

Charles ERNEST BAKER was born in 1864, and went up to Cambridge from Haileybury in 1883. He graduated B.A., taking a first class in the Natural Science Tripos in 1886. In 1886 he entered St. Bartholomew's Hospital, where, after a most successful career as a student, he held the office of House-Surgeon. He took the degrees of M.B., B.C. in 1890.

He held resident appointments at the Royal Free Hospital, the East London Hospital for Children, and the Royal Orthopaedic Hospital, and in 1893 took the diplomas of F.R.C.S. Eng., and the D.P.H. Camb. He married in 1895 Ada Marion, third daughter of Sir Thomas Smith, and began general practice at 5, Gledhow Gardens. Always eager to qualify himself as fully as possible for his life's work he worked as Clinical Assistant at the Royal Eye Hospital, Southwark, for four years whilst in practice.

Charles Ernest Baker was beloved and respected by all who knew him for his kindly, simple, and straightforward nature. These strongly marked characteristics, together with his ability, sound commonsense, and whole-hearted zeal for the welfare of his patients, made him an ideal general practitioner. His memory will remain with those who knew him as that of a man of the most lovable disposition, who took his profession seriously, and having sought strenuously to qualify himself for it, went straight forward in his practice of it with unflinching good judgement, probity, and kindness of heart.

MAJOR JOHN SIMPSON EDYE, late R.A.M.C., who died from cholera at Bengal on February 22nd, was the eldest son of Captain J. Ebye, C.B., R.N. He took the diplomas of L.S.A. in 1885, M.R.C.S. Eng. in 1886, and L.R.C.P. Lond. in the following year. Major Ebye entered the army in 1886 and retired in 1907; he saw active service in the South African war, receiving the Queen's medal and four clasps. He held the appointments of Special Plague Health Officer, and Senior Medical Officer at Cawnpore.

MR. JOHN KERSHAW, formerly of Royton, died on February 14th, in his 68th year, at his residence at St. Anne's-on-Sea, where he had lived since his retirement. He received his medical education at Manchester, and obtained the diplomas of L.R.C.P. Edin. and L.F.P.S. Glas. in 1867, and that of L.S.A. in 1868; in 1874 he became F.R.C.S. Edin. He was formerly medical officer of health for Royton and was a member of the British Medical Association. His will which has now been proved contains directions of general interest. Apart from a request that his remains be cremated without religious ceremony and that no outward sign of mourning be displayed at his house or by any of his relatives or friends, the will establishes a trust for a sum arising from the residue of his estate. This is estimated to be about £50,000, and is to be devoted towards the establishment and maintenance of a general hospital and infirmary in the township of Royton, and if possible on some part of the testator's Sunfield estate. The institution is to be free to all applicants, no inquiry being made as to their religious beliefs or practice. Furthermore, no clergyman or minister of religion, nor any socialist or person known to hold or profess socialist opinions, can at any time be a trustee, director, or manager of the institution to be established.

THE Turin Academy of Sciences offers a prize of £372 for the most important discovery or the best work in the domain of physics, natural science, or physiology. Intending competitors must send in their statement of claim on or before December 31st, 1910.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Richmond (Surrey).—The Medical Officer of Health (Dr. J. H. Crocker) states that the population in 1908 was 35,415, the birth-rate 17.2, and the death-rate 12 per 1,000. The infantile mortality-rate was equal to 106 per 1,000 births. Of the 65 children who died under 1 year old, as many as 56 were under the age of 6 months. In the last quarter of the year an outbreak of scarlet fever among children attending public elementary schools resulted in the notification of nearly 100 cases of the disease, of which number 86 per cent. were removed to the isolation hospital. Several schools were closed for short periods, but Dr. Crocker is of opinion that the chief cause of the spread of the disease throughout the district was the difficulty in getting hold of unrecognized cases. The disease was of so mild a type that the nature of the illness was not realized until the peeling stage had arrived. Appended to the report is a section dealing with the cleansing of schools. Dr. Crocker states very clearly how the school cleaners should carry out their duties, and the school managers will be well advised if they insist upon the work of the cleaners being carried out in the manner suggested by the Medical Officer of Health.

Borough of Keighley.—Calculated on an estimated population of 45,720, the birth-rate was 20.6, and the death-rate 14.5. The infantile mortality-rate was equal to 134 per 1,000 births. The most noticeable feature of the report is the record of the steady fall in the rate of infantile mortality. Ten years ago this rate was equal to 171 per 1,000 births. The medical officer of health (Dr. Scatterey) attributes the great improvement which has taken place in large measure to the employment of a woman health visitor, who has been assisted by voluntary helpers. Of the latter there are 6 superintendents and 30 helpers. Cards are sent each week from the Town Hall to the superintendents, giving particulars of the births notified. These particulars are distributed among the helpers, who visit the children as often as the circumstances of the case demand. Of the 648 babies visited, only 56 were bottle-fed from birth. The mortality of these was 22 per cent., and of the breast-fed children it was 10 per cent.

VACANT POOR-LAW MEDICAL APPOINTMENTS.

A. H. F. writes to ask what he is to do under the following circumstances: A medical practice seven miles away from him has been recently sold. The vendor of this practice had for many years past held two district medical appointments, and had been public vaccinator for the same two districts. All these appointments have now been given to the vendor's successor in practice notwithstanding the fact that our correspondent applied for appointment to the district in which he himself resides, and in which he is the only resident practitioner.

*. As our correspondent is the only resident in the district for which he applied to be appointed medical officer, we consider he had a prior claim to the medical appointment in question, and as no reason has been assigned for his not having been appointed, he might at once write to the Local Government Board before the appointment is confirmed, drawing attention to the application he made to the guardians for the district medical appointments and his reason for so doing.

The Services.

ROYAL ARMY MEDICAL CORPS (TERRITORIAL).

COURSE OF INSTRUCTION.

We are asked to announce that Captain Langford Lloyd, D.S.O., R.A.M.C., will commence an afternoon class of instruction for medical officers on Monday, April 19th, at 4.30 p.m. The course will extend over about six weeks, and at the first meeting the days and hour will be fixed upon. It will be held at 51, Calthorpe Street, W.C., and will be open to medical officers of both the First and Second London Divisions, and will be specially adapted for those who are about to present themselves for examination for promotion.

SOUTH MIDLAND DIVISION.

A review of the local Territorial units of the South Midland Division was held by General Sir Ian Hamilton, K.C.B., on Saturday, April 3rd. About 5,000 officers and men took part in the march past, the column being about 24 miles in length. The following units of the Royal Army Medical Corps took part in the proceedings: First South Midland Mounted Brigade Field Ambulance, commanded by Captain W. H. Stephen, 2 officers, and 100 men; Third South Midland Field Ambulance, commanded by Major A. R. Badger, 7 officers, and 100 men; Second South Midland Field Ambulance, commanded by Lieutenant-Colonel C. T. Griffiths, 6 officers, and 100 men; First Southern General Hospital, commanded by Major J. E. H. Sawyer, 25 men.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.

The offices of the British Medical Association and of the British Medical Journal are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESSES.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Atiology, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National):—

2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2630, Gerrard, BRITISH MEDICAL ASSOCIATION.

2634, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

I.R.C.S.E. asks for experience of the Wolf motor bicycle (Wearwell Company).

ANSWERS.

STATISTICAL METHODS.

G. AUSTRALIS.—The most recent and best small book on statistical methods and their application to biology and medicine is *Frequency Curves and Correlation*, by W. Palin Elderton (London: Leyton Bros.), price 7s. 6d. Our correspondent might also consult the paper on Correlation by Mr. G. U. Yule published in the *Journal of the Royal Statistical Society* about 1900. Elementary proofs relating to probable errors and correlation will be found in the various volumes of *Biometrika*, i to vi, as well as a great number of tables useful in calculating which are not available elsewhere.

BOOKS FOR THE M.D.LOND. AND M.R.C.P.

P. C.—The following works on the subjects indicated might answer our correspondent's requirements:—For the M.D. (Medicine): Osler's *Principles and Practice of Medicine*. Sixth edition. (London: S. Appleton. 1905. 21s.) Frederiek Taylor's *Manual of the Practice of Medicine*. Eighth edition. (London: J. and A. Churchill. 1908. 16s.) Rolleston's *Diseases of the Liver, Gall Bladder, and Bile Ducts*. (London: W. B. Saunders and Co. 1905. 25s.) Goodall and Washburn's *Manual of Infectious Diseases*. Second edition. (London: H. K. Lewis. 1903. 14s.) (History of Medicine): Withington's *Medical History from the Earliest Times*. (London: Scientific Press. 1894. 12s. 6d.) (Pathology): Hewlett's *Pathology, General and Special*. Second edition. (London: J. and A. Churchill. 1907. 10s. 6d.) For the M.R.C.P.: Celsus should be read, but beyond this there is no special book.

LETTERS, NOTES, ETC.

SOUTHWOLD LIFE CASE.

THE following additional subscription has been received towards this fund, which is being raised to help Drs. Munlock and Tripp to defray the heavy damages and costs (amounting to £1,005) in the recent action which they were called upon to defend:

Dr. Kirby, Cairo £ s. d.
... .. 2 2 0

Three subscriptions have also been received from laymen, one for £5 5s., another for £5, and a third for £1 s.

Cheques should be made payable to Dr. H. P. Helsham, Beccles, or to Dr. W. Tyson, The Beeches, Lowestoft.

TAX ON NOSTRUM ADVERTISEMENTS.

M.O.H. writes: I would suggest to the Chancellor of the Exchequer a tax of 25 per cent. on the cost of all newspaper advertisements of nostrums purporting to cure or prevent any kind of disease. I have roughly worked out

that this would bring in £250,000 a year, and would be easily collected, as the newspapers would charge the advertiser for the tax and forward the amount to the Exchequer. Local authorities might be allowed to issue a stamp to affix to posters of similar advertisements. Possibly 1d. per sq. ft. would bring in enough money to pay for the proper treatment of the eyes and teeth of school children.

THE DEVELOPMENT OF THE PARASITE OF ORIENTAL SORE.

CAPTAIN W. S. PATTON, I.M.S. (Stoke St. Gregory, Taunton), writes: In the BRITISH MEDICAL JOURNAL of April 3rd, which reached me this morning, I note that Professor Minchin draws attention to Dr. Row's successful cultivation of the parasite of oriental sore, which has already been mentioned in the medical profession in this JOURNAL, March 20th, p. 746. Professor Minchin states in concluding his note that he believes "this is the first time that the parasites of oriental sore have been successfully cultivated up to the flagellate stage"; this is, however, not true. If Professor Minchin will refer to the *C. R. de l'Académie de Sciences*, Paris, tome cxi, April 15th, 1908, p. 482, he will find a paper by M. Ch. Nicolle entitled, *Culture du Parasite du Bouton d'Orient*, where he can read that this, or a very similar parasite, was cultivated a year ago by Nicolle from 3 cases of oriental sore contracted at Tebessa, Algiers. A summary of this paper was published in the *Bulletin of the Pasteur Institute*, No. 9, May 15th, 1908, by Professor Mesnil. Nicolle states he cultivated the parasites on a medium prepared in the following simple way: "Gélose 14 grain, sel marin 6, eau 9,000, reparti dans des tubes et stérilisé, on ajout 1/2 sang de lapin." Professor Minchin suggests that, as Dr. Row failed to obtain any development in sodium citrate, it indicates that their mode of transmission and development is also different. I presume that Professor Minchin here indicates that the natural development of this parasite is not likely to take place in a blood-sucking insect whose digestive juices are acid. I am assuming that Dr. Row used a slightly acid sodium citrate solution. This statement of Professor Minchin with regard to the natural development of the parasite is hardly justified from the limited number of experiments carried out by Dr. Row. It is quite obvious that the parasite of oriental sore must have a flagellate stage, but what we want to know is not so much whether it will develop in one particular kind of medium or another, but in what particular blood-sucking insect it takes place. In a recent paper (*Lancet*, January 30th, 1909) I pointed out that these cultural experiments are undoubtedly interesting, but they will not help us in discovering how these parasites are transmitted in nature. This can only be accomplished by carrying out a number of feeding experiments with suitable blood-sucking insects.

FOREIGN DRUGS.

SCOPARIUS writes: Is it not time that the fashion for it is, in the majority of cases, little more than the fashion of prescribing: synthetical remedies chiefly manufactured abroad gave place to a more extended use of wholesome home-grown and home-manufactured drugs? During the past twenty-five years I have carefully tried both, and have largely given up using the former; and I find that by using British drugs my patients do just as well if not better, the saving in the drug account being as much as 50 per cent. in some years.

PRIZE FOR ORTHOPAEDIC SURGERY.

THE second competition for the Umberto I Prize was officially declared open on January 1st. The prize, which is of the value of £140, will be awarded in accordance with the decision of the provincial council of Bologna, for the best work or the most useful invention in the province of orthopaedic surgery. Foreigners as well as Italians may compete. Intimation of intention of entering should be sent to the President of the Rizzoli Orthopaedic Institute at Bologna. The competition will close on December 1st. Three copies of printed or manuscript works, either unpublished or published within the five years preceding the date of closure of the competition, should be sent. Apparatus or instruments should be accompanied by explanatory notes subject to the same conditions. The notes may be written in Italian, French, German, or English. No works which have previously been awarded a prize will be admitted.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	---	---	0 4 0
Each additional line	---	---	0 6 6
A whole column	---	---	2 13 4
A page	---	---	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a remittance.

S.R.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

An Address

ON

DYSMENORRHOEA.

DELIVERED AT A MEETING OF THE BATH AND BRISTOL
BRANCH OF THE BRITISH MEDICAL ASSOCIATION.BY G. ERNEST HERMAN, M.B., F.R.C.P.,
CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

I HAVE to make some sort of apology for offering to speak on this subject to-night, because I have so often put my opinions about it before the medical profession in my books, in the *Transactions* of the Obstetrical Society of London, and in the medical journals. I wish this evening to say more clearly and positively what I have already stated in print, and as emphatically to state my dissent from what is taught in many textbooks.

The teaching current in America and that of many books in this country is that dysmenorrhoea is a symptom which may be produced by many different causes, and that the first step towards its treatment is to find out its cause. In my work on *Diseases of Women* I have described genuine dysmenorrhoea, yet must plead guilty to having yielded to current opinion, and described more than one kind of dysmenorrhoea. Increased experience, and reflection upon experience, lead me to think that in this I was wrong. Matthews Duncan states at the beginning of his lecture on dysmenorrhoea that there are two forms—the inflammatory and the spasmodic. But in the rest of his lecture he describes only one, *dysmenorrhoea spasmodica*. In conversation I have heard him say that there was but one true dysmenorrhoea, and this proposition is implied throughout his lecture. Of all men who ever wrote upon gynaecology, Matthews Duncan was the most exact in the use of language, and the most learned in the literature of his subject. The last edition of his *Clinical Lectures on the Diseases of Women* was published in 1889. Since then surgery has marvellously advanced, so that the considerations upon which the family doctor has to base his advice for or against operative treatment are very different now from what they were when Duncan practised. But this is almost the only thing in which these wonderful lectures are unsuitable as a guide to the practitioner to-day. They contain a store of accurate pathological and clinical information that is to be found in no other book that up to then had been published. It is remarkable that this great work should have so little influenced American practice. In that great and progressive country the newest methods of cutting and stitching seem to be thought so important that no one who wishes to be thought up to date can stop to read a book twenty years old. Hence we have a report of an operation by the surgeon-in-chief of a gynaecological clinic in one of the largest and oldest cities of America, describing how he opened the peritoneal cavity, and found no disease within it, he being in complete and amazing ignorance of pelvic cellulitis, although he might have found in Duncan's twenty-year-old lectures an accurate description of its phenomena. And quite recently I opened a book on medical gynaecology by an American, who seemed as ignorant about dysmenorrhoea as the surgeon was concerning pelvic cellulitis.

This is a digression. The first thing I wish to say is that dysmenorrhoea is a disease, and not a symptom.

About one third of all women menstruate without pain. These happy beings also have, as a rule, good appetites; they sleep soundly, and they are not easily tired; they have healthy nervous systems.

There is before and during menstruation some increase in vascular tension and rise of temperature. In patients who are ill or weak, the effect of this is to reduce the strength of the nervous system, and to make them more sensitive to pain; and hence such patients have pain before and during menstruation. In most women this pain is only slight; they feel uncomfortable, but there is nothing in their appearance or behaviour to announce to their friends or acquaintances that menstruation is present or imminent. The degree to which the patient is incapacitated by this pelvic aching depends upon the strength of her nervous system—that is, upon her power of resisting

pain. If she is neurasthenic, she may feel so ill that she may wish to keep in bed. Whether she does so or not will depend upon circumstances. One patient of mine, a married woman with children, told me that she had always kept in bed for a day or two each month ever since menstruation began. I happened to know that before her marriage she had been a hospital nurse, and I asked whether she went to bed each month while she was nursing in the hospital. She said: "No; I had to keep up." I have no doubt there are numbers of young women earning their living in various ways—servants, shopgirls, barmaids, actresses, teachers—who, if circumstances permitted, would be glad to lie down; but they prefer to put up with the pelvic aching rather than run a risk of losing their situations. In these patients there is nothing the matter with any pelvic organ. The case is that the nervous system is weak, so weak that its power of resistance to pain breaks down under the stress of menstruation. One writer applies to cases of this kind the term "neurasthenic dysmenorrhoea." The objection to this term is that it suggests that the uterus is at fault, and that therefore the uterus should be treated. In these cases there is nothing the matter with any pelvic organ; the uterus is only fulfilling a physiological function, and no good, but possibly much harm, can come from meddling with it.

In nearly every local disease that causes pain this pain is worse about the time when menstruation begins. The dragging of prolapse, the sacral aching caused by a retroverted uterus, the pain of salpingo-oophoritis and pelvic peritonitis are all worse at this time. But the pain is not the acute spasms of dysmenorrhoea; it is the usual pain of prolapse, or retroversion, or pelvic peritonitis, as the case may be, rather worse than usual. We may explain it by saying that it is aggravated by the pelvic congestion which precedes menstruation, or that it is more felt, owing to the weakened state of the patient's nervous system. We may, it is true, meet with cases of painful pelvic disease who mention first, as the reason why they seek advice, the menstrual pain they suffer; but further inquiry will elicit that the menstrual pain is only one incident, and that there is, or has been, similar pain at other times also. It is true, also, that local disease confers no immunity against genuine dysmenorrhoea, and a patient may have real dysmenorrhoea as well as pain in the pelvis caused by a local morbid condition.

In many nervous diseases the symptoms are worse when menstruation is approaching or beginning. This is often the case in neuralgia, epilepsy, chorea, mania, migraine, etc. But aggravation of nervous symptoms by temporary lessening of the resisting power of the nervous system is not dysmenorrhoea. In a few cases some nervous disease may be complicated with actual dysmenorrhoea; but it is an accidental complication only. Such terms as "menstrual epilepsy," which imply dependence of disease on menstruation, have an ill effect, because they have led both doctors and patients to think that benefit in these diseases will follow the stoppage of menstruation. This is not the case. No benefit, in these diseases, follows removal of the ovaries.

Now I come to recant my own errors. I have written of obstructive dysmenorrhoea; but I think this would be better called by a different name. I have, like many others, written about "membranous dysmenorrhoea." The term implies that there is a resemblance, indeed an identity, between the pain caused by obstruction to the exit of the menstrual flow, or by the presence of a membrane, and the very severe pain of dysmenorrhoea.

If "dysmenorrhoea" be restricted to what I think should be its proper meaning, and is used to denote morbidly painful uterine contractions accompanying menstruation, then there is no such thing as obstructive dysmenorrhoea. There is sometimes obstruction to the exit of menstrual fluid, but if pain is caused by such obstruction it is only slight. I have seen more than once a vaginal portion with a circular external os so small that it would not admit the ordinary uterine sound, but the patient's menstruation was painless. After amputation of the cervix, the opening into the uterine cavity is sometimes contracted by scar tissue but menstrual pain, if present, is not severe. In congenital atresia of the genital passage leading to retention of menstrual fluid, although the history usually is of slight monthly attacks of pain, yet cases occur in which with

retention of menses lasting over years, and forming a tumour palpable by the abdomen, there has been no pain. I am not acquainted with any such case in which the pain has been anything like that of dysmenorrhoea. Therefore, I think these cases are better spoken of in language that denotes the anatomical condition present—namely, stenosis or atresia.

"*Membranous dysmenorrhoea*" is understood to mean pain caused by the menstrual decidua being shed in one or more pieces instead of in a pulp. I dare say most of us here are or have been under the impression that this is a disease both rare and painful. But I doubt its being either rare or painful. Those of us who have thought it so have formed that judgement from the observations of a few sensitive, intelligent, observant, and reflective patients. The patients have come to us because, being sensitive, they had monthly pain; because they had pain, being intelligent they examined their discharges; being observant, they perceived in them solid lumps; and being reflective, it occurred to them that these solid lumps might be the cause of the pain; and so they preserved the membranes and brought them to us. But those who have instructed nurses to thoroughly examine what passes from every menstruating woman have found that bits of membrane are passed far more frequently than is supposed. Scanzoni found them in two-thirds of women; Sir John Williams in three-fourths. Such a frequency suggests doubt as to whether the passage of membrane should be regarded as disease. The pain when membranes are passed is seldom great. When a miscarriage takes place the substance passed is bigger than the menstrual decidua; but, as every one knows, a doctor is not usually summoned to a woman who is aborting on account of the severity of the pain. Further, I have taken into hospital patients who came for treatment on account of menstrual pain, and who produced membranes which they had passed; and in the hospital, without local treatment, but only the benefit of rest, sound sleep, and good food, these patients menstruated, passed membranes as usual, but without pain. I draw the conclusion that most patients who pass membranes with pain, suffer pain not because membranes are passed, but because their nervous systems are weak; in other words, that pain in passing membranes is not dysmenorrhoea, but a manifestation of neurasthenia.

The disease to which, in my opinion, the term "*dysmenorrhoea*" should be restricted consists in painful uterine contractions which accompany menstruation. The pain has distinctive characters. Not all cases are alike in severity, but in the worst cases the pain is far more severe than any other kind of pain felt in the pelvic region without physical signs of disease. Acute peritonitis may cause severe pain. But in peritonitis there are physical signs—rise of temperature and pulse, and fixation of the uterus. In the worst cases of dysmenorrhoea the patient writhes, perspires, vomits, sometimes faints with the severity of the pain. The pain is not relieved by lying down. In pain due to inflammation or congestion of dependent parts of the body the patient feels better when she is lying down. But the pain of dysmenorrhoea not only is not relieved by recumbency, but if, as often is the case, in obedience to maternal advice the patient keeps in bed, she cannot lie still, she rolls, wriggles, and writhes with pain. Another feature of the pain, besides its great severity, is its short duration. The discomfort produced by the monthly congestion of the pelvic organs begins some days, sometimes even a week or more, before the flow appears, and it lasts until the flow is nearly or quite over. There are remissions in its severity, and the duration of the attacks and remissions is, usually two or three hours. The spasmodic pain of dysmenorrhoea only lasts a few hours, seldom longer than twenty-four hours, and the duration of each spasm of pain is commonly only a minute or two, about as long as a labour pain. It generally begins with the flow.

I know absolutely nothing of the cause or causes of dysmenorrhoea. I know of no criteria from which to predict that a particular girl who is approaching puberty when she menstruates will have acute spasmodic pain; nor is anything known to me from which I can predict that a young woman who has menstruated for a few years without pain will suddenly come to suffer severely when this function returns. As I am unable to predict that pain will occur, it follows that I am equally unable to

prevent it. Antelexion, smallness or conical shape of the vaginal portion, and smallness of the os externum are conditions regarded as morbid by certain practitioners. People who study disease as it is seen in the dead body never find any morbid effects from these conditions. If they were really malformations capable of setting up trouble in connexion with menstruation, that trouble would always date from the beginning of the function. The view that dysmenorrhoea depends upon a malformation is to me inconsistent with the clinical experience that in about one-third of the cases the pain suddenly begins after years of painless menstruation.

There are those who say that dysmenorrhoea is usually due to endometritis. This kind of endometritis is like the so-called malformations—a disease unknown to those who examine dead bodies. I do not believe that, except very rarely as a result of accidental infection or a new growth, endometritis exists in virgins. As in two-thirds of the cases the pain dates from the time of the first menstruation, the endometritic theory postulates that endometritis occurs not only in virgins but in girls at puberty. Of this there is no evidence.

There is a disease in which we know at least the immediate cause of dysmenorrhoea. I refer to cases in which the uterus contains a small fibroid, and the uterine contractions are forcing it, first out of the uterine wall into the uterine cavity, and then through the cervical canal into the vagina. In these cases the pain is often severe and of the dysmenorrhoeal spasmodic character. These cases, nevertheless, do not invalidate my statement as to our ignorance of the causes of dysmenorrhoea; for we know not why fibroids grow; we can neither predict nor prevent their growth, and if we find a uterus enlarged by what we take to be a small fibroid, which is not at present giving trouble, we cannot tell whether it will grow larger or not, whether it will be expelled into the vagina or not.

Some writers, who have not learned to recognize the disease that I am speaking of, begin their advice as to the treatment of pain with menstruation by telling the pupil that he "should improve the general health." This is a platitude that applies to every patient, man, woman, or child. The writer might as well go on to say that the patient should have enough to eat and sufficient clothing. I know no condition of the general health that has anything to do with the production of dysmenorrhoea. Like many other nervous symptoms, it is apt to occur in young women with highly-developed sensitive nervous systems; but I know of no signs distinctive enough to enable us to predict that a particular girl, when she menstruates, will do so with pain. When dysmenorrhoea arises after years of painless menstruation patients often have an explanation of their own for it—such, for instance, as some mental or physical shock or strain. There are few patients who, if they are invited to think of something that may have made them ill, and will search their memories hard enough, cannot find some occurrence in their lives which will suit. But I have not been able to elicit any incident which has preceded dysmenorrhoea as frequently as anything which was really a cause of the disease should have done.

With dysmenorrhoea there is often indifference or repugnance to sexual intercourse. This may be so although intercourse is neither difficult nor painful, and such patients are generally sterile. In such cases cure of the dysmenorrhoea will often at once produce sexual desire and enjoyment, sometimes soon followed by pregnancy. I cannot say to what proportion of cases the above statements apply, because the matter cannot be inquired into as a matter of routine, but I have been told of it often enough to make me sure that it is more than a coincidence. In one case the patient's dysmenorrhoea was cured at a time when her husband was abroad, and the patient told me that she looked forward to her husband's return with feelings different from any that she had ever before experienced.

This close association of dysmenorrhoea with imperfection of the reproductive function seems to me to mark this disease as one *sui generis*. There is no such association with any other kind of menstrual pain, or with any other morbid condition of the pelvic organs that I know of.

I have already said that one of the most distinctive

features of dysmenorrhoea, as contrasted with pains of other kinds made worse by menstruation, is the extreme severity of the pain. This terrible pain reduces the pain-resisting power of the nervous system. The consequence is that reflected pain is felt over the skin supplied with sensory nerves from the eleventh dorsal to the second lumbar segments of the spinal cord. Touch the skin over this region while a patient with dysmenorrhoea is menstruating and she winces at once. When dysmenorrhoea has existed for years, the result of the oft-repeated periodical reduction of the strength of the patient's nervous system is that this reflected pain comes to last longer and longer, until at length, after many years, it may be practically continuous. I have also mentioned vomiting as an effect of the spasms of pain. At first the vomiting only occurs when the patient is in pain; but as years go by the vomiting, like the pain, lasts each month longer and longer; and I have known and published elsewhere the details of a case in which a patient died exhausted by incessant vomiting and inability to retain food, for which vomiting no cause was discovered except dysmenorrhoea; but I must admit that no *post-mortem* examination was made.

Dysmenorrhoea has no tendency to spontaneous cure. The only cure other than by medical treatment is child-bearing. Although the co-ordination of the menstrual and sexual function are both imperfect, and consequently the meeting *in utero* of the germ cell and the sperm cell is not helped as it should be; yet, nevertheless, the germ cell and the sperm cell may meet, and pregnancy occur; and then, in most such cases, dysmenorrhoea is cured.

One cannot help having some theory of the disease. My own is that dysmenorrhoea exists because the centre in the spinal cord, or in the sympathetic system which should regulate the movements of the genital canal, is imperfectly developed. The vagina, uterus, and Fallopian tubes are muscular organs, like the intestine. During labour there is contraction of the uterus to expel the child. There are morbid kinds of uterine contraction which I need not here dwell upon. During the sexual orgasm, I believe there is a co-ordinated muscular action of the Fallopian tubes, uterus, and vagina, having for its object to help the ovum into the uterus, and also the spermatozoa into the uterus. In a normal painless menstruation there are contractions of the body of the uterus, and dilatation of the cervix, so that the menstrual flow is expelled without pain or difficulty. My theory is that in dysmenorrhoea this natural dilatation of the cervix is absent, and, in consequence, the contractions of the uterine body are morbidly violent and painful. The only physical sign that I think I have observed in cases of dysmenorrhoea is difficulty in dilating the cervix. I say "I think" because I have no way of measuring the amount of force used in passing each dilator; and my impression may not be correct. But every now and then one meets with a case in which the nature of the monthly pain is not clear, or a patient who has little or no monthly pain, but is sterile, and wishes to leave nothing undone that can possibly favour pregnancy. In such cases I have advised and performed dilatation of the cervix as a possible, rather than a probable, source of benefit. My experience has led me to expect that when the cervix dilates slowly and with difficulty the dilatation will cure the dysmenorrhoea; but that when one dilator after another slips in without more than trifling resistance, the object of treatment will probably not be attained. The disease is not from obstruction. Although I have conjectured that the pain is because physiological dilatation or relaxation, if that word be preferred, does not take place, yet the canal in its undilated, unrelaxed state is quite big enough to let the patient bleed to death through it. In fact, young virgins have bled to death through the cervical canal. Nobody has ever yet seen retention of blood in the uterine cavity as the result of dysmenorrhoea, even when the vaginal portion is supposed to be infantile, or long, or conical.

As to Treatment.—I shall not discuss the palliative treatment—that is, the relief of pain when it has arrived. It resolves itself into the local application of heat and swallowing of coal-tar analgesics. The cure is to prevent the arrival of the pain. Every case of dysmenorrhoea can be cured. The unfailing cure is to stop menstruation. The question is whether, in a particular case, this remedy

is not worse than the disease. Fortunately it is seldom that this extreme measure is required.

The first and simplest treatment is by a drug. There is one drug that will cure some cases of dysmenorrhoea. That drug is *guaiaicum*. I prescribe 10 grains of *guaiaicum* resin three times a day, begun a week before menstruation is expected, and continued until the time at which the pain usually occurs is past. It may be given in a mixture either with milk, as in the *British Pharmacopoeia*; or with gum tragacanth, as in the London Hospital pharmacopoeia; or mixed with malt extract; or in a cachet. In some cases this drug will prevent the pain from coming on, or lessen its severity when it does come. I cannot say what proportion of cases it cures, for it is so difficult to follow up the histories of this class of patient; but I have seen instances enough to make me sure that the relation between the drug and the disappearance of pain is more than coincidence. A patient consulted me in January, 1902, being then unmarried and aged 21. She had suffered from dysmenorrhoea for two years. The pain was paroxysmal, it was not relieved by lying down, and it was so severe as to make her vomit. I did not examine her, but prescribed *guaiaicum*. A few days ago she told me that since taking the medicine she had had no more of the old monthly pain. She had been now married three years, but was sterile.

If drug treatment fails, the next thing is to dilate the cervix. This is best done with metal bougies, and, when the patient is young and unmarried, under anaesthesia. As a rule, the passage of bougies up to No. 12 on the catheter scale is enough to cure the patient, but, if the patient is anaesthetized, it can be carried a little further without harm, and possibly greater certainty of cure. In the days of my professional youth it was the general practice to cut through the vaginal portion with scissors, in one or more places, and this was often successful. But dilatation is, I think, more certain, for it dilates the whole canal, and not the os externum only. If the os externum is very small and circular, I should still advise its division, to avoid, in case of subsequent pregnancy, slowness of the first stage of labour.

Most cases of dysmenorrhoea are cured by dilatation. The relief may last throughout the whole subsequent duration of the menstrual function. It may last only for a few months, and then a repetition of the dilatation may lead again to relief, this time probably of longer duration. I know no more of the cause of the relapse than of the original cause of the disease. If the patient is married, the dilatation favours pregnancy.

The natural cure for the disease is pregnancy. This involves the utmost possible dilatation of the cervix, the dilator being the baby's head. But this cure is not available for every patient.

Unfortunately, it must be admitted that there are cases in which all treatment fails, and the pain is very severe. I have already pointed out how each monthly storm of pain breaks down the resistance of the nervous system more and more so that the reflected pain comes to be more widely and severely felt, and lasts longer each month, until the patient becomes an invalid for many days each month. If when the patient is reduced to this condition she yet has no prospect of marriage, and is willing to renounce the potentiality of maternity, I think she is entitled, if she chooses, to be cured by having menstruation stopped—that is, by having her ovaries removed. Special circumstances may induce us to listen to this request from a young woman. If she has no relatives who can support her, if she cannot keep any situation because of the illness which each month prostrates her, and all other treatment has failed, what is to be done?

This brings me to the reason why the limitation of the term "*dysmenorrhoea*" is not a mere verbal quibble or pedantic futility. To so limit the word is to recognize that genuine dysmenorrhoea is a different thing from disease the symptoms of which are worse when the patient menstruates. In cases, for instance, such as what one writer calls "neurasthenic dysmenorrhoea," which means a patient with neurasthenia who feels worse about the time of menstruation, after stopping menstruation by removing the ovaries, the patient is no better, for menstruation is not the only thing that makes such patients worse; and very likely the disappointment of the relief she hoped for, and the sense of the value of

the potentialities she had lost, will make her worse. So with so-called menstrual epilepsy, neuralgia, etc., taking out the ovaries only removes an occasional exciting cause; it does not cure the patient, and may make her worse. But if the primary original disease was dysmenorrhoea, and the added neurasthenia has been produced by the severity of the pain with menstruation, the patient will be cured if menstruation is stopped. Before advising so grave a measure as oophorectomy the great thing is to be sure that the pain and the prostration spring from menstruation and from nothing else. The practitioner will be in an unenviable position who hastily proposes removal of the ovaries for a few attacks of colic due to flatulence or constipation. But careful observation ought to prevent such a mistake.

ON THE IMPORTANCE OF PAIN AND HAEMORRHAGE AS SYMPTOMS OF EXTRAUTERINE GESTATION.*

By THOMAS WATTS EDEN, M.D. EDIN.,

F.R.C.P. LOND., F.R.C.S. EDIN.,

SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; OBSTETRIC
PHYSICIAN TO CHARING CROSS HOSPITAL; PHYSICIAN TO
QUEEN CHARLOTTE'S LYING-IN HOSPITAL.

Few of the conditions which come under the notice of the gynaecological surgeon are of greater interest in diagnosis than extrauterine gestation. Occasionally cases occur which present features so striking and so characteristic that their nature is readily recognized. But this is not always the case, for the clinical features may be so complex as to puzzle the most experienced observers. And not only are the clinical features complex, they are also subject to extraordinary variation in character and severity, so that it may be difficult to believe that the same pathological condition has given rise to them all. The explanation of these difficulties lies in the fact that the symptoms associated with extrauterine gestation arise, not directly from the presence of the growing ovum in the Fallopian tube, but from certain secondary lesions, either traumatic or inflammatory, which supervene.

These secondary lesions may be briefly enumerated as follows:

1. Intraperitoneal flooding from tubal abortion or rupture.
2. Intratubal bleeding, leading to acute distension of the tube, the abdominal ostium being sealed.
3. Slowly progressive or recurrent haemorrhage, leading to the formation of encysted collections of blood—for example, *pelvic haematoma*, in the broad ligament; *pelvic haematocoele*, in the pouch of Douglas; *peritubal haematocoele*, around the abdominal end of the tube.
4. Infection of the gravid tube, or of an encysted collection of blood, leading to suppuration.

Until one or other of these secondary lesions is produced, extrauterine pregnancy gives rise to no more local or general disturbance than does an early pregnancy in the uterus. An important symptom associated with this phase—namely, a brief period of amenorrhoea—is a most useful aid in diagnosis, but it is by no means always present. When a healthy adult woman, who is usually regular, goes for two or three weeks over the expected date of her period, there is a strong presumption of pregnancy, but at this time there is nothing to indicate whether pregnancy is uterine or extrauterine. In the latter case, however, amenorrhoea is of very brief duration, seldom more than seven or eight weeks, and then gives place to haemorrhage. In something like 30 per cent. of the cases which have come under my own observation there has been no amenorrhoea at all, and I am satisfied that while this symptom forms a useful positive indication, no importance whatever can be attached to its absence. As it is quite unusual for an extrauterine gestation to continue undisturbed beyond the end of the second month, there is consequently no time for the appearance of other general symptoms of pregnancy. But occasionally morning sickness and early breast changes may be met with. When the course of the gestation becomes interrupted by any of the occurrences mentioned above, the clinical features

undergo rapid transformation, and symptoms appear which we are accustomed to regard as those of extrauterine pregnancy; they are, however, in reality those which result from the interruption of the pregnancy by injury to the developing ovum or to its containing sac.

These symptoms, which it is clear ought to be regarded as *secondary symptoms*, are subject to great variation in their character and intensity in correspondence with the nature of the lesion which has given rise to them. The occurrence which is the simplest and the most easily recognized is *intraperitoneal flooding*; the symptoms which attend it are uniform and characteristic, and when a clinical history of amenorrhoea can be obtained, and a careful pelvic examination made, mistakes are hardly possible. Perforation of a hollow viscus, such as the stomach, duodenum, or gall bladder, is the only condition for which it is at all likely to be mistaken, even under circumstances unfavourable for diagnosis. The following case, which is typical of its class, illustrates the remarkable simplicity of the diagnostic problem.

CASE I.

On May 6th, 1904, I was asked by Dr. Hooper, of Sutton, to come down at once to see a case which he believed to be one of ruptured extrauterine pregnancy. The patient was a tripara, 32 years of age, her last confinement having taken place fifteen months previously. In March, 1904, she had a regular period; in April she went six days over her time, when slight bleeding occurred and continued for eight days; after an interruption of twelve hours, it recurred, and continued unchanged up to May 6th. Owing to the haemorrhage, she was kept to bed from May 2nd onwards, and treated with douches and small doses of ergot. On the afternoon of May 6th, while using the douche, she was seized with sudden severe abdominal pain, accompanied with an urgent desire to relieve the bowels. She remained straining at stool and in great pain for some time, and then fainted. Dr. Hooper, when summoned two hours later, at once recognized the signs of severe internal haemorrhage, and I saw her about five hours after the onset of the acute abdominal pain. She had vomited several times, but her general condition had then begun to improve; the face was pale and drawn, the pulse was very small and its rate about 100, the temperature was subnormal, and the skin cold and rather moist. She complained of severe epigastric pain, but was not restless. The abdomen was not distended, but there was marked tenderness over the hypogastric and left iliac regions, which were also dull on percussion. On vaginal examination, a soft swelling was found in the pouch of Douglas, and a firmer, better-defined mass to the left side of the uterus. We had no difficulty in recognizing the case as one of left tubal pregnancy with intraperitoneal flooding, probably due to rupture. It was pretty certain that the bleeding had for the time ceased, and we therefore spent some hours in restorative measures, and operated the next morning, when her general condition had greatly improved. About 30 oz. of fluid and clotted blood were removed from the peritoneal cavity, and in the isthmial portion of the left tube was found a rupture with a small cuboid-shaped mole attached to it. An illustration of this specimen appears in the author's text-book of *Midwifery* (Fig. 60). The tube and ovary were removed and the patient made a good recovery, and has since then given birth to another child.

It is obvious that the diagnosis of a case of this class is a comparatively simple matter, but the symptoms which preceded and attended the rupture of the tube are of great interest and importance. In the first place, it is to be observed that slight haemorrhage, following a brief period of amenorrhoea, had been going on for three weeks before the tube ruptured. Haemorrhage from the uterus is a secondary symptom of extrauterine gestation which is constantly present. If no period of amenorrhoea has occurred it forms the initial symptom, if there has been amenorrhoea it succeeds it. In the great majority of cases it is the earliest indication of anything wrong, but as the same thing frequently occurs from disturbance of a uterine pregnancy, little importance is usually attached to its appearance either by the patient or her doctor. The haemorrhage is slight or moderate in degree, sometimes continuous, sometimes irregular; and, as the late Dr. Cullingworth pointed out, it is usually dark, thick, and syrupy in appearance. It may continue for several weeks if the patient is not relieved by operation. The bleeding is no doubt due to separation and discharge of the uterine decidua, sometimes complete, more often in fragments; but in the majority of cases the pieces of membrane do not attract attention, and are not detected by the medical attendant.

This attempt on the part of the uterus to throw off its decidua when the tubal ovum has been damaged is a most interesting phenomenon. Some reflex mechanism is no

* Read at a meeting of the Richmond Division of the British Medical Association, January 11th, 1909.

doubt initiated which excites uterine contraction sufficiently powerful to detach portions of the membrane from the uterine wall, and so give rise to haemorrhage, which continues until the whole of the decidua has been expelled. It is, however, possible that at the commencement some of the blood which escapes from the uterus may have made its way there from the gravid tube through the interstitial portion. In cases submitted to operation, the haemorrhage always ceases in a few days after the removal of the tube, and I know of no instances in which portions of decidua have been retained, giving rise to persistent bleeding, as is so often the case in uterine abortion.

It is interesting to note that the effects produced by the rapid effusion of a large quantity of blood into the peritoneal cavity were, in the order of their occurrence: (a) acute abdominal pain; (b) fainting and the constitutional signs of haemorrhage; (c) shock, attended by vomiting, and lasting for several hours. The quantity of effused blood was estimated at 30 oz., and the bleeding probably ceased spontaneously when the patient fainted. After an interval of eighteen hours, very marked improvement in her general condition had taken place. This improvement is an important point, and of itself serves to distinguish such cases from perforation of the stomach or intestine, in which the peritoneum is continuously flooded with highly irritant fluids, and the patient's general condition passes rapidly from bad to worse.

The sudden attack of intense abdominal pain in this case was produced not by rupture of the tube, but by the rapid inundation of the peritoneum with effused blood. Pain, equally severe, may result from sudden free bleeding in tubal abortion—that is, haemorrhage through the patent abdominal ostium—and there is no doubt that it is due to the intense peritoneal irritation caused by blood being brought into contact with a large area of this membrane. The actual laceration of tissue caused by the rupture is probably only an inconsiderable factor in the production of pain. The subsequent course of events—fainting, the development of constitutional signs of haemorrhage, and then the gradual recovery from shock—revealed the causation of the attack, but, as we shall see, the subsequent symptoms are not always of the same illuminating character.

No matter what may be the nature of the secondary lesions occurring in a case of tubal pregnancy, these two symptoms are common to them all—namely, uterine haemorrhage and pain. The pain which is met with has certain characteristic features which deserve attention. It is almost always sudden in onset, and usually spontaneous, although muscular effort, such as lifting something heavy or the act of defaecation, may appear to excite it; it is always severe, and often of the most intense character; it affects at first the whole abdomen, but later may become localized; it is frequently attended with vomiting and other signs of shock, sometimes with faintness or actual syncope; after lasting acutely for several hours it subsides, and thereafter may recur at varying intervals of a few days or a week, until several attacks have been sustained; sometimes continuous pain without exacerbation follows the first attack. The initial attack of pain is almost always due to haemorrhage; the subsequent attacks have a more complex origin, and this I shall endeavour to illustrate by relating a few cases. But pain bearing the broad characteristics above described is a constant symptom of extrauterine gestation, and I regard it as the most reliable indication of the existence of this condition.

In cases not immediately submitted to operation recurrent attacks of intense pain may occur from repeated intraperitoneal haemorrhages, as the following case shows:

CASE II.

This patient was sent to me at the Chelsea Hospital for Women by Dr. Maguire, of Kew, on October 20th, 1904. She was a woman 27 years of age; she had had no children, but a miscarriage had occurred in the previous February. Menstruation had been regular since this occurrence and during the course of an ordinary period which began at the expected time, on October 6th, she was seized with acute abdominal pain, which lasted with intermissions for three to four days. Then she improved, but slight uterine haemorrhage continued for eleven days, that is, till the 17th, when another similar attack of severe abdominal pain occurred.

Dr. Maguire then diagnosed extrauterine gestation, and sent

the patient into the hospital. When admitted she was complaining of great pain; she was pale and restless; her temperature was 100°, and her pulse 110; the abdomen was distended and tender. There was also slight uterine haemorrhage. Behind the cervix a soft mass could be felt, but the abdomen was too much distended to allow of a satisfactory bimanual examination being made. Having decided that it was not necessary to operate immediately, during the next two days the bowels were freely relieved by enemata, the abdominal distension subsided, and the patient's general condition improved. Three days after admission, although she had not been allowed to get up, another acute attack of abdominal pain occurred, and lasted for several hours. On October 25th I operated, and found a large quantity, estimated at 24 pints, of fluid and clotted blood lying free in the pelvic and abdominal cavities; there was no attempt at encapsulation by adhesions. Having removed this we found the left Fallopian tube dilated, and ruptured in its outer third. The damaged tube was removed, and the patient made a good recovery from the operation.

It will be seen that in this case the diagnosis was not quite so obvious as in the first case. There had been no initial period of amenorrhoea, for the patient's illness began during the course of what she regarded as a normal monthly period. Further, the prominent symptom was acute abdominal pain which lasted for three to four days with intermissions. Collapse and faintness were absent. Two similar attacks of acute pain occurred at further intervals on the eleventh and seventeenth days after the first attack. Signs of internal haemorrhage gradually developed, but at the onset of the illness they were not apparent. It is, I think, clear that in this case rupture of the tube led, not to a single profuse haemorrhage suddenly flooding the peritoneal cavity, but to a more moderate and progressive haemorrhage, which was arrested spontaneously, but recurred twice at intervals of eleven and fourteen days after the first bleeding. The total amount of blood lost was nearly double that lost in the first case, yet, owing to the slower rate of bleeding, the degree of constitutional disturbance was much less. There can be no doubt that each attack of acute pain coincided with an outbreak of fresh bleeding, and was due to the same cause—namely, peritoneal irritation.

It will be borne in mind that there was no attempt at encapsulation of the blood which had been escaping into the peritoneal cavity intermittently for three weeks. In such circumstances the pain attending the haemorrhages cannot be due to tension, but must be the reaction of the sensory nerves of the peritoneum.

Acute attacks of intense abdominal pain may, however, arise in extrauterine gestation under conditions quite different from those of Cases I and II.

CASE III.

Mrs. J., aged 50, unipara. She had had one child eight years previously, that is, in 1892, and in the second week of the puerperium a severe illness developed, which lasted for about a month. It was probably some septic complication resulting in pelvic inflammation. Since this illness she had never been well, and complained of nearly constant pelvic pain. She was quite regular up to March, 1900; the April period was missed, and about ten days later, on May 3rd, moderate haemorrhage set in, and continued for about fourteen days. On May 17th she was suddenly seized during the night with the most intense abdominal pain. So severe was the pain that she was placed under anaesthesia in order to make a satisfactory examination of her condition. The uterus was found to be retroverted, a soft swelling was detected on the left side of the uterus, and a provisional diagnosis of extrauterine gestation was made by her medical attendant, Dr. Maguire. I saw the case on the following day, and was inclined to think that the swelling on the left side was an abscess in the tube or ovary, and that the acute attacks of pain were due to escape of pus and resulting localized peritonitis. I was not as familiar then as I am now with the fact that escape of blood into the peritoneal cavity may cause pain quite as acute as the perforation of an abscess, or of a hollow viscus. At the operation we found many old and dense pelvic adhesions matting the uterus and its appendages together on either side, and isolating this part of the pelvic cavity. On separating these adhesions a few ounces of recent blood clot were found confined beneath them; the left tube was seen to be dilated, and was isolated from its attachments only with considerable difficulty. A tubal mole, the size of a goose's egg, was found among the clot, and on carefully examining the tube we came to the conclusion that the case was probably one of tubal abortion. The patient made an uninterrupted recovery.

In this case I believe that the extraordinary intensity of the pain was in great part due to the fact that the haemorrhage occurred into a confined space. The density of the pelvic adhesions quite precluded the possibility of their having been produced by the effused blood—that is, of

their being not more than twelve days old. The lower part of the pouch of Douglas, where the effused blood was found, was thus hermetically sealed, and the tension set up in it by the effusion of a few ounces of blood, while no doubt it intensified the pain, was probably of service in arresting the haemorrhage before any great amount of blood had been lost. It is obvious from this case that the amount of blood poured into the peritoneal cavity is not the only determining factor in the degree of pain produced. The absence of constitutional signs of haemorrhage was, of course, easily explained by the conditions found at the operation, but it was to their absence that I attribute my failure to correctly diagnose this case.

These three cases will serve to illustrate the symptoms which arise when *intraperitoneal* bleeding occurs in extrauterine gestation, and among these symptoms the predominance of pain and haemorrhage is so obvious that no comment upon it is necessary. But very similar symptoms may occur from intratubal haemorrhage, without any escape of blood into the peritoneal cavity at all, as will be seen from the following case:

CASE IV.

Mrs. A., 36, tripara, menstruated regularly from her last confinement in 1904 till November, 1907. The December period did not come when expected, and a week later, on December 25th, a little bleeding accompanied by a good deal of pain occurred and lasted for fourteen days. This was quite unlike her ordinary periods, which are painless and last only three or four days. After this she was fairly well for a week, when she was suddenly taken seriously ill in the street, with acute abdominal pain and faintness. When she got home she was seen by her medical attendant, Dr. Aphthor of Harrow, who found her suffering from shock, indicated by pallor, rapid breathing and rapid pulse, and complaining of abdominal pain, which was accompanied by general tenderness and some rigidity. After two or three days in the cottage hospital she improved sufficiently to return home at her own request; but she continued to suffer from severe internal pain, for which morphine was several times required, and her evening temperature was usually about 100° F. When the acute attack of pain occurred haemorrhage again set in and lasted for fourteen days. After an interval of ten days it again recurred and continued up to within a few days of her admission to the Chelsea Hospital for Women on February 21st, 1908. Her temperature was then 100.2°, and she complained of a good deal of abdominal pain and tenderness. There was no pallor, and the pulse-rate was under 100, so that it was evident there had been no serious internal bleeding. In the pouch of Douglas we found a firm elastic swelling of considerable size, which extended well over to the right side and displaced the uterus forwards and to the left of the middle line. These conditions, taken in conjunction with the history, clearly justified a diagnosis of right tubal gestation. At the operation we found, after separating some delicate omental and intestinal adhesions, that the swelling was an unruptured gravid right tube; there was no free intraperitoneal blood, but the tube, which was very thin-walled, was ruptured in separating its adhesions. The tube was removed and the patient made a good recovery.

The probable course of events in this case was that on December 12th an inconsiderable intratubal haemorrhage occurred, indicated by slight uterine loss and great pain for twenty-four hours. Fourteen days later a second and much more extensive intratubal haemorrhage occurred, leading to intense abdominal pain and shock, symptoms which we have just seen may be associated equally well with intraperitoneal bleeding. The amount of blood which can be thus effused into a sealed tube is comparatively small, consequently there were no constitutional signs of haemorrhage. As in Case III, the intensity of the pain was, no doubt, due to the effusion taking place into a confined space.

From these cases it is clear that acute and sudden abdominal pain is a characteristic feature of internal haemorrhage in extrauterine gestation.

The most frequent of all the secondary lesions which may result from extrauterine gestation is a pelvic haematocoele—that is, an encysted collection of blood in the pouch of Douglas. If bleeding is intraperitoneal, and plastic peritonitis occurs around the effused blood, resulting in the formation of a haematocoele above and around the condition is not at once relieved by operation, the distended tube, shutting it off from the general peritoneal cavity. Absorption and shrinkage take place very slowly under these circumstances, and the two symptoms which almost constantly attend pelvic haematocoele are readily explained by the internal conditions—namely, constant abdominal pain and slight to moderate fever. The pain is due in part to the presence of the

pelvic swelling, in part to the local peritonitis to which it gives rise; the fever is due in part to the local peritonitis, in part also to the passage into the circulation of the disintegration products of effused blood. The clinical history of such cases closely resembles that of the case last mentioned, the same predominant importance being associated with the pain.

CASE V.

Mrs. C., aged 40, quintipara. Her last child was born in 1892, and menstruation was regular up to October, 1907, when a regular period occurred in the first week of that month. The November period was missed, and fourteen days later fairly free haemorrhage set in and continued for a fortnight, when a large clot was passed. She went about all this time, but suffered some pain in the abdomen and breasts. The bleeding ceased after some fragments of membrane had been discharged. About four weeks after the onset of the haemorrhage she was suddenly seized with acute abdominal pain and faintness, lasting for four to five hours; severe and persistent vomiting followed, and she was very ill for a week, the evening temperature being about 100° F. More haemorrhage occurred at this time, and lasted several days. On January 24th, 1908, she was sent into the Chelsea Hospital for Women by Dr. Aphthor, and two days later I operated. We found a well-encysted collection of blood in the pouch of Douglas the size of a cricket ball; it possessed a complete enclosing membrane, which could be traced to the abdominal end of the left tube, where it was firmly adherent. It was, consequently, a *peritubal* haematocoele, and, along with the affected tube, it was completely removed. The left ovary and the right tube and ovary were healthy, and were not disturbed. The patient made a good recovery.

The probability is that in this case the commencement of the illness with haemorrhage and slight pain after six weeks' amenorrhoea corresponded with some damage to the ovum by intratubal haemorrhage, and possibly some escape of blood through the still patent abdominal ostium. The acute attack of pain, which did not occur until a month later, probably signalized a larger intraperitoneal haemorrhage with expulsion of the ovum (tubal abortion).

The tendency to the recurrence of internal bleeding in extrauterine gestation is one of its most distinctive characteristics, and as this case clearly shows, the recurrence of bleeding, even when inconsiderable in amount, produces well-marked and characteristic symptoms. This tendency to recurrence of haemorrhage provides one of the most powerful arguments against the expectant treatment of these cases, and in favour of the prompt removal of the gravid tube. The liability to progressive or recurrent bleeding is not by any means avoided by confining the patient to bed, as the following instructive case clearly shows:

CASE VI.

Mrs. J., aged 25, bipara, menstruated regularly after her last confinement up to November 22nd, 1907. Six weeks then elapsed without another period occurring, and on January 4th, 1908, she had an attack of abdominal pain, described as being not very severe, and slight vaginal loss of an unusual red colour, which lasted only for a few hours. She was immediately sent to bed by her medical attendant, Dr. Hooper of Sutton. On January 15th, when I saw her first, she was in bed and had every appearance of being in perfectly good health: her pulse and temperature were normal; she had no pain to complain of. There was a little uterine bleeding, and a soft, rather ill-defined swelling, the size of a large orange, was to be felt, behind and to the left side of the uterus. I thought it was a haematocoele arising from a left tubal gestation, but, owing to the extraordinary freedom from urgent symptoms, I hesitated to advise operation, and we decided to try the effect of expectant treatment. The patient was accordingly kept in bed and absolutely at rest for five weeks—that is, until February 17th—and during this time she had little if any pain; her pulse and temperature remained normal, and she constantly expressed herself as feeling perfectly well. But I found the haematocoele had increased very much in size, and now formed a swelling visibly bulging the lower hypogastrium, and extending right across the abdomen up to the level of the anterior superior iliac spines. The next day I operated, and found a large well-encysted haematocoele, and in the dilated outer half of the left tube was a typical tubal mole. She made a good recovery.

This tendency to recurrence of internal bleeding and of the urgent symptoms which indicate it, is not, however, always present, as is shown by the following somewhat unusual case:

CASE VII.

Mrs. P., unipara, aged 27, was sent up to Charing Cross Hospital under my care by Dr. Aphthor, of Harrow, in August, 1906. She had been regular up to December 27th, 1905. Then the periods ceased, and until the following June she was well, and believed herself to be pregnant, and noticed progressive enlargement of the abdomen and breasts. On June 4th, 1906, being then five and a half months pregnant, she was seized with sudden acute abdominal pain, and she fainted; she was kept in

bed, and the case regarded and treated as one of peritonitis, and no further acute attacks supervened. Two days later she passed a piece of membrane 3 in. long, and there was moderate uterine haemorrhage for a few days. Altogether she was in bed about three weeks, and then, on attempting to get up, the acute pain returned, and she had to go back to bed again. She now noticed that her abdomen was getting smaller, and her health remained in a very unsatisfactory condition, with constant abdominal pain, until her admission to the hospital on August 19th, two and a half months after the attack of acute pain. Her pulse and temperature were at this time normal, and her general condition good. An abdominal tumour was found, solid, hard, and tender; it lay behind the ovary, and therefore extended upwards to the right side, to a point half way between the pubes and the umbilicus. It appeared to be quite independent of the uterus, and the history was strongly suggestive of an extrauterine gestation. At the operation on August 24th it turned out to be pregnancy in the undeveloped left horn of a bicornute uterus; there was a fetus of about five months' development, and rupture had occurred with partial extrusion of the fetus, the placenta having been retained entirely within the dilated uterine horn. Omentum and coils of intestine were closely adherent to the gestation sac and the body of the fetus, and there was little free blood found in the peritoneal cavity. The damaged horn was removed, the patient made a good recovery, and has since borne another child.

It appears probable that the development of the ovum was arrested by rupture of the sac at the beginning of June, when the acute attack of pain and fainting occurred; the stage of development of the fetus corresponds roughly with the period of amenorrhoea which had then elapsed. The amount of bleeding caused by the rupture was comparatively trifling, because the placental site was not involved, and consequently the symptoms were not alarming when once the shock attending the rupture had passed away. For two and a half months the fetus and the ruptured sac remained in the abdomen isolated by adhesions, without further haemorrhage, and without infection from the bowel taking place. During the whole of this time the patient was ill, and in more or less constant pain. The rupture of the sac must have been complete, including the amnion, for, as Taylor has shown, the fetus will not be destroyed by rupture of the sac, if the amnion remains intact, and sufficient placental attachment is preserved. There is no doubt that this woman had a lucky escape of her life, for rupture of a cornual pregnancy at the fifth month is usually attended by profuse and often fatal internal bleeding.

Enough has now, I think, been said to show the regularity with which these two symptoms of haemorrhage and pain appear in cases of extrauterine gestation; even when the local conditions found at operation are widely divergent and the corresponding clinical histories show equal differences, these two symptoms are common to them all. And yet, in conclusion, I must warn you not to place a blind reliance upon them; as experience abundantly proves, there is no short cut to diagnosis; each case must be considered on its merits, and symptoms which we have been disposed to regard as reliable guides may at any time play us false if we trust them too readily.

I have quite recently seen a case where the symptoms seemed to justify a diagnosis of tubal pregnancy, and yet entirely different conditions were found at the operation.

CASE VIII.

Mrs. J., aged 22, unipara, was sent into the Chelsea Hospital for Women on January 24th, 1903, by Dr. V. Partridge. Her last regular menstruation had been on June 2nd, 1902. She said that she went a week over her time, and on September 27th severe bleeding set in, with passage of clots, and this continued for three weeks. There had been no very acute attack of pain, but she complained of a good deal of pain in the left side at the beginning of the haemorrhage, and one or two recurrences took place before her admission to the hospital. The bleeding never ceased for more than two days at a time until January 20th, 1903, a examination showed it to be a corpus luteum cyst into which considerable haemorrhage had occurred. The left tube was acutely inflamed and contained pus; the right tube was also much inflamed but not suppurating. On account of her youth I did not remove the right ovary or the uterus; both tubes and the left ovary were, however, removed and the patient made a good recovery.

This was in all probability a case of uterine pregnancy, terminating in an early miscarriage, and followed by infection which spread from the uterus to the tubes. The cyst in the ovary was an accidental complication to which the error in diagnosis was directly due. The weak point in the history was the trivial character of the pain which the patient had suffered and the severity and persistence of the haemorrhage from the uterus. These features ought to have put me upon my guard, but it is obvious that a correct diagnosis would have been practically impossible before opening the abdomen.

THREE RECENT CASES OF TUBAL PREGNANCY.

By C. E. PURSLOW, M.D., M.R.C.P.

HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM.

THE three following cases were operated on by me at the Queen's Hospital recently; they all occurred within the space of three weeks, and, as they present some points of interest, I have ventured to record them.

CASE I.

L. D., aged 34, was admitted on November 12th, and operated upon on November 14th, 1903.

History.

She had been married nine years, and had had three children and one miscarriage, the latter occurring in June, 1907; since then she had not been pregnant. Two months before admission a period came on at the right time, the discharge was darker than usual, and, instead of passing off, it had persisted almost continuously until admission. A fortnight after the onset of the discharge she commenced to have pain in the lower abdomen, worse on the left side: this pain was very severe at times, and then subsided, but never left her.

Condition on Admission.

The uterus was enlarged, and there was a small, ill-defined, very tender swelling in the left fornix.

Operation.

On opening the abdomen, the left tube was seen to be enlarged, and there was some clotted blood around its fibrinated extremity.

Description of Parts Removed.

The specimen removed shows the Fallopian tube and ovary. The tube is dilated in its outer half; its lumen on cross section is about $\frac{1}{4}$ in. in diameter; it is filled with firm blood clots; lying loosely attached to its fibrinated extremity is a small firm blood clot, having precisely the retort shape of a distended Fallopian tube; this is apparently a mole which had been recently expelled.

CASE II.

H. R., aged 30, was admitted on November 26th, and operated upon on November 28th.

History.

She had been married four and a half years, had had one child three years ago, but no abortions. Six weeks previous to admission she had commenced a period at the time expected; this lasted two days and then ceased; three days later it recurred, and had continued, off and on, until admission. Ten days after the commencement of the flow she was taken with very severe pain, which began in the right shoulder, and then spread to the lower abdomen and perineum; three weeks later she had another attack of pain and a rigor. There had also been some difficulty in micturition and well-marked rectal tenesmus; the pain had persisted up to the time of admission.

Condition on Admission.

The lower part of the abdomen was tense and extremely tender; there was a distinct series of swelling above the pubes. On vaginal examination there was a distinct swelling in Douglas's pouch with very marked tenderness.

Operation.

On opening the abdomen there was a small amount of blood in the peritoneal cavity, and the left tube was greatly enlarged and lay behind the uterus; it was removed, and on subsequent examination it was found to form an oval swelling having a diameter of 2 in.; its walls were found to be thickened and its interior filled with firm blood clot.

CASE III.

E. C., aged 32, was admitted on December 3rd and operated upon on December 5th.

History.

She had been married nine years and had had one child seven years ago, and an abortion at the third month six months ago; after that, menstruation had been regular until October 1st, when her last period occurred; from that time until fourteen days before admission there was amenorrhoea and subsequently irregular loss. Eighteen days before admission there was a sharp attack of pain in the abdomen and back passage, and

there had been slight diarrhoea and rectal tenesmus, and the severe pain had recurred on four occasions, the most severe attack being two days previous to admission.

Condition on Admission.

The patient was very pallid and the pulse small and frequent, and on examination there was a large, tender, soft swelling behind the uterus, and the latter was enlarged and pushed forward by the swelling.

Operation.

On opening the abdomen a large mass was seen covered by omentum; on detaching the latter the tumour was found to consist of clotted blood, and this together with the tube and ovary was removed.

Description of Parts Removed.

The tube was found to have an extensive rupture on the upper surface of its ampullary portion. On cutting open the clots after they had been hardened in formalin one was found to contain a distinct amniotic cavity with a small embryo.

It will be noted that in only two of the cases did any interval of amenorrhoea precede the onset of symptoms, and, in my experience preceding amenorrhoea does not occur in more than 50 per cent. of cases of extrauterine gestation. The symptoms present in each of these cases were:

- (1) Irregular and unusual loss of blood per vaginam;
- (2) Intermittent attacks of severe pain in the lower abdomen;
- (3) The presence of a tender swelling in the pelvis;

and I believe that these are the most constant symptoms of extrauterine gestation after some disturbance of the ovum has taken place.

1. *Hæmorrhage*.—The loss is frequently found to be unusual and to differ from normal menstruation both in its mode of onset and continuance, and in its character; thus it is often described as being darker than usual, or as having a brown colour.

2. *Pain*.—In two of the cases rectal tenesmus was a well-marked symptom, and, if inquiry is made, it will be found that this symptom is frequently present, especially with the first onset of the pain. The pain in the shoulder complained of by one patient is an unusual symptom, but it has been noted by other observers in cases of intra-peritoneal hæmorrhage. It is worthy of note that the case with the most serious symptoms proved to be a tubal rupture, and in the two with less marked symptoms there was no rupture but hæmorrhage from the fibrinated opening. I believe that it will generally be found that the more severe symptoms are associated with tubal rupture and the milder with tubal abortion, but this relation is not constant and is not a safe guide to a differential diagnosis between the two conditions.

TREATMENT.

The first point to decide is whether surgical or expectant treatment should be adopted. There can be no doubt that a proportion of cases get quite well without operation, but the difficulty is to decide in any given case whether expectant treatment can safely be trusted. I should myself limit it to cases in which there are definite signs of hæmatocele but all evidence of active hæmorrhage has ceased—that is, pains have disappeared, and the pulse, temperature, and colour of the patient are normal. If adopted it is essential that the patient should be kept in bed and should be within reach of surgical assistance should further intraperitoneal hæmorrhage take place.

As regards "route," I would limit the vaginal to cases of well-marked hæmatocele in Douglass's pouch, with symptoms pointing to suppuration of the blood mass.

In each of these cases the Trendelenburg position was used; the slight risk of blood escaping into the upper regions of the abdomen is more than counterbalanced by the much greater readiness of access to the field of operation, and by the avoidance of handling of intestine which is possible in this position. I did not wash out or drain in any of these cases, and have long abandoned both washing out and drainage for cases of this kind. The abdominal wall was sutured in layers, the wounds healed by first intention, and each of the patients left the hospital on the nineteenth day after operation.

I am indebted to my house-surgeon, Mr. R. C. Allen, for many of the notes, and for much valuable assistance in the treatment of the cases.

THE SURGICAL TREATMENT OF THE UMBILICAL CORD.

By J. W. BALLANTYNE, M.D., F.R.C.P.E.,

PHYSICIAN TO THE EDINBURGH ROYAL MATERNITY HOSPITAL.

No obstetrician who gives a thought to the matter can ever feel that he has treated the umbilical cord in a surgical, not to say aseptic, manner when he has applied a ligature to it about 2 in. from the navel, divided it, and wrapped the stump round with a piece of sterilized gauze. Nevertheless, that is the method which is still almost universally employed, with the addition, in the practice of maternity hospitals and of certain obstetricians, of antiseptic applications on one or more occasions to the cord-stump. It may be said, in defence of the old-established plan, that it works very well, and that umbilical infection in the new-born infant is only an occasional occurrence; and it is quite true that in most cases neither septic nor sapraemic invasion of the tissues of the child takes place, or, rather, it ought perhaps to be said that if it does occur, it is not ascribed to the state of the funis.

Yet there are certain facts which ought to provoke reflection. C. Keller, for instance, in an article on the relation of umbilical infection to infantile mortality in Berlin,¹ has shown that 2 per cent. of the total mortality of children is due to umbilical infection during the first month of life; he has also pointed out that the results of the infection are chiefly sepsis, tetanus neonatorum, peritonitis, inflammation of the navel, omphalorrhagia, and intestinal disturbances. Keller, therefore, had adopted stricter antiseptic methods of dealing with the cord, such as drying and disinfecting it with pledgets wrung out of a solution of alcohol (96 per cent.). There is also evidence that umbilical infection is more likely to occur in premature infants; and I pointed out in a contribution to a short-lived journal² that there was reason to believe that delayed closure of the umbilical arteries and vein might account for this greater liability. In proof I instanced, among other things, the cases reported by the Audouins,³ in which systemic infection had apparently taken place through the umbilicus, and had been pre-disposed to by the persistent permeability of the umbilical vessels, and I stated that these cases should make us more careful in our inspection and treatment of the umbilical depression and the funic stump. Further, in an article on the Problem of the Premature Infant⁴ which I published in 1902 I attempted to distinguish between the risks of umbilical infection run by the mature as compared with the premature infant thus: In the former the umbilical route was effectually closed in part by the ligature of the cord, but more especially by the obliterative changes which took place in the umbilical vessels; but in the case of the premature infant the closure of the umbilical arteries and vein was apt to be incomplete, and septic and other pathogenic organisms found their way into the body on account of the persistent permeability of these vessels; the results of the infection were sometimes evident in the immediate neighbourhood of the umbilicus, in the form of peri-umbilical inflammation of an erysipelatos type, but at other times the umbilical vessels showed no morbid changes save permeability, and the pathological consequences of the microbic invasion might be found in the liver, the heart, or in some distant organ such as the brain. As I got a larger experience of hospital midwifery practice I was able to assure myself that the risks of umbilical infection in the premature infant (as stated above) were not exaggerated, and that even full-time children were not uncommonly the subjects of similar although less serious dangers. In fact, it seemed to me that many of the instances of so-called icterus, or jaundice of the newborn, might be ascribed to transitory attacks of hepatitis set up by microbes which had found their way to the liver by the umbilical vein from an infected umbilical stump or scar.

For all these reasons I was led to scrutinize closely the various methods of dealing with the cord which were being tried in a sort of sporadic fashion by different obstetricians in various places. There was Bacon's plan, for instance,⁵ by which the Whartonian jelly was cut at the base of the cord and the vessels tied with fine silk or catgut, after which the umbilicus had to be kept

perfectly sterile; there was Duke's method by means of a simple form of clamp, which reduced the portion of dead funic tissue adhering to the abdominal wall to a minimum;⁴ and there was the procedure recommended by Schell,⁷ in which the cord was first clamped and washed in an antiseptic lotion, and thereafter dealt with in detail, the covering being divided at the amnio-dermal junction, the jelly stripped away, and the vessels ligatured with catgut and cut off close. It was not, however, till the autumn of last year—when I was physician in charge of the Edinburgh Royal Maternity Hospital—that I had an opportunity of carrying out a series of experiments upon various modes of dealing with the cord which should more nearly attain to the standards of surgical asepsis than simple ligation of the whole thickness of the funis with thread or silk did. I am greatly indebted to Mr. J. Gibson Craig, M.B., Ch.B., F.R.C.S.E., one of the resident surgeons during the quarter, for carefully carrying out the different procedures now to be described; in fact, Mr. Craig's was by far the more onerous part of the experiment, for I simply proposed the various methods which were tried and supervised the results. In all, 16 experiments were made during September and October, 1908, and six different plans of dealing with the cord were used. I shall now describe the methods and the results.

CASE I (Method A).

A female infant, the second child of a married woman, 25 years of age, weighed 7 lb. 6 oz. at birth. The cord was cut through with scissors 1½ in. from the umbilical ring; the fetal end was grasped between the forefinger and thumb of the left hand while Wells's artery forceps were applied singly to the umbilical vein and the umbilical arteries; these vessels were then ligatured separately with No. 1 catgut; the sheath of the cord was stitched over the resulting stump and united with fine silk sutures. On the third day the child weighed 7 lb., on the fifth 6 lb. 14 oz., on the seventh 7 lb. 2 oz., and on the eleventh 7 lb. 6 oz. It never showed any jaundice. When the child left the hospital there was a dry, black scab at the umbilicus, closely resembling that seen when the cord is treated in the ordinary fashion—that is, by ligation.

CASE II (Method A).

A female infant, weighing only 5 lb. 14 oz.; it was the first child of an unmarried girl, aged 20 years. The cord was treated exactly as in Case I, and the result did not differ in any obvious manner from that obtained in ordinary ligation of the funis. On the third day the child weighed 5 lb. 9 oz., on the fifth 5 lb. 6 oz., on the seventh 5 lb. 12 oz., on the ninth 6 lb., and on the eleventh 5 lb. 15 oz. There was no jaundice.

CASE III (Method B).

A female infant, weighing 6 lb. 15 oz.; it was the first child of an unmarried girl, aged 21. The clamp was applied to the cord 1 in. from the umbilicus; it was then tightened as much as possible, crushing the end of the cord stump, and it was then removed, no bleeding following. By the pressure of the clamp the jelly had been expressed from the part of the cord in its grasp, and the covering of the cord formed naturally a hood over the stump. The sheath was then sewed over the stump with a continuous silk suture. Rather much pressure was applied in this case, with the result that a slight tear was caused in the epithelial covering of the funis running for about ½ in. in its long axis towards the umbilicus; this was covered with a continuous Lembert suture of silk. No ligation was applied to the vessels or cord, the pressure of the forceps having been sufficient to stop all bleeding. On the fifth day the infant weighed 6 lb. 9 oz., on the seventh 6 lb. 11 oz., on the ninth 6 lb. 10 oz., and on the twelfth 6 lb. 9 oz. There was no jaundice. When the child was discharged the cicatrization at the umbilicus was nearly complete and the result was better than in Cases I or II.

CASE IV (Method C).

A male infant, weighing 8 lb. 9 oz., the first child of an unmarried girl of 21. The sheath of the cord was cut through with a scalpel in a circular fashion about 1½ in. from the umbilicus, but the umbilical vein lay so superficially that it was nicked in the process. An attempt was made to catch hold of the wounded vein with the artery forceps, but this was unsuccessful, and so the cord was cut through with the knife; even then the vessels were so brittle that forceps applied to them tore off. Finally a silk ligature was applied round the whole cord 1 in. from the umbilical ring, and the cord was cut short immediately distal to it. The edges of the sheath were brought together with silk sutures. In this case, therefore, the attempt to treat the cord by stripping back the sheath failed, and the method adopted was really the ordinary one of ligation, with the addition of the sheath. The cord sloughed off on the eighth day, the process being quite dry. There was no jaundice. The infant's weight on the third day was 8 lb. 5 oz., on the fifth the same, on the seventh 8 lb. 6 oz., on the ninth 8 lb. 7 oz., on the eleventh 8 lb. 13 oz., and on the thirteenth 8 lb. 14 oz.

CASE V (Method C).

A female infant, the third child of a married woman aged 27. It weighed at birth 10 lb. 1 oz. The sheath of the cord was cut

through 1 in. from the umbilicus, and the attempt was made to strip it back on the fetal side of the circular cut, so that the vessels could be secured, and then it was intended to pull the reflected sheath over the ligatured vessels and stitch it there. Unfortunately it was found that Wharton's jelly did not lend itself so easily to removal as, perhaps, a more solid substance would, and although the purpose was attained after a fashion, it was far from being an easy or a neat procedure. The results did not differ from that obtained by the ordinary method of ligation, and the stump separated on the twelfth day. There was never any jaundice. The weight of the infant on the third day was 9 lb. 11 oz., on the fifth day 9 lb. 12 oz., on the seventh 10 lb. 1 oz., on the ninth 10 lb. 2 oz., on the eleventh 10 lb. 7 oz., and on the twelfth day 10 lb. 8 oz.

CASE VI (Method D).

A female infant, weighing 8 lb. 3 oz., the first child of an unmarried girl, 20 years old. The cord was grasped between the left thumb and forefinger close to the umbilicus; a circular incision with a knife was made through the whole cord 1½ in. from the navel, and the vessels were picked up separately with artery forceps and ligatured with catgut. The same difficulty was met with as before, namely, tearing of the vessels; and yet, if the attempt was made to tie the vessels with Wharton's jelly adhering to them, the ligatures always slipped. The sheath was stitched over the stump. There was no jaundice, the cord separated on the tenth day. On the third day the body weight was 7 lb. 8 oz., it was 7 lb. 9 oz. on the fifth day, 8 lb. on the seventh, 8 lb. 3 oz. on the ninth, and the same on the eleventh day.

CASE VII (Method D).

A male infant, weighing 5 lb. 12 oz., the first child of an unmarried girl, 21 years old. The cord was treated as in Case VI, and separation of the stump took place on the twelfth day. On the third day the child weighed 5 lb. 3 oz., on the fifth 5 lb. 3 oz., on the seventh and ninth 5 lb., and on the eleventh 5 lb. 2 oz.

So far our experiments with surgical methods of treating the cord showed very little advantage over the ordinary plan of ligation *en masse*. It could not be said that the weight of the infants had been beneficially affected; and, although there had been no jaundice in any case, it was doubtful whether this immunity could be ascribed to the method adopted.

CASE VIII (Method D).

A male infant, weighing 5 lb. 14 oz. at birth, the second child of a married woman, aged 31 years. The method of dealing with the cord was the same as in Case VI, save that the circular incision was made ½ in. from the umbilicus. There was no jaundice, and the cord separated on the eighth day. The body weight was 6 lb. on the seventh day, and 6 lb. 2 oz. on the eleventh.

CASE IX (Method E).

A male infant, the seventh child of a married woman, aged 28, weighed 6 lb. at birth. A circular incision was made with a knife through the sheath of the cord as near to the umbilical ring as possible without cutting the skin. A perineal needle was then used to transfix the cord in the way the ovarian pedicle is treated. A piece of catgut (No. 3) was pulled through on the needle, so that when the catgut was divided to release the needle two pieces of catgut were left transfixing the cord; the two pieces were now tied, each one constricting one-half of the cord. The funis was now divided just outside the ligatures, and the sheath was brought over the raw end and stitched there. On the twelfth day a little black scab of the size of a three-penny piece was found attached to the umbilicus. The child's weight on the third day was 5 lb. 6 oz., on the fifth day 5 lb. 7 oz., on the seventh 5 lb. 10 oz., on the eleventh 5 lb. 11 oz. and on the twelfth 5 lb. 12 oz. There was no jaundice.

CASES X, XI, AND XII (Method E).

Cases X and XI were female infants, weighing 8 lb. 6 oz. and 7 lb. 5 oz. respectively, the children of married women, aged 24 and 22 years; and Case XII was a male infant weighing 9 lb. 6 oz., the child of an unmarried girl of 18 years. In all of them the cord was treated as in Case IX, and in all a small black scab was left at the end. Dr. Craig was of opinion that the time this procedure required was too great for ordinary use, and that the method itself had no advantages to warrant its adoption. Further, it had some disadvantages: in the first place, there was the prolonged exposure of the child at least ten minutes, when everything went smoothly; second, there was the risk of ligatures slipping and consequent loss of blood; and third, the procedure could only be carried out with the assistance of two persons, one to look after the mother and keep a hand upon the fundus uteri, and the other to control the movements of the child.

CASES XIII, XIV, XV, AND XVI (Method F).

With these four infants—two boys and two girls, the children of three unmarried girls and one married woman—a new plan of procedure was tried: in all of them the cord was cut off flush with the skin of the umbilicus, and the skin surfaces were joined. With a scalpel a circular incision was made at the junction of the skin of the infant with the sheath of the cord; gradually the incision was deepened until the vessels were approached; then by careful dissection the vessels were cleared from the jelly and tied separately; next the cord was severed; and finally, the edges of the skin were rawed and united together, in one case with silkworm gut, and in the other three

with cauter. The time required for the operation was ten minutes. No jaundice occurred in any of these infants, and their weights were well maintained. With regard to the umbilicus, there was in these four cases a very remarkable result, as compared with all the others. On the fourth day in each case the umbilical stumps were quite healed, and the cicatrix was already retracted. The stumps had healed like ordinary surgical wounds kept aseptic. The good results were evidently due to the complete removal of all the dead structures and to the freshening of the cutaneous surfaces; no putrefactive changes took place and the surfaces united by first intention. At first it seemed to us that there might be apprehension of danger from ligatures so near the umbilical ring slipping; but, as a matter of fact, it was found that the supporting structures were firmer near the umbilicus than at a distance from it, and there was actually less risk of slipping and consequent hæmorrhage.

These experiments brought home very clearly to my mind the conviction that, if the umbilical cord was to be treated on strict surgical principles, Method F was the only plan which fulfilled all the requirements. All the other procedures left pieces of funic tissue to separate by putrefaction, and the process of cicatrization was apparently lengthened rather than shortened. It was certainly remarkable that none of the infants showed jaundice; but I cannot confidently affirm that their immunity was due to the unusual treatment given to the cords. It was also very satisfactory that none of the children had any morbid developments, and as a rule regained their original weight well; but, again, it can hardly be claimed that this result was the consequence of the various modes of dealing with the umbilicus, although they may have contributed to it.

The sixth plan (Method F) certainly gave very satisfactory results, for to obtain a cicatrized and retracting umbilical scar at the fourth day was something worth working for. The great objection to it which will at once come into the mind of the general practitioner, as well as into that of the maternity hospital surgeon, is the length of time it requires and the fact that it takes the medical attendant away from the mother at a critical part of the third stage of labour. The second difficulty might be got over by clamping the cord temporarily and treating it surgically after the third stage is over; and the first objection will, of course, become less formidable as the obstetrician acquires skill in the performance of the necessary manipulation. I am inclined to think that this method will find its greatest usefulness in cases in which at previous confinements there was evidence of umbilical infection of the new-born infant, more especially when such infection occurred in prematurely born infants, in whom we must suppose the umbilical vessels are more liable to remain permeable for a time. I do not think we can hope that it will yet be adopted as the routine treatment of the umbilical cord, but I trust that it will be found useful in cases where infection through the umbilicus is dreaded, and by obstetricians who are dissatisfied with the ordinary method of ligaturing the funis.

A CASE OF CHRONIC INVERSION OF THE UTERUS.

WITH REMARKS ON THE MECHANISM OF REINVERSION.*

By R. J. JOHNSTONE, M.B., F.R.C.S.,

ASSISTANT Gynaecologist, Royal Victoria Hospital, Belfast; SURGEON, BELFAST MATERNITY HOSPITAL.

THE following is a brief history of the case:

Mrs. M'C., a primipara, aged 24 years, was delivered on November 29th, 1903. Labour was slow, and forceps were used to complete delivery. The expulsion of the placenta gave some trouble, and was followed by copious loess. This was checked by hot douches, but slight hæmorrhage persisted during the whole of the puerperium, and a profuse bleeding occurred on December 25th. Other symptoms were obstinate constipation, and a "feeling of something coming down," which was only present during micturition while she remained in bed, but became constant on her rising at the fourteenth day.

I saw her on December 26th. She was very anæmic, and on

examination presented the typical signs of a chronic inversion of the uterus. The inverted organ was of about the size and shape of a large hen's egg, and was soft and elastic in consistence. I looked for the orifices of the Fallopian tubes, but failed to discover them. Attempts at taxis, both without and with an anæsthetic, made no impression on the displacement. We then decided to try repositors. I was unable to procure Aveling's, which are highly recommended, and had to take an instrument designed by a Mr. Lawson Tait. I inserted his largest repositr on December 28th, and as no effect had been produced used a No. 1 tightened up the elastic bands. Two days later the cervix was re-formed, and two days later still the apex of the inversion was flush with the external os. On the next day it had receded within the widely dilated cervix. Wide as the cervix was, Tait's smallest repositr could only have been inserted into it with considerable difficulty. I contented myself therefore with putting a small plug of gauze in the vagina. On removing this two days later, eight days after treatment had been commenced, the uterus could be felt bimanually in its normal position and completely reinverted.

One or two points in this case are worthy of a remark in passing.

1. Unskilful conduct of the third stage has been often assigned as the cause of this accident. The method employed in this case was a combination of expression and gentle traction on the cord, and has served the practitioner who was in charge of the case for twenty years, during which he has never had any trouble. If undue pressure on the fundus or traction on the cord are the causes of this displacement, why is it the rarest complication of midwifery? Dr. Athill has recently revived the view originally taken by Crosse that inversion is due to attachment of the placenta to the centre of the fundus, and on examining the inverted organ in this case I detected a rounded area about as large as a halfpenny on its apex. This area was slightly deeper in colour and less smooth than the surrounding mucous membrane. It may have represented the placental site, but, on the other hand, it may have been caused by inflammatory changes in the part most dependent and most exposed.

2. It is worth noting that the accident was quite unaccompanied by shock, which seems to be regarded as a constant symptom by all but the most recent authorities.

3. The last point to which I wish to direct attention is in connexion with the treatment of this case. The classical method of using repositors is, of course, to begin with the largest size and to end with the smallest, which is introduced into the cavity of the uterus, and remains there until reduction is effected, whereupon it is recovered, often with considerable difficulty if one may judge by reports. It will be noticed that in this case, as it was not easy to introduce the smallest repositr into the cervix, it was dispensed with altogether. This was done advisedly and on the following line of reasoning: Inversion occurs while the cervix is stretched and its muscular fibres paralysed. If the fundus be not reduced before this paralysis has been recovered from, the restoration of tone to the cervical muscular fibres effectually closes the cervical canal against the return of the uterine body, and this resistance can only be overcome by continuous elastic pressure, as with the repositr, or by forcible dilatation or section. But once the apex of the inverted uterus has come within the cervix the tone of the cervical muscle fibres, which has been overcome but by no means abolished by the pressure of the repositr, bars the way against subsequent extrusion of the fundus, and the effect of the muscular contraction of the containing shell of uterus on the contained partially inverted fundus must be to drive it upwards and to reinvert it. Cases of inversion due to tumour stand in a different category.

CONCLUSION.

The practical point which I wish to make is that in reducing inversion by means of repositors there is, on my theory, no need to use an intrauterine instrument, troublesome to introduce and to withdraw. I suggest that when the fundus has been reduced within the external os the use of repositors may be discontinued, and the uterus will reinvert itself, like an india-rubber cup, turned not quite half inside out. I am well aware that one case is quite insufficient to base a theory upon, but I think my suggestion is at least plausible, and I would ask those who may have an opportunity of testing its value to do so. The experiment can do no harm, and if it does not succeed one can still fall back on an intrauterine repositr and recover it afterwards by means of "elastic bands fastened to the foot of the bed."

INGUINAL HERNIA OF UTERUS:

HERNIOTOMY WITH RADICAL CURE: UNUSUAL COMPLICATIONS: RECOVERY.

By RUSHTON PARKER, M.B., B.S., F.R.C.S.

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LIVERPOOL.

A LADY, aged 47, was brought to me in October, 1907, by Dr. Prichard, of Conway, for double inguinal herniotomy. The right hernia had existed many years, but had only been troublesome four or five, and had become constantly painful. During the past fortnight symptoms of obstruction had occurred, lasting three days. The left hernia had formed gradually, and had never given trouble. Both felt like, and were supposed to be, omental ruptures.

On October 19th, 1907, double herniotomy was performed in a home in Liverpool, with the aid of Dr. Prichard and an anaesthetist. The right hernia was found to contain an ovary, Fallopian tube, broad ligament, and a small, elongated uterus, which at the moment was taken for the right half of a "bicornis," all enclosed in a peritoneal sac. There was no means of reducing the contents, which were accordingly removed. In doing this careful search was made for a portion or trace of vagina, but none was found, either then or after dissection, of the specimen. But the finger was passed into the vagina, at this stage of the operation, without

obstacle, and without any discovery of note. The stump was stripped in detail with dissecting forceps and the shreds tied and returned into the abdomen. The hernial sac was stripped, closed with a Staffordshire knot, and cut off beyond. On the left side the contents were omentum, the narrow neck of which was tied and its stump returned. The hernial sac was closed as on the right side, the pillars of each ring closed, and the wounds sewn up. Both wounds healed by first intention in three days and the herniae continue

soundly cured. But the patient became uneasy as soon as she recovered from the anaesthetic—that is, the same afternoon—complaining of continual abdominal pain and inability to pass wind, with slight but increasing distension. She could not sleep, and got no relief from several doses of opium with abstinence from all food of any kind.

By the fifth day, October 23rd, she was so decidedly worse that median abdominal section was performed, and Dr. Prichard came over for the purpose. Attached to and blocking the sigmoid flexure there was found a hard lump resembling and taken for a small carcinoma, all the gut being distended above this point.

As a special precaution, and to avoid contamination of the parts before closure, a loop of bowel, with the lump superficial, was closely sewn to the peritoneum, and its contiguous sides attached to each other, in the middle of the opening; the abdominal wall above and below being closely sewn with detailed suture of the aponeurosis; and, finally, the gut opened above the growth, and a wide glass tube tied in, so that faeces were conducted away outside the dressings, without leaking into the wound. Before attaching the gut or in any way closing the abdomen, careful search was made in the pelvis for the left ovary and appendages, and for the left half of the supposed "uterus bicornis"; but nothing whatever could be found of such parts. On attempting a vaginal examination during this operation the finger could not be passed more

than an inch or little more, that tube being now tightly closed at that distance from the vulva. These discoveries were mysterious at the time, and have since not yielded any explanation.

No further symptoms of bowel obstruction occurred; the patient became, however, very excited, and at times almost unmanageable, owing to restlessness and frantic complaints of pain. So hypodermic injections of morphine sulphate were resorted to, usually three times daily, but often less, in doses that had to be increased until the quantity would have alarmed me were it not that I could not manage with less, though frequently diminishing it secretly. The necessary relief was always obtained, although often postponed by cutting the doses short. Nobody but myself administered the drug, or knew the dose given, and it would serve no useful purpose to mention the quantities. No other drug was ever combined with it, and so its exact and real value were always perfectly clear. This process was kept up for four and a half months, not a week passing without many attempts by postponement and diminution to make her do with less. In a fluctuating way these efforts succeeded, but her suspicions were never aroused. The drug was only at first progressively increased. The maximum doses were quickly arrived at, and, once reached, had never to be exceeded.

In a very few days after this second operation the tube separated, and the faeces leaked from the fistula thus made, but were kept from the sewn parts of the wound by interposing folds of cyanide gauze plentifully smeared with eucalyptus ointment. These parts of the wound healed quickly and well, but still the faeces irritated portions of the skin around, and also caused a partial reopening of the right inguinal wound for a time. However, with firmer ointments, medicated with boric acid or eucalyptus oil as found convenient, these inconveni-

ences were gradually overcome, and the faecal odours counteracted, between the changes of dressing, by pads of odoriferous carbolized tow and sprinklings of lavender water.

Exactly two months after the colostomy a third operation was undertaken. As the patient had begun to hold her ground, though much reduced in flesh, and was becoming frantic at the prospect of a permanent faecal fistula, the parts were examined in consultation with Mr. F. T. Paul, with the view of removing the growth on the colon. Its situation had receded, and enemas given by the rectum immediately welled out of the fistula. After clearing the rectum, which had gradually accumulated faeces, enemas were given both ways, and the agreeable and unexpected discovery made that the finger revealed smooth bowel in both directions from the fistula, and no trace of tumour. There was a good spur of bowel behind its attachment round the fistula, so the future proceeding was evidently much simplified; and on December 23rd, 1907, the spur was compressed in a clamp which cut its way gradually through after tightening a screw on the handles, and came away in little over a week, and faeces were found to be reaching the rectum, though most passed by the fistula.

On January 9th, 1908, a fourth operation was done, bringing the edges of the skin by deep mattress sutures, and superficial stitches over the fistula. In three days

Contents of right inguinal hernia, consisting of small uterus (with fibroid in cervix), right Fallopian tube, broad ligament, and ovary flattened out and thinned by pressure while lying under other specimens. (Photograph in water, after 15 months in formal solution, by Fred. Halliday, Museum Attendant.)

faeces leaked out, but the stitches were left in for three weeks and the parts cleansed by daily irrigation. Five weeks later she passed a voluntary stool, in the sitting posture, and daily afterwards, when the leakage became obviously less in three more days. After six weeks she sat up daily, the morphine was much reduced, unknown to her, and less than a week later she volunteered to go without it, and it was then abruptly discontinued. A week later (March 13th) she went home, took her nurse with her, and final healing occurred by the end of that month. Gradual improvement took place, resumption of ordinary diet, carriage exercise, and open-air life in house or garden.

Some violent attacks of abdominal distension and constipation occurred, through reckless feeding; but were corrected by enforced fasting and rest in bed. It had to be impressed upon her that owing to the attachment and probable stricture or other deformity of the bowel, she would have to practise great frugality to avoid imminent danger.

By August, 1908, she was perfectly well, and at Christmas she went from home on a visit of several weeks, being in full health and vigour, with firm scars at all the sites of operation; and no impulse in the groins or any trace of hernia, but still a closed vagina.

CAESAREAN SECTION WITH UNUSUAL INDICATIONS.

By R. C. BUIST, M.A., M.D. DUNDEE,

LECTURER IN CLINICAL OBSTETRICS IN ST. ANDREWS UNIVERSITY.

ORDINARILY a Caesarean section is looked forward to as one of the possibilities of a particular case, and preparations for it are made in due course, but in the case which I am to narrate, until I was actually in immediate presence of the need, I had no thought that delivery in this form might be called for. As there were none of the classical indications and the ordinary conditions of election for its performance were all violated, the notes of the case may have interest for members of the profession not in special practice.

Mrs. M., aged 46, was seen by me on September 20th, 1908, with a view to her prospective confinement. She had had four previous pregnancies, the last three ending at term with rather large children ranging up to 9 lb. weight, and each requiring delivery by forceps. The last confinement was ten years ago. Her last period was in the end of March and she had quickened in mid-August. During this pregnancy she had felt unusual fatigue, and on examination she showed great abdominal distension. There was evident hydramnios and the uterus was almost as large as a uterus at term. The fetal length, however, corresponded to the assigned date of menstruation. Arrangements were therefore made for a confinement early in January. The patient's comfort was added to by a special bandage, but she had from this time mostly to keep her bed.

The nurse engaged for January got tired of waiting and took another case, and a second proposed for February had also to go, and it was not till I had decided on puncturing the membranes that the labour came on spontaneously. I had seen her frequently but never found any sign of engagement of the presenting head.

On February 19th, almost eleven months after the last menstruation, I was called at midday, and found that she had been in labour since the morning. The os was fully dilated, but the head not engaged. I ruptured the membranes to relieve the hydramnios, and then recognized that the fetus was an anencephal, and of large size. As this condition put delivery by forceps practically out of the question, I gave the patient chloroform and brought down the left foot, only to find that the breech would not enter the pelvis. I then brought down the other foot, and found that no amount of suprapubic pressure and traction on the legs which I could exert would bring the pelvis into the brim. At this deadlock, embryotomy was the next consideration, but it was evident that with legs corresponding to the size of the feet we saw protruding from the vulva it would be so difficult to reach the child's pelvis above the brim that with the subsequent necessary crushing of the shoulder girdle and skull base, embryotomy was to be a perilous process for the mother. I therefore asked and received the husband's consent for Caesarean section, and went to the telephone in search of an assistant and some catch forceps. I was fortunate in finding Mr. Price, who said he would bring both instruments and dressings. Pending his arrival at 5 p.m. I prepared the abdomen and kept the patient under light anaesthesia.

The operation, made with a vertical incision, presented no unusual feature except that the extraction of the child which I had so forcibly tried to bring through the pelvis was more than ordinarily difficult. After the child was extracted, the uterus was extruded, the placenta extracted, and the uterus sutured with catgut. The abdominal wound was sutured with silkworm gut, and dressed with sterile gauze.

Mr. Price and I were able to leave at 6 p.m., and the 60 c.cm. (2 oz.) of chloroform with which I started the afternoon were not exhausted. The puerperium was as smooth as after an ordinary confinement. There was no sickness. The temperature never rose over 99° F., and the wound healed normally. The patient was out of bed on the fourteenth day, and on the twenty-ninth day was able to go down town to see a play in which her children were engaged.

The child breathed for a few minutes. It measured 21½ in. to the skin border over the eyes, and 6 in. round the calf. It weighed 10 lb. The mother is a small woman but well developed, and has little if any pelvic contraction.

While I have no doubt as to the rightness of the management in this case, my expectation of performing Caesarean section in a practically normal pelvis is not high. The difficulties encountered seem to me such as are more likely to occur in general practice than in hospital.

TETANUS OCCURRING AFTER SURGICAL OPERATIONS:

IS THE INFECTION INTRODUCED BY CATGUT LIGATURES?

By W. G. RICHARDSON, M.B. DUNDEE, F.R.C.S.,

SENIOR ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

ON September 30th, 1907, I operated upon an elderly lady, and removed a large number of gall stones from the gall bladder and cystic duct. After the operation the patient made most satisfactory progress in every way until October 6th, when some rigidity of the muscles of the neck appeared, followed rapidly by trismus and other well-marked symptoms of tetanus, from which disease the patient died within forty-eight hours of its onset.

I had heard of tetanus following upon surgical operations before this calamity overtook my patient, and I at once suspected that the bacilli of tetanus had been introduced in the catgut ligatures used at the operation, because in all the cases of which I had heard the same suspicion had been cast. Catgut was the material which I had used for ligatures and for deep sutures; the only other material which I had employed being silkworm gut for sewing up the wound in the skin. All the catgut in my possession was examined for me bacteriologically, and the report states that "the experiments made with this material to detect the presence of *Bacillus tetani* have proved absolutely negative. The catgut is absolutely sterile."

After receiving that report I was entirely baffled in the attempt to find a source from which the infection could have arisen, and I am still in the dark.

In January, 1909, I operated upon a middle-aged man for strangulation of the omentum in the sac of a right inguinal hernia. I used catgut for ligaturing the neck of the sac, for the blood vessels and for the deep sutures, and silkworm gut for suturing the skin. The patient did well and left the infirmary, with the wound healed, in fourteen days. A week later he was admitted with tetanus, from which he died two days later.

I have spoken to many surgeons upon the subject, and they all believe firmly that the infection is conveyed by catgut ligatures—not one of those with whom I have been in communication appears to have a doubt about it. One surgeon, who had two cases within eight weeks of each other, wrote as follows:

I had catgut and the pedicle from the fatal case examined both here and in London, with no particular result. No organisms were found in the catgut, and the cultures from the pedicle, though "resembling" tetanus bacilli, were negative in experiments upon animals. I am not sanguine of any more definite result being obtained, except in cases where tetanus bacilli are proved to exist in the catgut. I am morally certain that in my cases the catgut was responsible.

That accurately sums up the belief of those whose opinions I have obtained. It may be that such a belief is correct; indeed, in view of the fact that catgut was used in all the cases of which I have any knowledge, it would appear undeniable, and yet it must be confessed that no positive evidence has been adduced which entitles us to condemn catgut.

I have collected notes of 21 cases in which tetanus has followed a surgical operation; 20 of the cases have occurred during the past three and a half years and 1 occurred as long ago as 1884:

Of the 21 operations—

- 4 were for ovarian cysts
- 4 were for removal of the uterus
- 4 were for radical cure of hernia
- 3 were for gall stones
- 1 was for acute pancreatitis
- 1 was for acute appendicitis
- 1 was for ventral fixation of the uterus
- 1 was for carcinoma of the rectum
- 1 was for varicella
- 1 was for scirrhus of the breast

18 of the patients died.

In all the cases catgut was used for ligatures. In 14 of the cases the catgut was submitted to bacteriological examination with a view to the detection of the *Bacillus tetani*. In 4 a bacillus "resembling" the tetanus bacillus was cultivated from the catgut, but no animal has been infected with tetanus by means of the cultures in those cases in which the experiment was tried. In 1 case the catgut was found to be sterile, but cultures of a bacillus were obtained from the pedicle of an ovarian cyst, for which the patient had been operated upon, and which was removed after death, but it was not found possible to cause tetanus in animals by inoculation with the cultures.

Thus it appears that in spite of careful search there is no positive evidence of the existence of tetanus bacilli in the catgut.

Before going further into these cases, I would like to refer to the late Professor D. J. Hamilton's paper on the Alimentary Canal as a Source of Contagion. In it he dealt with a group of diseases, prevalent among sheep, of a nature closely resembling tetanus. The object of the paper was to call attention to the "relationship existing between these diseases of the sheep and many obscure diseases of man," and to the fact that these diseases of the sheep are caused by specific bacilli, whose habitat is the lumen of the intestine, but which, at certain periods of the year, pass through the wall of the bowel and are found in the peritoneal liquid but in no other part of the body. The result of their activity is the liberation of toxins which, when absorbed, produce in the sheep symptoms of a tetanic nature. The disease called "louping-ill" or "trembling" was used by Hamilton as the type of the group.

The points in that paper which have chief bearing upon the subject of post-operative tetanus are:

1. The similarity of these diseases in the sheep to tetanus.
2. The mode of entry of the bacilli.
3. The seasonal prevalence.
4. The geographical distribution.

1. The similarity of louping-ill and tetanus is most striking. The likeness is not only seen in the characters of the bacillus which produces the disease but also in the symptoms.

Of the bacillus Hamilton says "it is a large, coarse-looking rod, sometimes elongating into a thread, or it may be, a chain of rods. Its dimensions, like all the members of the group, vary considerably. The ends are rounded, and it is possessed of feeble motility. It has a considerable tendency to spore; the spore is located at its centre or at one end, and occasionally, especially after incubation in its native liquid, it assumes a drumstick configuration, indistinguishable from that of the *Bacillus tetani*."

Of the symptoms he says: "There are cases which assume quite a tetanic character. In these the muscles are in a state of rigid spasm, while, it is said, although I have never seen an instance of this in the natural disease, the muscles of mastication are in a like rigid condition, and, in most respects, the phenomena resemble those of idiopathic tetanus." "Certain instances of louping-ill have quite a tetanic character, and apparently tetanus itself can be aroused in the sheep by injecting subcutaneously the bacteriolysed organism of the disease."

2. The Mode of Entry of the Bacilli.—"On examining the carcass in this disease one of the most notable features is the absence of lesion which might serve to localize the peccant agent in any particular organ." "The abdominal cavity, as a rule, contains an excess of serous liquid, but this is not always the case." Sometimes the liquid is thick, muddy-looking, and it may be, tinged with blood, while at other times it is quite clear and limpid, or, at the most, a delicate coagulum separates from it. "In no case have I seen peritonitis or pleurisy accompany the disease, and hence the conclusion seems inevitable that the organism which causes it is not possessed of inflammatory tendencies." "The changes may be met with along the course of the intestine, but with this exception all the viscera may seem to be quite healthy. Nor have I seen any

evidence of meningitis or other disease of the central nervous system. The microscopic examination of the natural liquids or of the organs of the body proves equally disappointing. Thus the blood is free from any micro-organism which can be detected microscopically, and when cultivated aerobically or anaerobically remains equally barren. The cerebro-spinal liquid and nerve centres are devoid of any parasite which might be taxed with a causal relationship to the disease." "On microscopic examination of the turbid peritoneal liquid it was found to be teeming with a large, coarse-looking rod organism having a great tendency to spore, while in the case of that which was clear and limpid not a bacillus was to be detected. On incubating the clear peritoneal liquid, however, in sealed tubes, I found invariably that in the space of twenty-four hours it became turbid. On examination of the liquid microscopically it was now found to be swarming with the same large sporing rod present in the liquid which was turbid."

"Not only in the case of louping-ill but in that of all the other members of the group the intestine seems to be the portal through which the organism gains entrance, and the fact that the peritoneal cavity contains it more than any other cavity or any organ in the body is thus readily enough explained."

3. Seasonal Prevalence.—"One remarkable feature of these diseases is that they occur periodically—that is to say, at stated times of the year. Certain of them, such as braxy, prevail in the autumn and winter months, while others, and more particularly louping-ill, are diseases of the spring and summer months, the middle of April to the middle of June. All of them tend to vanish during the summer. They show themselves almost to a day, each in its season, and vanish quite as regularly and mysteriously."

4. Geographical Distribution.—"They prevail only in certain districts, and mainly along the West Coast and southern counties of Scotland and the northern counties of England, while the East Coast of the whole of Great Britain may be said to be almost exempt from their ravages. Draw a straight line from the North of Scotland down to the South of England, and you practically separate the infected districts from the non-infected." "The valley of the North Tyne is one of the most severely smitten areas."

With regard to tetanus itself, Professor Hamilton says:

"In the case of tetanus, the symptoms are induced by the absorption of a toxin secreted by the tetanus bacillus. The organism exerts its evil influences only when introduced into a wound: when administered by the mouth it is apparently harmless. So universally is the organism distributed in Nature, that we must be constantly swallowing it, and yet no ill-effects follow."

"There is a variety of tetanus which is known as 'idiopathic,' mainly because we know nothing of its pathology, and in which there is an absence of any wound of the surface, or other apparent point of entrance. It has always been assumed that the organism inducing this idiopathic variety is the same as that occurring in the traumatic form. In view, however, of the disease, 'louping-ill' of the sheep, being so closely allied with tetanus, both with regard to the organism producing it and in the character of the symptoms occasionally evoked, I would be inclined to pause before admitting the truth of this allegation. May it not be a disease caused by an organism of the same class as that producing louping-ill, but intestinal in its habitat, as are the organisms instrumental in producing all the members of this class of diseases of the sheep? and may it not happen that it is a common inhabitant of the intestine, but that only in certain susceptible individuals gets over from the channel of the bowel into the blood, becomes bacteriolysed, and so allows the toxins bound up in its protoplasm to escape, these again acting on the nerve cells with which they have a combining affinity?"

"Tetanus of the newborn is also a form of the disease of whose pathology we have no conception, and I would go so far as to suggest that it may be the result of the action of such an intestinal anaerobe to which the infant has not as yet become immunized."

When one recalls the fact that all the catgut which is used by surgeons is obtained from the intestine of the sheep, the bearing of Professor Hamilton's paper upon the subject of post-operative tetanus becomes apparent.

The questions arise:

1. Is it true tetanus, or some other member of the group of diseases so common amongst sheep, by which patients are apt to be attacked after undergoing surgical operations?

Answer may be sought in an investigation of the symptoms of those who have suffered, and in an examination of the bacilli from those cases in which cultures of material from the patient have proved the presence of drumstick organisms.

As to the Symptoms.

We surgeons who attended any of these 21 cases had no doubt in our minds that the patients suffered from true tetanus, but whilst accepting these diagnoses, we must bear in mind the fact pointed out by Professor Hamilton that the symptoms of all the group of diseases of which louping-ill is the type, are hardly to be distinguished from tetanus.

In the case of idiopathic tetanus, he makes the definite suggestion that it may not be true tetanus, but a disease caused by an organism of the same class as that which produces louping-ill.

As to the Bacilli.

The catgut used at the operations in 14 of the cases was examined bacteriologically, and bacilli were found in the cultures in four instances. Bacilli were found in the cultures from the ovarian pedicle in another case.

In one case the report from the bacteriologist was as follows: "From the cultures of this sample of catgut we have isolated a large anaerobic bacillus, of which some of the individuals show large terminal spores, giving to the rods the drumstick appearance characteristic of the *Bacillus tetani*. It will not be possible to find proof of the specific nature of this bacillus without animal inoculation." "Note.—We were not authorized to have an animal experiment made, so there was no further investigation."

In 2 cases the reports are to the effect that "a bacillus allied to the tetanus bacillus was found, but that experiments upon animals were negative."

In another case I have only the statement that tetanus bacilli were found in the catgut, which was "shop-prepared."

In another case no organisms were found in the catgut, but "the cultures from the ovarian pedicle, though 'resembling' tetanus bacilli, were negative in experiments upon animals."

The only answer, therefore, which can be given to the question whether or not it was true tetanus from which these patients suffered, is, first, that the symptoms were characteristic of a group of diseases closely allied to tetanus; and, secondly, that in the catgut used at four of the operations and in the pedicle from another case, a bacillus was found resembling in appearance the tetanus bacillus but similar to the bacilli of a group of diseases allied to tetanus, and that proof of its being the tetanus bacillus failed in experiments upon animals.

2. Is the Infection Conveyed by the Catgut?

The fact that catgut was used in every one of these cases is the most striking as well as the only apparent common feature. It tempts one to blame catgut offhand, but careful inquiry suggests some doubt.

At the outset we are met with a difficulty. If we blame catgut as the vehicle by which the disease is introduced, we assume that the tetanus bacilli are wrapped up amongst the strands of the ligature, in which they probably existed at the time of the manufacture of the catgut, and that they are liberated during the process of its absorption. Now catgut is made from the intestine of the sheep, which "is not an animal liable to tetanus as we ordinarily understand the disease." Therefore it would appear more probable that there should exist in the catgut the bacilli of one of the other members of the tetanic group of diseases, which are known to infect the intestine of the sheep, rather than the bacilli of true tetanus.

I have made inquiry of most of the business firms who supply catgut to the large hospitals in England, Scotland, and Ireland, and, with one exception, they tell me that the raw catgut is procured from Germany. If it is the vehicle of infection, tetanus should occasionally follow surgical operations in all parts of the United Kingdom, because catgut is used very largely by surgeons all over Great Britain. In most of the great hospitals, both in London and the Provinces, and in many private practices it is almost the only material which is used for ligatures, and yet the occurrence of post-operative tetanus appears to be unknown in the South of England and in the Eastern Counties.

Of the 21 cases—

- 11 occurred in Northumberland
- 6 occurred in Ireland
- 2 occurred in Scotland
- 1 occurred in South Shields
- 1 occurred in Manchester

That is to say, they were found in the same geographical area as that in which the tetanic group of diseases in the sheep is prevalent.

Professor Hamilton's observation about the geographical distribution of "louping-ill" applies exactly to the distribution of these cases of post-operative tetanus. It is

impossible to believe that German catgut, if infected with bacilli, will produce a disease when used in the North of England, in Scotland or in Ireland, and yet be innocuous when used in the South of England or in the Eastern Counties.

In view, therefore, of the common source from which catgut is obtained, its general and widespread employment, and the irregular geographical distribution of these cases of post-operative tetanus, it does not appear probable that catgut is the carrier of the bacilli which produce the disease. Enough has been stated to show that there is a legitimate doubt, first, as to whether the disease which we have been calling post-operative tetanus is really tetanus, and secondly, as to whether the disease, whatever it may be proved to be, is conveyed by the catgut.

On the supposition that it is not tetanus but some other member of the group of diseases so prevalent amongst sheep, it is interesting to see how far the facts of these 21 cases agree with the essential points laid down by Hamilton as characteristic of those diseases.

We have seen that the symptoms are of the same tetanic character and that the bacilli are indistinguishable; also that the geographical distribution is identical. There remain the seasonal prevalence and the mode of entry of the bacilli.

With regard to seasonal prevalence, of the 21 cases

occurred in January		3 occurred in July	
1	" February	2	" August
1	" March	3	" September
2	" April	1	" October
2	" May	2	" November
1	" June	None	" December

The Mode of Entry of the Bacilli.

When considering this point a feature of the cases presents itself which is almost as striking as is the fact that catgut was used in all—namely, that of the 21 cases, 19 followed operations in which the peritoneal cavity was opened. It cannot surely be a coincidence that over 90 per cent. of the operations involved the peritoneum. At the Royal Victoria Infirmary in the year 1907, as nearly as I can estimate, 4,377 operations were performed which required the making of an incision and the use of ligatures. Of these, 1,472 involved opening of the peritoneal cavity, and 2,905 were upon other parts of the body. That is to say, there were twice as many operations upon other parts as there were within the peritoneum. This may be taken as an average proportion of peritoneal to non-peritoneal operations. If, then, catgut were the guilty agent of infection one would expect to find that a majority of the cases of post-operative tetanus occurred after these other operations rather than after those upon the peritoneum, especially when one remembers the large amount of catgut which is left in the wound of such an operation as that for the removal of enlarged glands from the neck as compared with the small amount used in the radical cure of an inguinal hernia, or in an operation for the removal of an ovarian cyst. It would not be surprising to find that any of the bacilli of the spore-bearing nature referred to, so common amongst sheep, are frequent inhabitants of the human intestine, nor to find that the patient is himself the host of the bacilli at the time of the operation, because the gathering ground of the drinking water used in the districts from which these 21 cases have been collected is largely covered by sheep farms. This is especially true of Northumberland, in which county the majority of cases have occurred, and in which "louping-ill" is prevalent. Such an explanation would appear to hold good for sporadic cases, such as my own, which occur without any ascertainable cause, and in which the catgut is proved to be sterile.

It is possible that the catgut may have become infected with bacilli after its importation into the counties in which post-operative tetanus has occurred, but this would apply also to any other material, such as silk or linen thread, used in the same district. I do not know of any case having occurred in which any other kind of ligature than catgut has been used. Too much stress must not, however, be laid upon that observation, because it may be due to the fact that catgut is used almost universally in Northumberland to the exclusion of silk and other ligature materials.

Between some of the cases there appears to be a direct connexion.

In one house 2 cases occurred in the course of eight weeks.

In another house 4 cases occurred as follows: One in October, one in June, one in July, one in August. In that house the water supply from a new cistern was suspected, and an anaerobic bacillus was developed from the water; since attention to that no further case has occurred. Although a careful investigation was made, no bacilli were found in the catgut used at any of the four operations. They were all abdominal operations.

In the Royal Victoria Infirmary five abdominal sections were performed by the same surgeon in the course of one morning. The third operation was for gall stones, and the fourth for appendicitis. Both of these patients developed tetanus, and the gall-stone patient died. None of the other 3 cases developed symptoms, although catgut from the same store was used in all the cases.

I have ventured to publish this list of cases, large as it is when viewed as a series of surgical calamities, but small when used for the purpose of generalization, and to make the foregoing remarks, in the hope that others who can throw light upon the subject may be induced to do so.

It is a matter of the most serious nature. Not only is it horrifying to think that a patient should suffer from a deadly disease after a simple operation, such as the radical cure of an inguinal hernia, but it is a matter of the utmost importance that we who used catgut should know whether we will be justified in reverting to its use. It will be a great misfortune if catgut should be proved to be the agent, because it is without any doubt the ideal ligature and suture, having advantages over all other materials. If it is the guilty agent, it would appear as if its use must be discarded altogether, because, judging by the variety and thoroughness of the means which were employed in the sterilization of the catgut in many of these cases, it seems to be impossible to destroy the spores without at the same time ruining the ligature.

The methods were various, and I am unable to give the exact process followed in each case, but in my own cases it was as follows: Raw catgut was wound upon small glass reels and placed in ether for twenty-four hours. From this the spools were transferred to fresh ether for another period of twelve hours. They were then placed in a 1 in 1,000 solution of biniodide of mercury in methylated spirit for twenty-four hours, being then transferred to a fresh similar solution, in which they were kept for several days before being used. I had the catgut thus prepared bacteriologically examined on several occasions, and it was always found to be sterile.

In several of the other cases the catgut was prepared by boiling in absolute alcohol at 212° F. for one hour after it had gradually been raised to boiling point.

SUMMARY.

From the foregoing observations I have drawn no conclusion, as they do not appear to justify it, my object in writing this paper being to elicit from others information which may lead to a definite solution; but I would like to give a short summary of the facts and to offer a suggestion.

Hamilton pointed out that there is a group of diseases amongst sheep the symptoms of which are closely allied to tetanus and the bacilli of which cannot be distinguished from those of tetanus.

In these diseases the bacilli are normal inhabitants of the sheep's intestine, but at certain periods of the year they pass from the lumen of the bowel into the blood, where they become bacteriolized, and the liberated toxins give rise to the symptoms of the various diseases.

During these seasons the bacilli are found in the peritoneal cavity and in no other part of the body.

These diseases are endemic in certain parts of the British Isles.

The 21 cases of post-operative tetanus have occurred only in those districts in which the tetanic group of sheep diseases is endemic.

More than 90 per cent. of the cases of post-operative tetanus followed operations in which the peritoneal cavity had been opened.

Bacilli resembling tetanus bacilli have been found in the

remnant of catgut used for ligatures in 4 cases and in the ovarian pedicle in 1 case, but confirmation of the suspicion that those bacilli were tetanus bacilli has not been forthcoming.

The catgut used at these operations was obtained from the same source as that which is used in the South of England and the Eastern Counties.

I would suggest:

1. That the disease which we call post-operative tetanus is not tetanus at all, but one of the sheep diseases.
2. That it is not introduced by the catgut.
3. That the patient is, at the time of the operation, the host of the bacillus.

4. That we must look upon these cases of post-operative tetanus as cases of idiopathic tetanus, accepting Hamilton's suggestion that idiopathic tetanus is not true tetanus as we ordinarily understand the disease. By that I do not assume that these patients would have developed tetanus had no operation been performed. I would rather account for the sequence of events by supposing that the disturbance aroused by the opening of the peritoneum at the operation was of such a nature as to favour the activity of bacilli which, possibly, would have remained dormant had no operation been performed.

That the mere opening of the abdomen can affect the interaction of a patient and bacilli already present in the peritoneum is frequently demonstrated in cases of tuberculous peritonitis, when a small incision, without any other interference, is followed by immediate improvement of the local condition and ultimate complete recovery.

It may be suggested that the ligatures are infected at or before the time of the operation—that is to say, that post-operative tetanus is the consequence of faulty surgical technique. During the past five years some 350 patients have had loose cartilages removed from the knee joint, at the Royal Victoria Infirmary, without mishap. This, I believe, is a sure test of the efficiency of any surgical method, and would point to the sterility of the catgut, unless we are to believe that all other germs than tetanus bacilli may be destroyed and yet the latter may remain unaffected.

From such facts and observations as I have brought forward, it will be seen that many questions arise which I am quite unable to answer. As I have said before, this paper is written with the sole object of gathering information. Twenty-one cases are far too small a number to warrant the drawing of any conclusion. For instance, I have failed to find any cases of post-operative tetanus in the South of England, in spite of some diligence, and I have laid some stress on the identical geographical distribution of these cases and the group of sheep diseases, but it may well be that there have been many such cases in the southern counties. If that be so, my argument fails.

In view of the almost universal use of catgut, it appears to me to be a duty to publish my cases, and I hope that others who have had the misfortune to encounter similar experience may be induced to do the same. The problem as to whether the disease is really tetanus is interesting, and suggests many collateral inquiries. That, however, is not a subject with which I am able to deal, it being a matter for bacteriologists. The central point is to find out whether the infection, whatever it may be, is conveyed by the catgut, and I am not without hope that catgut may be acquitted.

FRACTURE OF THE THIGH IN THE NEWBORN.

By J. L. T. ISBISTER, B.Sc., M.B., Ch.B., ADELAIDE, NORTH SYDNEY, NEW SOUTH WALES.

CONSIDERABLE interest has lately been aroused in regard to the treatment of fracture of the femur in the newly-born child. Various means are suggested for treating this difficult fracture, but, with the exception of Credé's original method, they are all based on the supposition that both extension and traction are necessary.

Credé recommended binding the limb in a flexed position to the abdomen. Unfortunately, this does not invariably give the best result, and an unsatisfactory union is a difficult thing to rectify. The unsatisfactory cases possibly result from the restlessness of the child, and a heaving abdomen which is sometimes distended

and sometimes relaxed. But the principle of flexion is correct, and the idea is supported by the fact that the newborn child naturally adopts the flexed position for some few weeks after birth, and always sleeps in this posture. On occasions the legs are stretched out, but they always return more or less to the flexed position. It is the child's position *in utero*, and we cannot expect it to alter suddenly. Hence we are right in assuming that flexion is the position of greatest muscular relaxation.

If further proof were necessary, it is to be found in a rapid examination of the fracture under an x-ray screen. This must be done very rapidly in a very dark room, for Roentgen rays can do small children no good. With the child in a horizontal position, the thigh is gradually flexed, and the fragments can be seen to come into line and apposition with each other when the limb is all but touching the abdomen. Professor John Cleland, Professor of Anatomy at Glasgow, says that:

When the spinal column is in its natural position in the newly-born, the hip-joint is in full extension when the femur is at right angles to the spinal column. If, then, the thigh be pressed down so as to bring it in a line with the trunk, the change is effected not at the hip-joint, but in the lumbar region by turning the pelvis backwards. This is not a natural position in the newly-born.

He further says:

"What happens naturally is up to the time of birth the cervical, thoracic, and lumbar parts of the vertebral column present a continuous concavity forwards.

At birth the head is thrown back and lies naturally on the mother's arm, the cervical convexity thus making appearance. When the child begins to try to walk it throws its pelvis back, and produces the lumbar convexity, and the stretched thigh is thus made to revolve a quarter of a circle or a right angle.

These observations he confirms by anatomical dissection. Surely this supports Credé's flexed position and the view that traction is not necessary. Hence, an apparatus that will keep the fractured limb flexed, and just a little off the abdomen, is all that is necessary.

The accompanying figure illustrates the splint. Roughly speaking, it is shaped like the letters Z O, the latter being attached to the Z at a right angle at the lower right-hand corner. The foot is not included in the splint, which reaches only to the tendo Achillis. A small trough-shaped piece takes the calf, and the trough is continued up the back of the thigh—two-thirds of the way is enough. A small bar clearing the buttock is attached at the upper end to a 2 in. wide loop surrounding the abdomen. The end of this loop or belt is fixed in a slot, so that the diameter can be readily altered. The whole is made of aluminium, and weighs, unpadded, 1½ oz. The splint is best padded with a few layers of lint, soaked in olive oil to prevent contamination, which at the most is but slight. Aluminium is not only very light, but practically pervious to x-rays, hence the fractured ends can be seen with the splint applied to the limb.

The sound limb, as a rule, is placed by the child in the same position as the fractured. This is an advantage, as one limb supports the other and makes it easier for the mother to hold and nurse the child. In fact, the child can be nursed just like an ordinary child, can be taken out into the open air, and need not be kept in its cot; it may also be taken into bed by the mother at night time. All

cumbersome appliances become unnecessary. When the child is clothed there is nothing to indicate the presence of the splint, and by the mother's arms the slight additional weight passes unnoticed.

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF RHEUMATIC OR RHEUMATOID ARTHRITIS BY RADIANT HEAT AND CATAPHORESIS.

I HAVE no doubt as to the efficacy of the American apparatus, with its 500 candle-power lamp, referred to by Dr. Bailey (p. 13) and by Dr. Gamlen (p. 371), but, like Dr. Gamlen, I am uncertain as to which of the rays it emits one must attribute its superiority, or whether, indeed, such superiority be due to any special rays, or only that by its use free ventilation of the part under treatment is ensured and moist heat avoided. I have often noticed that during its application patients will perspire over the body generally, while the part on which the rays are directed remains dry and becomes red and mottled.

I always employ cataphoresis, but whether its good results are due as much to the introduction of iodine or other ions as to the passage of the current itself I am sceptical. I have used solutions of iodide, usually in the form of KI and have also used solutions of NaCl, and so far I cannot find a marked superiority of the one over the other. Whatever substance be used it is ionized through the skin, but I believe that the portion that reaches the region of lymph channels and blood vessels is at once swept away into the general system; and I question, in the case of a given joint, when two electrodes, moistened with the solution which it is desired to introduce by ionization, are placed one on either side of the joint, and the necessary current passed, whether the ions thus introduced directly reach the joint itself, or even if some do find their way there, whether their number is sufficient to have a therapeutical effect. I grant that they get into the circulation, but that is not the point.

This is no place to discuss at length the action of a constant current on living tissue. Suffice it to say that there is an alteration of metabolism and an improvement in nutrition, and it is this very condition of malnutrition that we are trying to combat.

I believe that in a large number of cases the joint changes are due to a trophoneurosis set up by an absorption of toxins from the alimentary tract. I therefore endeavour to put my patients on a suitable diet and course of medicinal remedies such as will tend towards the maximum of nutrition and the correction of any gouty or other tendencies, and I further order a systematic lavage of the large bowel on the Plombière system.

LOSS OF HAIR IN EXOPHTHALMIC GOÏTRE.

ONE of the symptoms of exophthalmic goitre which is little mentioned is the loss of hair. If patients are carefully questioned on this point, I think it will be found in most cases, particularly in women, that this symptom is present. That has been my experience. One case in particular, of which I have the notes, was instructive:

The patient, a young lady about 23, complained of "palpitation" and weakness. She was anaemic, and a haemic murmur was recognized at the base of the heart. The thyroid was not enlarged, and there were no nervous symptoms. Under tonic treatment she recovered.

About two years afterwards the patient consulted me again, her chief trouble being loss of hair, which was going on rapidly. She complained of being easily upset and worried, and attributed this to the alopecia. Although anaemic she otherwise felt well. Both appetite and digestion were good, and she slept well. She was able to bicycle, but of late palpitation of the heart had made this difficult. She had been under medical treatment, but neither iron tonics nor local applications to the hair had done any good. I asked if any enlargement in her neck had been detected, and was told it had not. One medical man, whose name was mentioned, I feel sure would have certainly diagnosed the disease had the thyroid been enlarged or the other symptoms been present when he saw the case.

When I examined the patient the right lobe of the gland was increased in size, the eyeballs were slightly prominent, and

von Graefe's sign was obtained. Stellwag's and Moebius's symptoms were not present. The loss of hair was distressing. In addition to large patches of alopecia at the back and top of the head, the forehead became affected, and later the eyebrows and eyelashes commenced to fall off. The anaemic condition increased. The patient was of slender build, and emaciation was not marked. The hair was falling off so rapidly that I decided she should see a dermatologist in consultation. His opinion was that the alopecia was due to exophthalmic goitre and to no other cause.

With regard to treatment: at the time of which I write radogen was unknown. Thyroid gland tablets were first given, but I do not think they did any good, nor did the symptoms increase under their administration. Next thymus tablets were tried, without effect. Iodine was applied over the gland, and I think it was of use in preventing increase in size; it may, perhaps, have reduced it. Palpitation was treated with tincture of digitalis at first; the symptoms were relieved, but although the drug was exhibited for some little time it was evident that it had no effect in quieting the heart effectually. Tincture of strophanthus was next tried, and in a short time the pulse fell from 120 to 80.

I see that in vol. iv of the *System of Medicine* (Allbutt and Rolleston) Dr. Hector Mackenzie is of opinion that digitalis and strophanthus are of little or no use for palpitation in Graves's disease. Professor Murray of Newcastle-on-Tyne also thinks little of them. In the *Manual of Medical Treatment* (Yeo, Crawford, and Buzzard) I find "several trustworthy observers testify to strophanthus" in doses of 5 minims three times a day. In my patient strophanthus certainly succeeded after digitalis had failed.

As regards the administration of thyroid tablets for simple goitre, I can confirm the results of Dr. Murray and others. In a case which I saw last year—the lady having lived nearly all her life in Worcestershire—I tried the method recommended, I think, by Captain McCarrison, I.M.S., of giving thymol. It was continued for some weeks but had no appreciable effect. Since then thyroid extract in tablet form has been given. The gland has much diminished in size. The patient has removed to a more bracing place, and I am informed her health has much improved in consequence.

CONGENITAL DISLOCATION OF THE LENS.

THESE two cases, occurring in a brother and sister, are interesting chiefly because the displacement is atypical and is different in each child, and also because the maternal grandmother had the same condition. Unfortunately she was not available for examination.

CASE I.—Frank McB., aged 9. His mother stated that the grandmother also had "dislocated lens." The boy's eyes had the normal appearance except for tremulous iris.

V. = $\frac{20}{20}$ e.e. + 12 D.sph. = $\frac{20}{20}$. Near vision = 2 D. Snellen; not improved by glasses. The boy uses his own lens in near vision. Both lenses were dis-

located up and to the left, leaving slightly more than half the dilated pupil uncovered. In the left eye were a few faintly visible membranous filaments running downwards and inwards from the lens, waving slightly on movement of the eye. There was nothing else abnormal in either eye, and there were no other congenital abnormalities.

CASE II.—In Nora McB., aged 5, the sister of Case I, the right lens was dislocated downwards and outwards, covering three-quarters of the dilated pupil. The left lens was dislocated down and out, covering less than half of the dilated pupil. No other abnormalities were detected.

In both children the visible edge of the lens is part of a perfect circle.

Sydney, N.S.W. Assistant Ophthalmic Surgeon, Sydney Hospital.

DESTRUCTION OF SWEAT GLANDS BY THE ROENTGEN RAYS.

MAJOR F. J. W. PORTER's interesting memorandum in the *BRITISH MEDICAL JOURNAL* of January 30th, p. 277, giving

an account of a method of treating excessive axillary sweating by operation seems a very drastic method when a much less severe treatment, with no operation, attains the same result. My attention was called four years ago to the fact that the effect of x rays on the sweat glands was to destroy them. The first case that came to my notice was that of a joiner to whom I applied x rays for the treatment of a tuberculous condition of the skin over the hip. Some months after he was cured he volunteered the information to me that he no longer perspired on the part of his body on which the x rays had fallen. Since that case I have noticed the same condition in many others in which I have applied x rays for the treatment of tuberculous glands in the neck. Children lose permanently not only the downy hairs on the side of the neck by this treatment, but also the sweat glands. To destroy the sweat glands six efficient x-ray treatments is all that is necessary—one treatment a month, giving at each sitting the maximum dose that the skin will stand. The sweat glands are the most readily affected of all the glands in the body by the x rays, and the most readily destroyed. By efficiently x-raying the axilla in the way described, not only are the sweat glands destroyed but also the hairs of the axilla.

St. Bartholomew's Hospital.

ANEURYSM OF THE HEART IN WOMEN.

CARDIAC aneurysm is rare in the male, and even more so in the female. On that account it has been thought that this case is worthy of record.

J. D., aged 57, the widow of a seafaring man, had had no children, and there was no history of miscarriages. She had been a drinker of spirits to excess for some years, and was admitted into Newcastle City Asylum suffering from depression. During the eleven years of her life there she had various skin lesions, which were cured by potassium iodide.

On admission to the asylum a mitral murmur was noticed to be present. Though always a rather feeble-looking woman she never made any complaint of pain or distress in the cardiac region. She nevertheless had occasional syncope attacks. A fortnight before her death she fainted three times in one day, and was consequently put to bed. Nothing abnormal was detected in the heart sounds; the pulse was small, regular, and accelerated. She now had considerable pain and a feeling of tension over the heart.

During the last week of her life a considerable pleural effusion developed. She became unconscious, and remained in that condition three days before she died.

The post-mortem examination showed a considerable pleural effusion, nutmeg liver, and cirrhotic kidneys. The heart weighed 540 grams. The aneurysm was situated in the middle third of the outer wall of the left ventricle; it was the size of a pigeon's egg. It contained a quantity of semi-organized clot. The myocardium covering the aneurysm was thinned and was fibrotic. Immediately above the opening of the sac the heart muscle had undergone distinct interstitial changes.

In all probability the condition was the result of a gumma, but it is difficult to say why the secondary lesion followed, as the woman was of sedentary habits, and never exerted herself.

FATAL HAEMATEMESIS DUE TO PERFORATION OF THE THORACIC AORTA BY A FISH BONE.

(By Sir THOMAS OLIVER, M.D., LL.D., D.Sc., F.R.C.P.,
Physician to the Infirmary.)

ON December 20th, 1908, at 11.30 p.m., M. C., aged 40, married, was admitted, having at 5 a.m. suddenly vomited a large quantity of blood. She was four months advanced in pregnancy and had suffered much from sickness, but as this was usual to her when in that condition little attention was paid to the circumstance until, on December 20th, there had been several vomitings of blood.

On admission she was extremely blanched and looked ill; she was semiconscious and restless. The pulse was rapid and feeble and the temperature subnormal. There was no abdominal tenderness and no rigidity; there was extreme thirst.

The patient was kept warm in bed, morphine was injected hypodermically, saline and nutrient enemata were alternately administered with stimulants, all of which, however, were not retained, for part was returned; black, tar-like stools were passed. When I saw her on the following morning she was quite conscious but extremely feeble; the pulse was scarcely perceptible. There was no pain complained of, even on palpating the abdomen. She was too ill to be examined carefully. In the afternoon she died.

Immediately previous to the *post-mortem* examination being made by my house-physician, Dr. David Ranken, to whom I am obliged for the notes of the case, the husband of the woman casually mentioned that his wife had swallowed a fish bone, that of a ling, ten days previously, and that she had complained of pain in the region of the stomach. No importance was attached to the circumstance either by the patient or her relatives.

On opening the abdomen the intestines were observed to be dark and somewhat distended. The stomach, too, was moderately distended, and on being slit open was found almost filled with dark blood. Careful examination of the mucous membrane failed to reveal the presence of ulcer, abrasion, or congestion. The cardiac end of the stomach, however, was discoloured. In the oesophagus, at the level of the transverse and descending portions of the aorta, three small ulcers with congested borders and deeply excavated floors were found. These ulcers extended along the length of the oesophagus for a distance of $\frac{3}{4}$ in. Beyond this point the mucous membrane was injected and in places excoriated. On probing the ulcers a definite opening was found in the lower part of the largest ulcer which communicated with the thoracic aorta, the lumen of the connecting canal being as large in diameter as that of a small probe. No fish bone was found, although the whole of the gastro-intestinal tract was carefully searched, but under the circumstances, even if present, it would have been extremely difficult to have detected a fish bone. The heart was healthy. On examining the aorta a small irregular perforation was found on its inner surface, which corresponded in level with the ulcers on the oesophagus. Passed into this opening the probe readily emerged from the floor of the largest of the oesophageal ulcers.

Fatal perforation of the oesophagus and aorta by fish and rabbit bones is not unknown; indeed, the cases are probably more common than we believe, so that where the history of a patient having swallowed a bone is not given and there are conditions in existence at the time which of themselves might give rise to haematemesis, the real cause of the fatal vomiting of blood may be easily overlooked.

W. G. SMITH, M.D., President, in the Chair.

Gas in the Stomach.

In a paper on this subject Dr. CAHILL said the term "fermentation" was mainly applicable to the decomposition of carbohydrates, and "putrefaction" to the decomposition of proteids and fats. After classifying the causal factors in the production of gastric gas under various heads, he put in a plea for the more careful investigation of the causes of "flatulency."

The PRESIDENT took exception to the distinction drawn between fermentation and putrefaction. He looked on putrefaction as a mere accident of decomposition; it was simply fermentation *plus* smell. He thought the term were not susceptible of accurate definition in the sense in which Dr. Cahill used them. He was not hopeful of the possibilities of intestinal antiseptic treatment, as none of the things used had come up to expectation.

Dr. COX said it was a rare thing for an amount of air capable of causing trouble to get into the stomach by swallowing. He thought the troubles must be looked for within. They had seen cases where mental trouble or sudden shock had led to gas being formed by a process which was probably neither fermentation nor putrefaction, and in which a great amount of misery and depression was relieved by the expulsion of gas. In such cases he thought the subjective sensations were as much to be accounted for by the depression associated with mental causes as by poisoning of the blood by the by-products of digestion, or the uneliminated products of liver digestion.

Sir JOHN W. MOORE said that people with bad teeth, who could not masticate their food, swallowed with it very considerable quantities of air. They were familiar also with the connexion between cardiac and vascular lesions and gas in the stomach. It was exceedingly hard to disinfect either the stomach or intestines, but symptoms could often be relieved by attention to the toilet of the mouth.

Dr. CAHILL, in reply, said the distinction drawn between "fermentation" and "putrefaction" was only for clinical use, seeing that the processes exhibit no absolute line of demarcation. The stress laid on air swallowing by Sir John W. Moore was in agreement with the observations of the writer. An illustrative case of inflammable gas (CH₄) was quoted, a parallel to that noted by the President from the work of Sir Henry Marsh.

Haematoporphyria.

Dr. PARSONS described the case of a woman who came under his care early in June suffering from diffuse abdominal pain, vomiting, and constipation.

The urine, on standing, became of a deep port wine colour. It contained neither albumen nor blood. Neither trional nor sulphonal had been administered at this time. After ten days the patient improved, and went away for a change. The symptoms, however, recurred, and she was admitted to hospital towards the end of June. Abdominal pain was present. Sleeplessness was pronounced, and she was given on four consecutive nights 15 grains of trional. The urine was of a similar colour to that passed early in her illness. Towards the end of the first week after admission she complained of severe pain in her feet, and on July 7th her arms were almost powerless, and she was so ill and feeble that she could barely move in bed. On July 10th the rectal sphincter was relaxed and she commenced to pass under her. A few days later swallowing became difficult, and death took place in a little over two weeks after her admission to hospital, and in less than seven weeks from the onset of her symptoms.

Specimens of the urine passed shortly after her admission to hospital, and a day or two before her death, were exhibited. They were of a rich port wine colour, and, though nearly three years old, were acid in reaction and showed no evidence of decomposition. Though haematoporphyrin was probably present, the red colour was not due to this substance, and the exhibitor considered that the term "haematoporphyria" applied to urine of this class was misleading.

LIVERPOOL MEDICAL INSTITUTION.—At a pathological meeting on April 1st, Mr. BICKERTON, President, in the chair, Mr. NIMMO WALKER read a note on the application of bacteriology to eye surgery. He described the methods of bacterial examination of the conjunctival sac in (1) cases of purulent discharge; (2) clean cases previous to operation. At St. Paul's Hospital this examination was the routine practice, and he strongly emphasized the value and necessity of such. He illustrated his remarks by cases, films, and cultures. Dr. E. GLYNN read a note on hepatic cirrhosis with adenomata and carcinoma in a man aged 49 years, who died after eight months' illness. He had had all the signs of cirrhosis and slight jaundice; latterly the liver had been enlarging. The liver after death weighed 119 ounces, and showed (1) multilobular cirrhosis of the right lobe, with circumscribed green "adenomata," and microscopically many bile-containing tubules; also diffuse white growths, resembling spheroidal-celled cancer infiltrating the portal vein and causing enlarged spleen. (2) There was marked compensatory hypertrophy of the left lobe, with a few "adenomata." There were no growths in other organs. Dr. HILL ABRAM and Dr. GULLAN referred to three or four similar cases with which they had met. One of Dr. Abram's cases was associated with secondary growths in the anterior mediastinum.

GLASGOW SOUTHERN MEDICAL SOCIETY.—At a meeting on April 1st Dr. DAVID LAMB, in a paper on *Anaesthetics*, said the best results were obtained by a selection of anaesthetics based upon an experience of them all; for those unable to obtain this experience he advised the use of a mixture of chloroform and ether (C_2H_5O), as being safer than chloroform and as easily administered. Troublesome rigidity of the abdominal muscles was apt to occur, especially in stomach, gall bladder, and deep pelvic cases. This could usually be overcome by taking time to get the patient well under before beginning the operation, by maintaining as deep an anaesthesia as was consistent with safety, and by as gentle manipulation as possible on the part of the surgeon. There were cases, however, in which it was impossible at any stage to obtain complete relaxation of the abdominal muscles. He had seen on several occasions dangerous cardiac failure from chloroform at the moment the surgeon was complaining of abdominal rigidity. Very deep anaesthesia in the early stage was not without risk, but for abdominal work it was necessary and justifiable. In minor cases light anaesthesia was sufficient, and he had never had any serious reflex troubles under these conditions. As regards delayed chloroform poisoning, the exact cause of this had not yet been definitely determined. No case should be included in this group unless the symptoms were characteristic and verified by *post-mortem* examination. Sepsis must always be excluded. In recorded cases no relation had hitherto been established between the depth or duration of the anaesthesia and this complication. Speaking of local anaesthetics and spinal analgesia in major operations, he summed up thus: When to the pain of the preliminary puncture and the "creepy" effect which at the least must be produced upon the patient by a consciousness of his surroundings was added the possible risks of the procedure (which were certainly greater than those of a general anaesthetic when administered by a skilled anaesthetist), it must be concluded that, though they were methods to which the patient and surgeon might become accustomed, the cases would require careful selection before the best possible results could compare favourably with general anaesthesia. As a rule, also, it must be much more satisfactory for a surgeon to deal with an unconscious patient when anything unlooked for occurs or when some doubtful question arises.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting on April 7th, Dr. P. BOOBYER, President, in the chair, Dr. A. M. WEBER, in a paper on *Ante-partum haemorrhage*, classified its causes under injuries of the genital tract, disease of the cervix or vagina, and separation of the placenta. The last cause he again subdivided into accidental or unavoidable according to the implantation of the placenta. All these causes were illustrated by cases, the author reviewing the treatment of placenta praevia and urging the value of antiseptic douching in addition to

the usual precautions against maternal sepsis. The paper was discussed by the President, Drs. J. H. THOMPSON, T. GERATY, W. THIBLES, A. J. SHARP, and W. B. BLANDY, and Dr. WEBER replied. Dr. C. H. CATTLE showed a woman, aged 29, the subject of diffuse *Scleroderma*, a sequela of influenza four years previously. The whole of the upper half of the trunk with the exception of the hands and back of the elbows was affected as well as the head and neck. Dr. F. H. JACOB showed the characteristic spectrum of *Methaemoglobinemia* occurring in an elderly patient as the result of taking phenacetin to excess; and also a skiagram of the pelvis and hip-joints in an obscure case of double abnormality of the cervix femoris. Dr. A. M. WEBER showed a heart with patent septum ventriculorum fatal at the age of 8 years in a boy; the kidneys from this case were also shown and were in a state of advanced pyelonephritis as the result of congenital stenosis of the meatus urinarius.

UNITED SERVICES MEDICAL SOCIETY.—At a meeting on March 10th, Colonel D. WARDROP in the chair, Major W. W. O. BEVERIDGE, D.S.O., R.A.M.C., gave a demonstration of some recent methods of *Sewage analysis*, including one devised by himself for extracting the total gases in sewage. He prefaced his demonstration by remarks on the importance of the fact that when a sewage effluent was mixed with a tidal water, the more or less complete absorption of the oxygen dissolved in the latter took place. It was therefore necessary, in the case of any sewage, to know its purity or the degree of putrescible matter present by ascertaining, on the one hand, the amount of dissolved oxygen present in the sewage, and, on the other, by estimating the amount of oxygen it was able to take up, which might be termed its "oxygen appetite." In a tidal water, composed of equal parts of salt and fresh water, saturation might be represented by a volume of 6.20 c.c.m. of oxygen per litre, while the lowest limit to which it was safe to deoxygenate such a water was about 3.4 c.c.m. per litre. Below this point there would be danger of destruction to fish. Mr. N. BISHOP HARMAN demonstrated an apparatus giving a diaphragm test for *Binoocular vision*, founded on the fact that when a man with normal vision in both eyes looks through a hole in a diaphragm held at some little distance from him the eyes look crosswise through the opening, the left half of the field being viewed by the right eye, and the right half by the left eye. The test objects were of different natures—written type, pictures, or geometrical patterns for children and uneducated people, etc. The uses of the test were to determine the equality or otherwise of the vision in the two eyes, to determine the presence, absence, or any defect of binocular vision, to exercise the vision in squinting eyes, to detect malingerers feigning monocular blindness, and to demonstrate certain physiological phenomena connected with the perception and suppression of images.

Reviews.

BULLET WOUNDS OF THE VISUAL CORTEX.

Dr. T. INOUE,¹ of Tokio, who has had an unusual opportunity of studying the effects produced by bullet wounds upon the visual cortex, has recorded his observations in a volume written in German. By the employment of an exact method of determination of the position of the wounds in the brain and skull, and with the help of a cranio co-ordinometer, he has made a number of measurements, by which he claims that he has been enabled to represent the superficial surface of the occipital lobe in the cranium.

The author deals with the effects of the modern firearm on the skull and brain, and he remarks that, owing to the Russian bullets being of small calibre, they passed generally through the brain in a straight line, which could be determined mathematically if the point of entrance and exit were known; the injury to the brain structures corresponded to this line of transit.

The same bullets, however, may not always produce

¹ *Die Schöstörungen bei Schutzverletzungen der Korkischen Sehphäre.* Nach Beobachtungen an Verwundeten der letzten japanischen Kriege. Von Dr. Tatonji Inoue aus Tokyo. Leipzig: W. Engelmann. 1909. Sup. roy. 8vo, pp. 120; 39 figures, Taf. 2. M.6.)

penetrating wounds, but, owing to their glancing off the skull, the brain may be damaged beneath the point of reflexion. Most of the Japanese soldiers were wounded while lying on the ground in the position for shooting. The question arose after the war whether a pension should be granted or not; it was therefore necessary to ascertain the actual injury to sight, consequently the visual fields have in such cases to be carefully taken. Attention is also paid to the results of wounds due to splinters of shrapnel and shells. A number of cases are reported, a short but complete account of the main symptoms and anatomical conditions being noted. Excellent photographs of the head, showing the points of entrance and exit of the bullet, are given, also the perimeter charts which were taken in all the cases.

The author remarks that the patients often suffered with slight neurasthenic conditions, pain or peculiar sensations in the eyes or behind the optic bulbs, and he calls this condition "neuralgia optica," and considers that it may be explained by the law of peripheral projection of irritation; he assigns to it great importance for the diagnosis of lesion of the visual cortical area. Psychic blindness was observed in only one case; more often it was cortical blindness but always of a transitory character. The fundus was almost always normal; it was only seldom that there was optic neuritis and then it was but slight. The pupils reacted normally; the movements of the globes were often slow, but a true paralysis was not observed. It is of interest to note that in a case of lesion of the angular gyrus there was also a disturbance of the perception of depth, as is assumed to be present in monkeys after destruction of the gyrus angularis (Munk), and also, according to Monakow, such lesions in man will produce this result.

True alexia was not met with, although difficulties in reading occurred from the visual defects; there was sometimes disturbances of orientation. All possible forms of hemianopsia were observed, in the unilateral form there was preservation of macular vision on both sides, whilst in some cases of bilateral hemianopsia, superior and inferior, the dividing line passed through the point of fixation and there was no macular vision in the hemianopic fields.

The author deals with the projection of the visual area according to mathematical principles of corresponding surfaces; but in a review it is impossible to do more than recommend those interested to consult this valuable work. He is of opinion that the cortical visual field of Henschen is the principal visual area, but he considers that it is a little more extensive than Henschen admits. He would place it 1 cm. above and below the calcarine fissure.

However, it may be remarked that the striate area which corresponds to the cortical retina varies as regards its exact placement in different individuals; it may, as Elliot Smith and Mott have shown, come on to the external surface, although the superficial area of this cortex is practically the same in all individuals. For this reason the exact mathematical calculations made on the skull do not permit the same deductions to be made as to the extent, or even the exact location, of the cortical retina damaged in the same way that a careful microscopic examination of the brain in a fatal case permits. Consequently, although the methods adopted by Dr. Inouye are as near perfect as possible, we are unable to accept his deductions as conclusive in assigning to the posterior calcarine region the portion of the cortex concerned with macular vision, although his conclusions agree with the findings in the Schmidt-Laquer case. Most authorities would, however, accept the view of Monakow that clinico-anatomical evidence supports his deduction that there is a bilateral representation of the macula, although we are of opinion that its exact location has not yet been determined with accuracy.

This work has been carried out with great care, skill, and scientific accuracy, and should be of considerable value to army surgeons, ophthalmologists, and neurologists; it is based upon 28 cases occurring in 80,000 wounded soldiers, and offers another striking illustration of the efficiency of the Japanese medical service and the determination of their Government to utilize to the full extent scientific investigations.

HYPNOTISM.

In the recently-published sixth edition of Dr. MOLL'S *Hypnotism*,² being the translation of the fourth German edition, this standard work has been brought carefully up to date. Although, owing to the same and sober judgement which stamped the earlier editions, and the comprehensive basis on which their author worked, no revision of the plan or theory contained in the book has been required, very numerous additions have been made throughout the text, and several new chapters have been added. Among these are chapters on the general influences that hypnotism and suggestion have had on medicine, and a study of the salient features of psycho-therapeutics. Also the place and importance of suggestion in art, superstition, and ethnology are discussed much more fully than in the earlier edition, much invaluable information for those interested in folk lore and ethnology being given. The last section of the book, that dealing with occultism—animal magnetism, faith-healing, clairvoyance, telepathy, and spiritism—has been very considerably enlarged. This chapter contains a wide survey, and entirely just though temperate criticism of modern mystery-mongering in its popular forms, and also of the very diverse and subtler forms of the occult which have appealed to even such eminent men as Crookes, Wallace, and Lombroso, and to medical men like Schrenk-Notzing, Luys, and at one time Babinski. "When I come to look through the vast literature of occultism," Dr. Moll says, "I find that I am totally unable to discover even one series of experiments that carries with it a convincing proof of the reality of occultistic phenomena; nothing but casual observations or unchecked experiments."

As in former editions, the book opens with a careful account of the history of hypnotism, after which the author proceeds to such general considerations as the methods in use in inducing hypnosis; the relationship between hysteria and hypnotism; the influence of race, sex, age, etc., on hypnotizability, and general definitions. In reference to the growing trend of opinion that only the hysterical are hypnotizable, Dr. Moll considers that this mistaken notion, as he terms it, is partly due to the fact that most physicians have experimented with hysterical subjects only, and partly to a confusion of hysteria as theoretically conceived with the clinical conception of this disorder. If, as Mobius says, "all morbid bodily changes caused by ideas are hysterical," the psychological relationship of hysteria to hypnotism is apparent, but according to the author this theoretical conception of hysteria does not cover the cases clinically described as hysterical, a confusion of hysteria and hypnosis in consequence obscuring the whole question. After considering fully the symptoms of hypnosis; post-hypnotic suggestion; cognate states, such as sleep, dreams, etc., and the difficult question of simulation of hypnosis and its signs, Dr. Moll examines minutely and finally discards the various theories, psychological and physiological, which have been advanced to explain hypnosis. Particularly is he sceptical of physiological theories, including that which counts numerous adherents in France, based on the theory of sleep put forward by Duval, Lancette, and Pupin, which in its turn was founded on the now generally discredited "gemmular retractility" theory. All these theories, by their endeavour to explain mental processes by means of our present knowledge of the central nervous system, point, he states, to a disquieting tendency to over-estimate physiology. Dr. Moll's own explanation of hypnotic phenomena is only, he frankly admits, a limited one. The practical result of his inquiry is, perhaps, best summed up in his statement: "No new psychic law is to be found in hypnosis." One by one he takes the individual phenomena of suggestion: Voluntary movement; "positive and negative delusions of the senses"; *rapt*; the phenomenon of memory, and post-hypnotic phenomena; and shows how there are analogues of non-hypnotic phenomena. Beyond this explanation by analogy he does not consider it safe or even needful to venture, for "an explanation of hypnosis is not called upon to explain the real nature of the process by which an idea is aroused; that is a problem for psychology in general to solve." The

² *Hypnotism. Including a Study of the Chief Points of Psycho-Therapeutics and Occultism.* By Dr. Albert Moll. Translated from the fourth enlarged edition by Arthur F. Hopkirk. Contemporary Science Series. London and Felling-on-Tyne: Walter Scott Publishing Co., Limited. 1909. (Cr. 8vo, pp. 617. 6s.)

reader will therefore not find here any attempt at a uniform explanation of hypnosis, such being, in Dr. Moll's opinion, an impossibility; but, instead, fair and impartial criticism of over-venturesome and contradictory physiological theories and a cautious reasoning by analogy, which is meticulously careful never to overstep the limits of proved fact. In conclusion, it should be said that the legal aspects of hypnotism are not overlooked, and, as an evidence of the thoroughness with which this admirable work has been constructed, it may be mentioned that the bibliography, index of subjects, and index of names take up fifty-five pages.

The whole work is so packed with information that it is valuable if only for purposes of reference; it is characterized throughout by the moderation of statement which ensues when a calmly critical judgement is brought to bear on phenomena that appear marvellous to the eye of the uncritical, and has been excellently translated.

PATHOLOGY OF APPENDICITIS.

PROFESSOR ASCHOFF'S monograph on inflammation of the vermiform appendix³ has a subtitle denoting his purpose to employ histological descriptions in the solution of pathogenetic problems. Unfortunately the deductions he is bound to make from an "unbiased" interpretation of the histological findings lead him into a blind alley. What must have been the horror of his surgical colleagues, who have so generously placed all their material at his disposal, when they found him declaring his considered judgement against all surgical interference in a process unaided Nature manages so well that four-fifths of all those attaining the allotted span of years have endured it unscathed! Hence we have, between pages 102 and 104, something very like a *volte face*. Indeed, the author had only to look once more at the whole series of his very beautiful plates of microscopic appearances of the diseased organ in manifold states and stages to see that the riotous behaviour of his favourite diplococci, Gram-positive bacilli, and hypothetical spirochaetes must sooner or later let in the surgeon. Hence he comes suddenly but graciously to the concession that, if Nature does not seem to be successful in her attempts at dealing with an attack of appendicitis at the end of twenty-four hours, the wicked surgeon may be allowed a free hand. This, after all, is not far removed from submission to the dicta and deeds of the most hardened adherent of "early operation."

The value of the book lies, as might be expected, not in speculations as to pathogeny based on one set of data only, but in the painstaking care and industry with which serial sections of innumerable appendices, normal and abnormal, fetal and adult, have been examined and reproduced. A strong case is made out for enterogenous infection with primary lesion at the bottom of the crypts or fossae; all that is necessary is the smallest abrasion of epithelium by which the infective agent may gain entry. An abscess may form in the submucosa and eventually burst either way, to the serosa or to the mucosa, or both; in the latter event there is a "miliary" perforation. Or the process may be infiltrative, and ulceration of the local mucosa be accompanied by spreading exudation in the muscular and serous coat all the way to the base of the appendix, with mechanical or toxic effects upon the vascular supply. We do not find, however, any adequate description of the gangrenous processes, sometimes limited to the mucosa, sometimes involving the whole walls, so eloquently described in the great American monographs and so familiar to every operating surgeon in this country. There is a good deal to be written on the geography of appendicitis. A little too much space is devoted to the description of coictrial appearances after the various types of lesion; moreover, when the author has arrived at an interpretation of the appearances, satisfactory to himself, it only leads him to the absurd conclusion that four-fifths of us suffer and survive a serious attack practically without knowing it. What he does not say, and what is to us much more surprising, is how little evidence of anything abnormal there may be in the histological picture even of an appendix that has given great trouble, and

shown to the naked eye links, twists, adhesions, and so on. Aschoff makes a point of the frequency with which the mucosa over a faecolith, though stretched, is intact or but little changed, whilst acute infiltration and ulceration is going on beyond or even proximal to it. He thinks faecoliths have little influence in initiating acute inflammation, although admitting their deleterious action in determining perforation after infection of the walls. On the whole, it must be admitted that this work has greater value as a histological exercise than as a serious contribution to practice.

KEEN'S SURGERY.

THE first article in the fourth volume of *Keen's Surgery*⁴ is from the pen of Dr. W. B. Coley, and deals with hernia. Speaking from a personal experience of over two thousand operations for rupture, he emphasizes the view generally held by surgeons, but still unappreciated by the public and by the courts, that trauma has very little indeed to do with its causation. He does not consider it justifiable to operate in infants under three or four years. It is surprising to see that he admits the propriety of employing taxis for five minutes in the treatment of strangulation. Operative measures would seem to be successful in from 80 to 90 per cent. of inguinal and femoral cases. Another article of great interest is that on the surgery of the vermiform appendix by J. B. Murphy; there is nothing very new, of course, but he makes one definite pronouncement as to diagnosis. He says that the order of occurrence of symptoms—pain, nausea or vomiting, general abdominal tenderness, elevation of temperature, and, lastly, leucocytosis—is so invariable that any departure from this sequence leads him to doubt the diagnosis. There is also a page or two on the clinical course replete with refinements of diagnosis only possible to very great experience, and withal a shade too dogmatic.

The two articles on military and naval surgery, granted the propriety of their inclusion in a textbook of general surgery, deserve no little praise. The Russo-Japanese war, that in the Philippines, and the Boer war have provided material of which good use has been made. The illustrations of wounds met with in battleships under concentrated fire are instructive, and afford good warrant for the author's maxim that the duty of the naval surgeon during an action is "not to be a hero," but to keep himself in the safest part of the ship and "wait."

The European reader who turns with some curiosity to Professor Rodman's chapter on the influence of race, age, and sex in surgical affections, will, we suspect, find it disappointing. The writer is concerned chiefly with points of distinction between the immunities and susceptibilities of the negro and the white, with scattered references to the American Indian, no doubt exactly what is wanted by the practitioners and students in the States for whom it is written. He expresses his belief that "acute ulcer only of the stomach is more common in young women than it is in men. Chronic ulcers are more common in men, and are the ones which come to operation, as they are not amenable to medical treatment."

In the various chapters dealing with the examination of the urine and with disease in the urinary organs and tract there is a good deal of overlapping, together with some conflict of opinion. For instance, the views as to cryoscopy, expressed in successive chapters by Edsall and Ransohoff, are not quite harmonious. The former discounts its value very decidedly; he also rejects Cammidge's reaction. Professor Young writes a full and instructive account of the surgery of the prostate. He cannot restrain himself from a gibe at Frey's claim to priority in the matter of suprapubic enucleation. The sections on the surgery of the ear and of the eye are fairly satisfactory from the standpoint of the student preparing for examination, but suffer from limitations of space. Each would have been so much better in a separate essay, where operative measures would not have been divorced from the other remedial indications in defects of the special sense organ. It is hardly necessary to say that the illustrations to this volume are good; we have become accustomed to expect that. The photograph on p. 147 of the

³ Die Wurmfortsatz-Entzündung: eine pathologisch-histologische und pathogenetische Studie. Von L. Aschoff, Professor of Pathology in Freiburg. Jena: Gustav Fischer. Sup. roy. 8vo, pp. 120; 12 lithographs and 22 illustrations in the text. M. 35.

⁴ Surgery, its Principles and Practice. By Various Authors. Edited by W. W. Keen, M.D., LL.D., and J. C. De Costa, M.D. Vol. iv. Philadelphia and London: W. B. Saunders Company, 1908. (Royal 8vo, pp. 1194, 582 illustrations. 30s.)

clamp operation for piles shows an unsatisfactory method of application. The part of the blade adjacent to the hinge should be compressing the largest vessel—that is, the part of the mucous membrane farthest from the anal margin. The subjects of the coloured plates are hardly worthy of such conspicuous selection. Brief but good bibliographies are appended to the various chapters.

SCOLIOSIS.

CARL NICOLADONI died untimely in 1905, but his name lives, and is likely to live for a long time, as a surgeon of an original mind whose work lay specially in the province of orthopaedics. As the originator of the procedure known as tendon transplantation for the relief of paralytic deformities his fame is secure, but he was active in many other branches of orthopaedic surgery, notably in the study of the pathology of scoliosis. To carry out his last wishes, and as a tribute to his memory, his sister has now published a small book on the anatomy and mechanism of scoliosis,* to which Professor Julius Hochenegg of Vienna contributes an introductory note. Nicoladoni's great work on this subject, which was published in the *Bibliotheca Medica* soon after his sudden death, did not fulfil his intention, which was to make the knowledge of the results of his untiring energy and research easily available for a wide circle of surgeons and practitioners. This abbreviated work thus originated, and although, owing to a chapter of accidents, six years have passed since it was written, it is still, as Professor Hochenegg says, of much value. "Time does not alter anatomical truths. They remain for ever as firm foundation stones." The fifty pages of this book are devoted almost exclusively to a description and consideration of the changes which can be demonstrated in the vertebrae of scoliotics, both the alteration in outward form and in the internal structure or architecture of the bones, but a few pages are given to the changes which may be found in the form and position of the thoracic and abdominal viscera and the ligaments and the diaphragm. Setting on one side infantile rachitic scoliosis the author declares that he has never found any evidence of rickets in the vertebrae of those cases in which the onset of the deformity occurred after the tenth year. In these cases the microscopic structure was that of healthy vertebrae of the same age. Interesting as this morbid anatomy is, the departures from the normal appear to be merely the results and not the causes of the trouble. He says in summing up that scoliosis is a deformity produced through eccentric (unequal) loading (*Belastung*) of the vertebral column, which gradually deforms the bones affected. Despite the painful and exact researches of many pathologists into the minute anatomy of scoliotic vertebrae which have led to the establishment of facts in morbid anatomy of the various changes to be found in the bones, we seem to be as far as ever from a knowledge of the determining factor, whose presence in one here and there out of many young people decides the incidence of scoliosis, although they may be all in the same environment and may all use the two sides of the body asymmetrically. The book is embellished by a fine portrait of Professor Nicoladoni and is illustrated by means of an atlas of thirty-seven plates which is conveniently stowed in a pocket of the binding, whence it is easily withdrawn for reference.

BLOOD-EXAMINATIONS IN SURGERY.

*Blood-Examinations in Surgical Diagnosis*⁸ is the title of a little book described by the author, Dr. IRA S. WILE, as "a practical study of its scope and technic." It is intended for practitioners, and deals almost exclusively with enumerations of leucocytes. Cryoscopy, blood cultures, and investigations requiring elaborate apparatus, are briefly mentioned but are obviously considered beyond the realm of practical politics with those for whom the volume is written. After giving a simple account of the easier methods of dealing with blood films and counting instruments, and describing the normal and abnormal corpuscles,

the author goes on to enumerate the various blood pictures to be expected in the commoner surgical conditions in various stages, and states succinctly the diagnostic and prognostic indications of various findings. In this section the surgical limitation is not very clear, however, unless we are to take it that the patients of surgeons are as liable to measles, influenza, pneumonia, cardiac disease, variola, and so on, as other people, and of course it is well for the surgeon to know what effect all such conditions may have on the blood findings. As no references are given, the statements read a little dogmatically, but on comparing a good many of them with a standard work we have detected no discrepancies. The book is admirably printed and bound; the coloured plate is fair, but the pen-drawings of blood corpuscles hardly fulfil their intention. The book is useful; it contains much information surgeons want in a handy form, and if the evidence here set forth of the multitudinous conditions modifying leucocytosis at a given moment rather detracts from the usefulness of blood-counts in critical diagnosis, that is not the fault of the author.

PHYSIOTHERAPY.

THE third volume of the *Bibliothèque de Thérapeutique*, published under the direction of Professors A. GILBERT and P. CARNOT,⁷ deals with physical therapeutics, and is devoted to the subjects of passive movements, massage, and gymnastics, the special articles being contributed by Professor Carnot and Drs. Dagron, Ducroquet, Nageotte-Wilbouchewitch, Cautru, and Bourcart. This system promises to be most comprehensive, for it will consist of twenty-six volumes, of which one is on the art of prescription writing, fourteen are to be devoted to therapeutic agents, two to methods of administration, and nine to the treatment of special diseases. In all probability the last series will be the most generally popular with practitioners; while such a volume as this is more likely to be appreciated by those specialists who are engaged in the direction of institutions or other places in which treatment of this kind can be carried out, although there are chapters in it which contain information of use to every one who has from time to time to recommend any of these remedial means for his patients. The early chapters deal in an interesting manner with the physiological grounds for these methods, and a good deal of evidence is brought forward to establish the doctrine that structure is modified by function, one fact alleged being that the development of the temporal muscle of mastication, which is so large in the carnivora and in the anthropoid apes, opposes the development of the temporal region of the skull, and consequently creates an opposition between the development of the brain on the one hand, and the powers of mastication on the other! The author of the article on massage insists upon the need for gentle manipulation, and condemns many of the practices of empirics and all mechanical vibrators; but while he advocates the use of massage in a great number of local diseases, he says less than one would expect of the value of "general" massage in conditions of general debility. In the section on gymnastics a full description is given of Ling's Swedish system, which is highly praised for the production of the best results in the physical training of children and recruits. A description is given of the system of Lorenz in orthopaedy. The account of the various methods as applied to special diseases includes much with which we do not agree, especially that on massage of the pelvic organs, but it is, perhaps, necessary that the advocates of such treatment should be allowed to explain it.

Mr. EUGENE PAZ is a teacher of gymnastics in Paris, who is naturally and laudably anxious that the benefits to be obtained from properly planned and regularly carried out exercises should be widely known. He has, therefore, written a book, *La Gymnastique Raisonnée*,⁹ on the subject, of which a new edition is now before us. The

⁷ *Bibliothèque de Thérapeutique*. A. Gilbert and P. Carnot. *Physiothérapie, Kinésithérapie: Massage, Mobilisation, Gymnastique*. Par Drs. P. Carnot, Dagron, Ducroquet, Nageotte-Wilbouchewitch, Cautru, Bourcart. Paris: J. B. Baillière et fils. 1909. (Post 8vo, pp. 500; 356 figures. Fr. 12.)

⁹ *La Gymnastique Raisonnée. Nécessité du mouvement rationnel. Démonstré par le mécanisme du corps humain*. Paris: Jules Roussel. 1909. (Post 8vo, pp. 255; 120 figs. 4 plates. Fr. 2.)

preface has been written by Mr. JULES SIMON, who as a former pupil of Mr. Paz testifies that when well taught gymnastic exercises do not deserve the reproach which has often been made that, as compared with games, they are dull and uninteresting. All teachers, to be successful in the highest sense, should be enthusiasts, and especially is this true of those who would teach a somewhat monotonous subject, such as gymnastics, which involves the frequent repetition of movements which in themselves are apt to seem purposeless. Such enthusiasm is more often to be found, we think, in French teachers of physical development than in English. Those who remember the late Mr. Bertrand, who for many years was a *maitre d'armes* in London will allow his superiority in "esprit" over any native teacher. Something like this enthusiasm would seem to be possessed by Mr. Paz, but in his claims for a scientific basis of gymnastics his enthusiasm rather outruns knowledge.

About half the book consists of a treatise upon anatomy, physiology, and pathology. However desirable a smattering of these subjects may be, their details have but little to do with the somewhat empirical practice of bodily exercises, and a knowledge of the origin of the red corpuscles, even if it were as certainly known as Mr. Paz seems to think that it is, has no bearing upon the question of what are the best exercises for a person afflicted with anaemia. Nevertheless the book is a useful guide to such exercises as can be done without any apparatus but dumb-bells, clubs, and bar-bells; for Mr. Paz rightly deprecates the use of very heavy dumb-bells and the performance of dangerous exercises on the trapeze, etc., although he gives directions for the use of heavy dumb-bells for those who wish to employ them.

ODONTOLOGY.

THE book on the *Evolution of Mammalian Teeth*, by Professor H. FAIRFIELD OSBORN,⁹ is a full and complete account of the homologies and evolution of mammalian teeth, according to what may be termed the American school of palaeontologists. For, although the idea of the origin of mammalian teeth from a tricuspid ancestral form had been to a certain extent foreshadowed by some Continental writers, it is to the American naturalists that the credit of establishing a theory usually known as the tributercular theory of Cope must be given, and it is based to a very great extent upon the rich Mesozoic and Eocene fauna discovered in America. The theory may be briefly but somewhat inadequately described as the assertion that, where the ancestral forms of existing mammals are known, the earliest forms present molars either distinctly tributercular—the tubercles being arranged in a triangle—or teeth the derivation of which from a simple tributercular form is obvious. In the development of the theory the attempt is made to identify those cusps of more complex teeth which are homologous with the cusps of the primitive triangle, and to trace the order and method with which additional cusps are added. A vast amount of labour has been expended on these generalizations and their results, and the theory has obtained almost universal acceptance in America, whilst it cannot be ignored even by those who do not fully accept it. Professor Osborn has been a leader in the development of the theory, and so naturally the present work is devoted to its proof. But, notwithstanding this, the book is a model of writing in the truest scientific spirit, for the views and arguments of those who reject the theory or only partially accept it are summarized and presented with the most scrupulous fairness, so that, if the reader wishes to know in brief what their views are, he could not do better than turn to Professor Osborn's pages for the information. This is a rare merit in scientific works of an argumentative kind. It would take too much space to enter into the nature of the difficulties in the way of the complete acceptance of the theory, and it must suffice to mention that they are partly palaeontological, partly zoological, and partly embryological, the order of appearance of the cusps sometimes failing to correspond to the law of recapitulation in the development of the individual of the evolution of the animal. This book will go far to widen the acceptance of the theory,

and can be cordially recommended to all who are interested in homological studies.

The development of the teeth and their relation to one another have been closely studied by means of decalcified sections, and by models constructed ingeniously from serial sections, but as the amount of calcification increases, the difficulty of avoiding disturbance of the parts in cutting sections becomes very great, hence the *Atlas of Skiagrams Illustrating the Development of the Teeth*,¹⁰ prepared by Professor JOHNSON SYMINGTON and Dr. J. C. RANKIN, representing all the calcified parts *in situ*, and with no suspicion of disturbance, fills a much-needed want in the study of the relations of the developing teeth to one another and to the jaws. The method pursued was to divide the head in the median plane and to lay each half upon a photographic plate, the back part being slightly raised in order that the shadows of the incisors might not be superposed upon one another, and to place the tube 9 in. above the specimen. The figures are the same size as the negatives, and are only, from the divergence of rays, slightly larger than life size. The heads of eighteen children, ranging from birth to 18 years, and of one adult were used, so that, as the authors claim, a complete history of the calcification of each tooth and its position at various ages in the jaws has been produced. The skiagrams are excellent, and amongst other points show very clearly the relation of the calcifying tooth to its bony crypt and the large area occupied by the enamel organ during the early stages. One interesting skiagram is taken from a rickety subject, and though no retardation has occurred in the calcification of the teeth, deficient backward elongation of the maxilla has led to the second permanent molar, and, indeed, the first also, being displaced for want of room. The single skiagram taken from an adult displays a fine set of teeth in normal position, and brings out very strikingly the smallness of the areas of lateral contact between each tooth and its neighbours.

CHEMISTRY.

STARTING with the publication of Kekulé's first paper on benzene, Dr. STEWART in his *Recent Advances in Organic Chemistry*¹¹ has endeavoured to show the main lines along which the subject has been developing during the last fifty years. In an introductory chapter he describes the struggle between the static and dynamic theories of molecular constitution, and shows how nearly Pasteur arrived at the stereo-chemical hypothesis published twenty-five years later by Le Bel and van 't Hoff. Among the other theories dealt with as being of special value in the period considered are the "steric hindrance" idea of Victor Meyer and Bischoff and the application of physics, and especially of the spectroscope. The review concludes with a note of pessimism. Compounds, Dr. Stewart laments, are turned out day by day in the laboratories, and of the hundred thousand odd bodies prepared only some 30 per cent. have been of any material value. As he suggests, the relative barrenness of organic chemistry of recent years is probably due to the fact that many of the ablest workers have concentrated their energies on physical chemistry. The most dangerous tendency of modern work is, Mr. Stewart holds, that "while we are all sufficiently glib in describing how a reaction takes place, very few of us seem to give a thought to the problem of why the reaction takes that particular course rather than another." In the body of the work the author describes the Grignard reaction, asymmetric syntheses, the polyketides, the polymethylenes, the mono-cyclic, di-cyclic, and olefinic terpenes, the synthetic alkaloids, the polypeptides, and the chemical action of light. Addition reactions and the meaning of unsaturation are carefully considered. In the concluding chapter stress is laid on the fact that those who wish to make any material advance in the subject must take into account the

⁹ An *Atlas of Skiagrams Illustrating the Development of the Teeth*. By Johnson Symington, M.D., F.R.S., and J. C. Rankin, M.D. London: Longmans, Green and Co. 1908. (Demy 4to, 12 plates and 5 drawings of dissections made to illustrate the relations of the maxillary sinus at various ages. 3s. 6d.)

¹¹ *Recent Advances in Organic Chemistry*. By A. W. Stewart, D.Sc., Lecturer on Stereo-chemistry in University College, London; Carnegie Research Fellow, formerly 1881 Exhibition Research Scholar, and Mackay Smith Scholar in the University of Glasgow. With an introduction by J. Norman Collie, Ph.D., LL.D., F.R.S., Professor of Organic Chemistry in University College, London. London: Longmans, Green and Co. 1908. (Med. 8vo, pp. 311. 7s. 6d.)

⁸ *Evolution of Mammalian Teeth*. By Professor H. Fairfield Osborn. Edited by W. K. Gregory, M.A. London and New York: The Macmillan Company, 1908. (Roy. 8vo, pp. 260; figures 215. 8s. 6d.)

arrangement of atoms in space, the mode of linkage of atoms within the molecule, the influence which the two non-adjacent atoms in a chain can exercise upon each other, the difference between ionic and non-ionic reactions, and those physical properties of organic compounds which are due to electronic motions. Dr. Stewart's book will be read with interest and profit by all who wish to have a clear conception of the principles underlying organic chemistry.

Dr. JULIUS KISS has republished his prize essay on the periodic system of the elements and the action of poisons in the form of a pamphlet.¹² It is an attempt to systematize our knowledge of poisons in the light of the periodic law. The details are of a highly technical order, and are written in the new language of ions introduced by physical chemists. The action of ions on ferment processes, on haemolysis and cytotoxicity generally, are given at length, and Loeb's work on similar lines is subjected to certain criticisms. Work of this nature is breaking new ground, and the activity of atoms and ions will no doubt in time be found to follow natural laws; it, however, at this stage hardly calls for extended criticism, and we can only congratulate the author on the progress he has made in a difficult subject.

In *Theoretische Grundlagen zum praktisch-chemischen Unterricht der Mediziner*,¹³ by A. KONSCHG, an attempt is made to provide in small compass a handbook of practical chemistry for medical students who are following a course of work in this subject in a teaching institution. In so small a volume the subject matter is necessarily presented in too condensed a form for the work to be used as a textbook. Thus qualitative, gravimetric, and volumetric analysis of inorganic substances occupy together only sixty-five small pages, while the organic section is proportionately even less extended; much knowledge of general chemistry is assumed. For its particular purpose, however, the book is calculated to be serviceable to anyone familiar with the German language. The matter given is well chosen and clearly presented.

NOTES ON BOOKS.

A CHEAP *Pictorial Guide to Gardening*, prepared by the Editor of *Garden Life* and first issued about a year ago, has reached a fourth edition.¹⁴ About half the book is given up to flowers, and there are sections on plants, including creepers, on shrubs, on bulbs, on fruits, and on vegetables. There is a final chapter containing miscellaneous information on potting, on making and maintaining lawns and paths, and various other matters. The illustrations are black and white sketches, and, being severely practical, really add to the utility of the handbook.

Dr. J. MALCOLM FARQUHARSON, surgeon to the ear and throat department at the Royal Infirmary, Edinburgh, has prepared an abridged translation of the book on diseases of the pharynx and larynx published by Dr. E. J. Moure of Bordeaux in 1904. In making the abridgement, which is entitled *Elementary Practical Treatise on Diseases of the Pharynx and Larynx*,¹⁵ Dr. Farquharson has been careful to omit no essentials, and has not commented on Dr. Moure's opinions; the book, therefore, in its English dress represents the views of a French physician who has gained a high reputation in his speciality. In reviewing the French edition (*BRITISH MEDICAL JOURNAL*, vol. 1, 1905, p. 195) we said that the whole book gave evidence of the author's great experience in practice as well as in teaching, and that it would give great satisfaction to readers, whether practitioners or students; it cannot be doubted, therefore, that Dr. Farquharson has laid the English profession under a debt of gratitude.

¹² *Das periodische system der Elemente und die Giftwirkung*. By Dr. Julius Kiss, of Buda-Pesth. Wien and Leipzig: Alfred Holder. 1909. (Roy. 8vo, pp. 190, 6 illustrations. M. 5.60.)

¹³ *Theoretische Grundlagen zum praktisch-chemischen Unterricht der Mediziner*. Von Arthur Konschegg. Wiesbaden: J. F. Bergmann. 1903. (Glasgow: F. Bauermeister. (Demy 8vo, pp. 165. 3s.)

¹⁴ *Pictorial Guide to Gardening*. By the Editor of *Garden Life* Fourth edition. London: The Cable Printing and Publishing Company, Limited. 1909. (Demy 8vo, pp. 262. 1s.)

¹⁵ *Elementary Practical Treatise on Diseases of the Pharynx and Larynx*. By Dr. E. J. Moure. Translated and adapted by J. Malcolm Farquharson, M.B., F.R.C.P. (Edin.). London: Reisman, Limited. 1909. (Med. 8vo, pp. 415; 210 illustrations. 12s. 6d.)

SECRET REMEDIES AND PROPRIETARY PREPARATIONS.

(Continued from vol. 44, 1908, page 1377.)

IN continuing his descriptions of certain secret remedies and specialities, Dr. F. ZERNIK deals with a chemical substance known under the name of *hydropyrin*. According to the makers (Chemical Factory of Geodeon Richter, of Buda-Pesth), it is sodium acetyl-salicylate. The claims made for this substance are that its neutral reaction and the absence of all irritative action render it preferable to aspirin. It is more soluble than the latter. On analysing a sample some time ago, Zernik found that a considerable amount of dissociation had taken place. The preparations yielded an odour of acetic acid, and on dissolving the solid a residue remained undissolved of free acetyl-salicylic acid. The acetic acid caused a continuous dissociation; 10 per cent. of sodium acetate was found. The manufacturers considered that this sample was taken from some of the earlier preparations, and claimed that the more recent were non-hygroscopic, and do not dissociate. Zernik, however, found that even the new preparations were highly hygroscopic and that a certain amount of dissociation took place. This fact is of importance, since if the preparation is to be used therapeutically it must be stable, and capable of being kept for a reasonable time without dissociation.

Indoform, or as it is called in America *genoform*, is advertised as the newest discovery in the treatment of gout, sciatica, rheumatism, influenza, neuralgia, headache, and toothache. The prospectus goes on to relate that indoform is a salicylic acid preparation deprived of its damaging secondary effects. Besides the curative effects of salicylic acid, it is said to possess new and extremely valuable properties of its own. The chemical composition is stated to be a combination of salicylic acid with acetic acid and formaldehyde—that is, salicylic acid-methylene acetate. The dose recommended is 0.5 gram three times a day. Frerichs, however, has found that indoform is not a single chemical compound, but a mixture of about one-third salicylic acid and two-thirds acetyl salicylic acid, with a very faint trace of a formaldehyde combination. It is possible that faint traces of salicylic acid-methyl-ester are also present. It is difficult to gain any idea as to how this substance has been prepared, but it is denied that the mode of preparation which is given in the patent leads neither to the production of the suppositions combination or to the mixture determined by analysis. Zernik points out that it is a curious circumstance that several medical articles describe the excellent action of the formaldehyde in the preparation in, for example, dissolving urates, though the quantity of formaldehyde contained is far too small to have any therapeutic action at all.

Lain is praised by the Lain Company (Berlin) as an extraordinary medicament which cures eczema, herpes, skin eruptions, wounds, ulcers of the leg, ulcerated feet, burns, ulcers, inflammation, "stretched tendons," cracked skin, and similar affections, rapidly and with certainty. Itching and pain are said to disappear almost instantaneously. It is further stated to be an excellent remedy for gout, sciatica, and neuralgia. The substance is sold at the price of M. 3.90 (about 3s. 10d.) for a box containing about 35 grams of a greyish-white ointment in which zinc oxide and naphthalin sodium soap, or a sodium soap indistinguishable from this, and the distillate of an earthy oil, were found. The price is deemed much too high.

¹ *Deut. med. Woch.*, December 31st, 1908, article xix.

THE report of the Metropolitan Hospital Saturday Fund for the year 1908, which was submitted and adopted at the annual meeting on April 3rd, showed that the receipts from workshops and business houses had amounted to £29,830, as compared with £27,140 in the previous year. A sum of £27,332, or nearly £3,000 more than in 1907, was divided amongst 209 institutions. As usual, the fund received in return for its donations letters of recommendation for patients, and issued to collectors 49,115 of these. The 22 beds endowed by the fund at four sanatoriums for consumptives proved inadequate to meet the demands made by subscribers to the fund, the deficiency being specially marked in the accommodation for women.

LITERARY NOTES.

It is announced that Messrs. Maclehose of Glasgow will shortly publish the collected works of Sir William Gairdner. The volume, which is to be edited by Dr. George A. Gibson, Dr. Eric Gairdner, and Professor Lewis Sutherland, will contain a biographical notice of the author.

Sir James Crichton-Browne discusses the question, "How much should a normal human being eat?" in a book shortly to be published by Messrs. Funk and Wagnalls Company under the title *Parsimony in Nutrition*. He maintains that the most energetic races, both physically and mentally, have been those well nourished with a meat diet. The book will appear in the latter part of the present month.

Messrs. Robman, Limited, will shortly publish a novel entitled *The Romance of a Nun*, by Alix King, author of *The Little Novice*.

Some years ago the *Practitioner* proposed to publish a series of volumes containing the original accounts of the discoveries that had marked epochs in the progress of medical science. If we remember aright, the only volume in the projected series that saw the light was Edward Jenner's *Inquiry into the Causes and Effects of the Variolæ Vaccinæ*. The idea has since become more successfully "materialized" in America in the shape of a book entitled *Epoch-making Contributions to Medicine, Surgery, and the Allied Sciences*, which is published by the W. B. Saunders Company. It consists, as stated on the title page, of "reprints of those communications which first conveyed epoch-making observations to the scientific world, together with biographical sketches of the observers." These have been collected by Dr. C. N. B. Camac, of New York. In his preface he points out that it might perhaps be thought that to-day such writings would have only a historic value, "but on reading the articles the fact becomes evident that the work and observations were so thoroughly and accurately done in the first instance that the teaching, practice, and terminology of to-day are either the same as when first communicated or based directly on these foundations." Dr. Camac adds that "one may go further and say that some of the errors of to-day are the result of disregarding or misquoting the facts clearly set forth in these original treatises." Among the contents of the volume are Lord Lister's paper on the Antiseptic Principle of the Practice of Surgery, which was read in the Surgical Section at the Annual Meeting of the British Medical Association held at Dublin in 1867, and published in the *BRITISH MEDICAL JOURNAL* of September 21st of that year; a translation of Harvey's *Exercitatio Anatomica de Motu Cordis*; John Forbes's translation of Auenbrugger's *Inventum Novum ex Percussione Thoracis Humani ut signo abstrusus interni pectoris morbos delegendi*; Forbes's translation of Laennec's *Auscultation Médiate*; Edward Jenner's *Inquiry*, above referred to, and his later works, *Further Observations on the Variolæ Vaccinæ* (1799), and *A Continuation of Facts and Observations Relative to the Variolæ Vaccinæ or Cowpox* (1800); the articles of W. T. G. Morton and J. Y. Simpson, announcing the discovery of the anaesthetic properties of ether and chloroform respectively; and Oliver Wendell Holmes's essay on the contagiousness of puerperal fever. The book, which is dedicated to Lord Lister, is adorned with portraits of the famous men whose narratives of their discoveries are reprinted, with biographical sketches and lists of their writings. We congratulate Dr. Camac on having so successfully carried out a happy idea. We hope to deal more fully with the book in a further notice.

The Annual Report of the Library Committee of the College of Physicians of Philadelphia for 1908 states that the number of volumes in the Library is 77,603. The number of unbound *Reports and Transactions* is 9,115, of unbound theses and dissertations 22,681, and of unbound pamphlets 67,122. In addition to these there are 2,854 duplicates. The Library receives by purchase, exchange, and gift, 630 periodical publications—183 American and 447 foreign. Through the liberality and efforts of Dr. W. W. Keen there were added to the Library during the year to which the report relates thirty-three rare and valuable medical works, of which twenty-one were printed in the fifteenth century, and come under the head of *incunabula*. Among them are the following:—Arnoldus

de Villa Nova: *De arte cognoscendi venena*, n.p., ca. 1473, 4to; Petrus Egidius (Carbolensis): *Incipit liber magistri Egidii de pulsibus metrice compositus*, Paduae, 1484, sm. 4to; Mathaeolus (Perusinus): *Tractatus clarissimi philosophi et medici Matheoli Perusini de memoria*, Rome, ca. 1464, sm. 4to; Gualterus Birlaeus (Walter Burely): *Preclarissimi viri Gualteri Bureli anglie sacre pagine professoris excellentissimi super artem veterem Porphyrii et Aristotelis expositio*, Venetiis, 1497, fo.; Avenzoar (Abumonar): *Incipit liber theoricis dialismoda caliditadibz*, Venice, 1497, fo.; Hieronymus Brunschwig: *Liber de arte distillandi*, Strasburg, 1500, 4to; Petrus Tartaretus: *Totius philosophiae necnon metaphysicae Aristotelis*, vol. ii., Lyons, 1500, 4to. Doubtless this is a learned and valuable work, but the name of Tartaretus is probably known at the present day only to readers of Rabelais, who assigns to him a treatise, *De modo cacandi*, which figures among the books found by Pantagruel in the Library of St. Victor in Paris. There are two other works in the Library of the Philadelphia College of Physicians which, while not *incunabula*, are worthy of special mention, such as Avicenna (*Lébr V. Canonis medicinae*), Arabic text, Rome, 1593—this is described as an extremely handsome copy printed in Arabic on tinted paper, with the original parchment binding, stamped with the seal and crest of the Duke of Alenteuz; and Dioscorides: *Codex Aniciae Julianae*, described as a magnificent edition of the photograph facsimile of the Dioscorides codex, in two large folio volumes, published at Leipzig in 1906.

Our American contemporary *Science* of March 19th contains an interesting note by Mr. C. A. Browne on adulteration and the condition of analytical chemistry in old Rome. Most people, perhaps, would be inclined to deal with the subject as summarily as is done by Horrebow in his chapter concerning Snakes in Iceland, which Johnson boasted he could repeat by heart. It was not a difficult feat, as the whole chapter is as follows:

There are no snakes to be met with throughout the whole island.

Mr. Browne, however, says that, as a matter of fact, enough reliable practical chemical knowledge has come down to us in the writings of Pliny, Dioscorides, and others to form a very respectable treatise. The *Natural History* of Pliny, for example, is interwoven throughout with little digressions upon what is now termed the "chemistry of everyday life." For instance, one finds references to the use and efficiency of burning sulphur for fumigating and purifying the interior of dwellings, and to the lowering of a burning light into wine vats to determine whether or not it is safe for workmen to descend in order to remove the lees. Much of the matter which Pliny has gleaned in his *Natural History* was common knowledge centuries before his time. The use of burning sulphur as a disinfectant, for example, is mentioned by Homer in the *Odyssey*. Odysseus, after the murder of the suitors, cries out to his aged nurse:

Bring sulphur, old woman, the cleanser of pollution and baneful fire, that I may sulphur the chamber.

The application of specific gravity to the testing of various bodies, liquid as well as solid, seems to have been common after the time of Archimedes. Pliny alludes to the use of some form of specific gravity balance by which the purity of water could be tested. The adulteration of foods and other commodities of life was as common in the early days of the Roman Empire as it is to-day. Pliny repeatedly calls attention to the many frauds of his time. "It is the natural propensity of man to falsify and corrupt everything," he exclaims while writing of the adulteration of honey, and he complains of the use of gypsum, pitch, lime, rosin, wood ashes, salt, sulphur, artificial pigments, etc., for the sophistication of wines. He denounces the whole fraternity of Roman apothecaries with special bitterness. Many pages of the *Naturalis Historia* are, in fact, devoted to the disclosure of the dark secrets of the shops of the ancient druggists (*tenebrae officinarum*). In the long list of tests which Pliny enumerates for detecting the various forms of adulteration practised in his time, by far the greater number relate to the use of our simplest sense perceptions, such as taste, smell, colour, feel, brittleness, etc. The ancients, guided by such perceptions, were unquestionably better judges of the purity of many articles of food than we are to-day. Pliny, in fact, says Mr. Browne

makes such a fine classification of tastes and flavours, that the translator finds himself at a loss for suitable terms in which to express the meaning. Whether this indicates an over-refinement of the test perception among the Romans through the influence of a long line of epicures dating from Lucullus, or simply an atrophy of our present powers in this respect, it would be difficult to say. Professional tasters were in demand during the early days of the Roman Empire to determine the quality of wines; and, notwithstanding our advanced chemical knowledge of the score or more esters which give wines their characteristic bouquet, the final criterion in the judgement of a wine, now as in the days of Pliny, is the evidence of a skilful taster. But the ancients had many other means of testing the purity of their commodities of life than those of simple taste and smell. A good illustration of such tests is given under Pliny's description of balsams, which we give in Philemon Holland's translation rather than in the brief paraphrase quoted by Mr. Browne. The passage occurs in Book 12, ch. 25:

This is also called Xylobalsamum, and it goes into odoriferous compositions: for in default of the right Baulme liquor, the Apothecaries make a shift to serve their turn with the wood alone, called Xylobalsamum. As for the very bark, it enters also into many medicinale confections: no marvell therefore if it carries some price. But it is the liquor only that is so precious, the liquor it is which yields that most fragrant smell; then follows the grain or fruit in a second degree, the bark in a third, and the wood as it is last, so it hath least grace and credit. Of the wood, the best is that which in color resembles Box, and gives sweetest smell. But of the fruit, the greatest graines and the weightiest, be most esteemed: such bite at the tongue's end, and be hote in the mouth. Howbeit, this is adulterated with the seed of Hypericum, that comes from the cite Petra. But the deceit is soone detected and found, for that seed is not so big, so massie and full, nor so long as the true graine of Baulme: besides, it hath but a dull sauer or none at all, and in tast resembles pepper. The liquor is knowne to be right or good, if it be oleous and fat, thin, and sheere, somewhat inclining to red, and, if in rubbing between your fingers, it renders a pleasant sauer. The white Baulme may be raunged in a second place of goodnesse: the greene and thicke is not so good as it: but the blacke is worst. For Baulme as well as Oile, will be stale and worse for the age, if it be kept too long. This is moreover observed, that in every incision, that which flowed forth before the seed is ripe, is most precious. Ouer and besides, this Baulme may be sophisticated with the owne seed: and hardly can this counsaige be found out, but that it hath a bitterer tast than that which is natural. For the good Baulme should be pleasant and delicate in the mouth, not soure or tart at all: only in smell it should haue a harsh verdeur. Corrupted it may be otherwise with Oile of Roses, of Cyperus, of Lentisque, of Masticke, of Ben, of Terebinth, and Myrtles, also with Rosin, Galbanum, and Cyrian waxe, as occasion serues, and according as men list to sophisticate it. But the greatest knauiery of al, is to mingle gum among it: for being so handled, it will sticke cleane to the palme or inside of a mans hand, nay, it will sinke in water to the botome, which are two chiefe properties of the right Baulme. For the very true and perfect Baulme ought to cleane too: but when it hath gum mingled among, stick it will likewise: but it will gather soon a brittle rouse or crust upon it, which quickly cracks and breaks. Also this sophistication is found out by the tast. But in case there be any trumperie of Wax or Rosin, the fire will soone bewray it: for when it burnes, it will yeeld a more muddie and blacke flame. As for the sophistication made with honie, it may soone be knowne: for presently the fire will take it, and gather thicke about it. Ouer and besides, put a drop of pure Baulme into warme water: it will settle to the botom of the vessell, and congeale; but contrariwise, the counterfeite Baulme, will flote and swim above like oile. Again, if it haue Galbanum in it, yee shall see a white streak or circle round about it. To conclude, would you know in a word the right Baulme indeed? It will turne milke, and cruddle it, and it will not stain a cloth. In summe, there is no melchandise and commodity in the world, wherein there is practised more fraud and deceit, than in the traffike of Baulme. For a Sextare or wine quart of Baulme will cost a thousand Roman deniers by retails, which was bought for three hundred and no more at the hands of the factors vnder the Emperour, who sold it first. Whereby a man may see how gainful it is to increase this liquor by sophistications. As for the Baulme wood Xylobalsamum, the price of it is six deniers a pound.

The flame test is mentioned repeatedly by Pliny in connexion with the testing of drugs and chemicals. In some cases the colour and smell of the smoke were observed, in others the colour of the flame, or the property of decrepitating. The examples cited, however, show that the fragmentary records of ancient science preserved by Pliny, full as they are of inaccuracies and absurdities, contain a large amount of reliable chemical knowledge. As Mr. Browne says, if the 474 authors whom Pliny consulted in the preparation of his *History* had come down to

us intact we may be sure that our knowledge not only of historical, but also of practical, chemistry would be greatly enriched.

British Medical Association.

GRANTS AND SCHOLARSHIPS FOR SCIENTIFIC RESEARCH.

GRANTS.

THE Council of the British Medical Association is prepared to receive applications from members of the Medical Profession for Grants in aid of Researches for the Advancement of Medicine and the Allied Sciences.

The Grants are made subject to the following conditions:

1. That the work of the Grantee shall be subject to inspection by the Science Committee of the Association.
2. That each Grantee shall furnish to the Science Committee, on or before May 15th following the allotment of the grant, a report (or, if the object of the grant be not then attained, an interim report, to be renewed not later than the same date in each subsequent year until the final report is presented) containing:
 - (a) A statement, in a form satisfactory to the Science Committee, of the results arrived at, or the stage which the inquiry has reached;
 - (b) A statement of expenditure incurred, accompanied by vouchers as far as possible;
 - (c) A reference to any Transactions, Journals, or other publications in which the results of the research have been announced.

SCHOLARSHIPS.

The Council of the British Medical Association is also prepared to receive applications for Research Scholarships, as follows:

1. AN ERNEST HART MEMORIAL SCHOLARSHIP, of the value of £200 per annum, for the study of some subject in the department of State Medicine.
2. THREE RESEARCH SCHOLARSHIPS, each of the value of £150 per annum, for research in Anatomy, Physiology, Pathology, Bacteriology, State Medicine, Clinical Medicine, or Clinical Surgery.

Each Scholarship is tenable for one year, but is renewable by the Council, provided that the whole period of tenure shall not exceed three years.

The Scholarships are awarded subject to the following conditions:

1. That the work of the Scholar shall be subject to inspection by the Science Committee of the Association.
2. That he shall furnish the Science Committee, on or before May 15th following the grant of the Scholarship, with a statement of the work done by him.
3. That he sign an undertaking to abide by the above and other regulations affecting Scholarships, a copy of which will be supplied to him.

Applications.

Applications for Grants and Scholarships for the year 1909-10 must be made, not later than May 27th, 1909, in the prescribed form, a copy of which will be supplied on application to the Medical Secretary, 429, Strand, London, W.C.

Each application should be accompanied by a recommendation from the head of the laboratory in which the applicant proposes to work, setting out the fitness of the candidate to conduct such work and the probable value of the work to be undertaken. This is not intended, however, to prevent applications for Grants in aid of work which need not be performed in a recognized laboratory.

J. SMITH WHITAKER, *Medical Secretary.*

429, Strand, W.C.,
March, 1909.

Nova et Vetera.

A SEVENTEENTH CENTURY SPIRITUAL HEALER.

THE well-meaning persons who are now striving to gain a footing for "spiritual healing" among the recognized methods of treating disease are not only imperfectly equipped on the scientific side for the task they have undertaken, but seem to think they have made a new discovery. Yet, as has repeatedly been pointed out in this JOURNAL, the influence of the mind over the body is a commonplace of clinical experience, and has been used in one form or another since the beginning of recorded history. Eminent modern practitioners have employed it in suitable cases with success; among them we need only name Benjamin Brodie and Charcot. The former made hysterical women walk who had been bedridden for years, and whose limbs had wasted owing to want of use. Charcot sent many patients to Lourdes. Mrs. Eddy did not discover, still less create, a new force; she only had the shrewdness to discern how one that had been inherent in man since he developed into an *animal rationale* might be put to profitable use on a large scale. What she does had been done throughout the ages, and is still done by priests of various religions—Christian, Mohammedan, and Hindu—in temples and churches of the most diverse cults, at shrines and tombs of holy persons of every religion, and by living men and women who have the power of exciting the faith that "moves mountains." The present revival of faith healing presents absolutely no feature of novelty, unless it be the misty metaphysics and pseudo-scientific phraseology which form the cloud from which comes the voice of the oracle.

The "laying on of hands" is a very old therapeutic method, if we may call it so, of which the royal touch for the King's Evil practised for so many centuries is only one example. The ritual of this practice was described in detail in the BRITISH MEDICAL JOURNAL of May 13th, 1899.

But it was not only the Lord's Anointed who claimed the power of healing. One need not sweep aside as fables the miracles said to have been wrought by the saints of the Roman Calendar. A certain number is required to establish a person's claim to canonization and these are subjected by the *advocatus diaboli* to searching criticism. It is probable that many of them are true, but, without expressing any theological opinion on the question of miracles, we think it may be assumed with confidence that such cases are all instances of the operation of the mind on the body. Miracles of healing are not confined to saints whose names are written in the Roman Calendar; some sturdy Protestants have claimed the power of healing. Of these one of the most notable is Valentine Greatrakes who flourished—for a time—in the seventeenth century, and finally lapsed into obscurity. The little that is known of his life, and of the fruits of his gift of spiritual healing, comes to us mainly on his own authority.

He was the son of William Greatrakes of Affane in Waterford, and was born on February 14th (whence his Christian name) in 1628. His mother was the daughter of Sir Edward Harris, Knight Justice of the King's Bench in Ireland. He was educated at the Free School of Lismore till the age of 13, and it was intended that he should pursue his studies at Trinity College, Dublin, when the outbreak of the rebellion in 1641 led his mother, who had by that time lost her husband, to take refuge in England with an uncle whom he describes as "a saint in his life and conversation." He was for some years under the tuition of John Daniel Getsins, High-German Minister at Stock Gabriel in Devon, where he spent some years "in studying Humanity and Divinity." Returning to Ireland in 1647 he spent a couple of years at the castle of Cappoquin, where he meditated on the vanities and wickedness of the world. He then volunteered for service in Cromwell's army, and held a commission as lieutenant in the regiment commanded by the Earl of Orrery in Munster. When the army was disbanded in 1656 he was appointed a county magistrate, registrar for transportations, and a justice of the peace for County Cork. At the Restoration he was deprived of his appointments, and gave himself up to a life of contemplation. He lived at Affane,

where he says he got by his industry a livelihood out of the bowels of the earth, and employed himself in helping the poor.

It was in 1662 that the consciousness came to him that he possessed the gift of healing. His wife laughed at him, but Greatrakes took himself very seriously indeed. The following is the account of the matter given by himself in a letter to the Honourable Robert Boyle, described as "the Father of Modern Chemistry and Brother of the Earl of Cork":

About four years since, I had an impulse, or a strange persuasion in my own mind (of which I am not able to give any rational account to another) which did very frequently suggest to me that there was bestowed on me the gift of curing the Kings-evil; which, for the extraordinariness of it, I thought fit to conceal for some time, but at length I communicated this to my wife, and told her, that I did verily believe, that God had given me the blessing of curing the Kings-evil; for whether I were in private or in public, sleeping or waking, still I had the same impulse; but her reply was to me that she conceived this was a strange imagination; but to prove the contrary, a few days after there was one William Maber of Salterbridge in the Parish of Lismore (a Tenant of your brother's the Right Honourable the Earl of Burlington and Cork) that brought his son William Maber to my house, desiring my Wife to cure him, who was a Person ready to afford her Charity to her neighbours, according to her small skill in chirurgery; on which my wife told me there was one that had the Kings-evil very grievously in the eyes, cheek, and throat, whereupon I told her that she should now see whether this were a bare fancy or imagination as she thought it, or the Dictate of Gods Spirit on my heart; and thereupon I laid my hands on the places affected, and prayed to God for Jesus sake to heal him, and then I bid the Parent two or three days after to bring the child to me again, which accordingly he did, and then I saw the eye was almost quite whole, and the node, which was almost as large as a pullet's egg, was suppured, and the throat strangely amended; and to be brief to God's glory I speak it within a month discharged itself quite and was perfectly healed, and so continues, God be praised. Then there came one Margaret Macshane of Ballinechy of the Parish of Lismore, and a Tenant of your brother's the Earl of Cork, who had the Evil 7 years and upwards, which had spread itself from the bottom of her stomach upwards, all over to her throat, neck, and nose, and so all over her back shoulders and armpits, so that I could not see one place free from the Evil, where you might put a sixpence, and to speak the truth she looked so dreadfully and stunk so exceedingly, that she would have affrighted and poisoned any one almost that saw or came near her; whereupon I spoke to one Doctor Anthony (a famous physician then at my house) desiring him to take commiseration on her for Gods sake; His reply was that she was men out with the evil, and that she had a great deal of Ireland could do good; whereupon I said, I did believe that there was one that could do her good and cure her; the Doctor demanded who that man was; my answer was, that through Gods blessing I could; but he slighted the matter saying, if he saw the person cured, he would not question but I might heal all diseases; but I replied I was not of his opinion as to the latter part, but said, he should be convinced of the former; which accordingly I tell out (God be praised) for my hand augmented the nodes, and drew up and healed the sores, which formerly I could not have endured the sight of, nor smell, nor touched them without vomiting; so great an aversion had I naturally to all wounds and sores; so that the poor woman about six weeks afterwards came perfectly well to my house (and so continues) where Doctor Anthony was then also, to see my wife, and gave God praise and me thanks; who carried her to Doctor Anthony, and told him that he praised her for my hand, and could and did great things by poor and worthless instruments, and therefore he should not limit him for the future. After this many people infected with the evil came to me from several counties and I stroked them, and desired God out of his abundant mercy to heal them also who (blessed be His Name) heard my prayer and delivered them; so that few or none, unless those whose bones were infected and eaten, returned without their cure.

There is always a limitation to the faith healer's power, and it is not surprising to find that Greatrakes failed in the very cases which might have been described as "the mere despair of surgery." He did not long confine himself to "stroking" for the King's Evil. When "the Ague was very Epidemical whole Families being struck down with it," he found an impulse stirring within him to cure that disease also. He says:

This also I told my Wife, who could not be persuaded to it; and the next day there came to my house a neighbour's wife, who lived nigh Tallowbridge (a place well known to you) by name Bateman, the Naylor's wife that is there, who had a most violent ague, on whom I laid my hands and desired God Almighty to cure her, who in Mercy heard my prayer, and so the ague ran through her, and she went away perfectly cured; her ague, upon which her husband and children were afflicted with the same disease, applied themselves to me, on whom I laid my hands in like manner with the same success,

and so many more came to me afterwards, and were cured by Gods great and wonderful power in the like nature.

It was not long before the impulse came to him to display his gift in a larger sphere. He says:

This impulse I had the Sunday after Easter-day, the 2nd of April .65. early in the morning, the Wednesday ensuing I went to Cornet Deans (about some Occasions I had with him) to Lismore, where there came into his house to me a poor man, that with a violent pain in his loins and flank went almost double, and had also a most grievous Leg very black, wherein were five ulcers; who desired me for Gods sake that I would lay my hands on him and do him what good I could. (But by the way take notice, That as God gave me the several gifts from time to time, he always sent patients that applied themselves to me, for I never sought after any from the first moment to this very instant.) Whereupon I put my hand on his loins and flank and immediately run the pains from him, so that he was pleased, and could stand upright without the least trouble. Then I put my hand on his ulcerous Leg (which the chirurgeons after they had shewed all their skill on him told him it was perished at the bone, and so must be cut off, but that he wanted £3 to give one of them for his pains, as he informed me) which forthwith changed colour and became red, and 3 of the ulcers closed up, and the rest within a few hours afterwards: so that he went out well, that could hardly by the help of his staff crawl in, and within two days afterwards he fell to his Labour (being a Mason by Trade) and so continued several months afterwards to my knowledge, and to this instant (for ought I know).

Then Greatrakes went to see Colonel Phaire at Cahirmoney, in the county of Cork, who told him he was vexed with an ague. He proceeds:

My Reply was, that through Gods blessing I could cure him: He told me that I was welcome, and within an hour it would seize him, who thought it impossible for him to live two fits more, for after the cold fit his hot one continued for fourteen hours in that extremity, that no fever could be more violent: accordingly as he had said his cold fit arrested him, and then I bid him to give me his hand which he did, and it pleased God that from that time his Fit left him so that he had it no more: Then there came several People to his house troubled with several Diseases, desiring me for Gods sake to cure them (at which passage I was much amazed, not having told him nor anyone, but my Wife and brother, of the Impulse I had, which was but the Sunday before) some had the Ague, several others the Falling-sickness, others the King's-evil, one the Fever, some pains, some Aches and lameness, on whom I put my hands, little thinking that the pains would skip and fly from place to place till they did run out, but that the persons might be cured without any such notion by the laying on of my hands; and several, nay most of all Diseases were immediately cured, and those that came exceedingly lame, and so had continued for many years (by their own reports and others) went well home rejoicing and praising God.

To the reality of the cure of Phaire's ague there is said to be independent testimony in unpublished letters from the old regicide's son. We should like better assurance, especially as to the diagnosis. A more significant case is that of Flamsted, the famous astronomer, who in 1665, when a young man suffering from chronic rheumatism and other ailments, was "stroked" by Greatrakes with little or no benefit. Nevertheless, the fame of the "healer" still grew; and so many were the patients who resorted to him on the three days in the week which he set apart for healing that the Bishop and Dean of Lismore reposed him for practising medicine without a licence from his Ordinary. It need scarcely be said that Greatrakes considered himself above such carnal restrictions. At the suggestion of Henry More, the Platonist, Greatrakes was invited to England to treat Lady Conway for headaches. In her case, too, he failed; but many other persons in the neighbourhood of her Warwickshire home are said to have been healed. He was invited to Worcester, and then, by direction of the Secretary of State, Lord Arlington, to London, where he lived for some months in Lincoln's Inn Fields, exercising his "gift" with varying success. He failed in an exhibition given at Whitehall before the King and his courtiers. It may be conjectured that this was the beginning of the end.

Naturally Greatrakes's proceedings excited much interest. Henry Stubbe, a physician of Stratford-on-Avon, described him as the "Miraculous Conformist," and explained his "gift" by the following remarkable hypothesis:

That Mr. Greatrakes was possessed of some peculiar temperament, as his body was composed of some particular ferments, the effluvia whereof being introduced, sometimes by a light, sometimes by a violent friction, restore the temperament of the debilitated parts, regenerate the blood, and dissipate the

heterogeneous ferments out of the bodies of the diseases, by the eyes, nose, mouth, hands, and feet.

Stubbe's pamphlet brought a hostile critic, David Lloyd, into the field with a reply entitled *Wonders no Miracles*. To this Greatrakes retorted with the autobiographical letter from which we have already quoted. In that letter fifty-three testimonials are cited, among those testifying being Boyle himself, Andrew Marvell, Roger Cudworth, the philosopher, John Wilkins, afterwards Bishop of Chester, and other persons of note whose honesty could not be impugned, however much we may be disposed, in Touchstone's phrase, to disable their judgement. In the letter, which is dated 1666, Greatrakes says to Boyle that he has

Assumed the confidence to make this address to your Honour, whose Repute and Testimony to the World will be so powerful (knowing your Wisdom, Devotion, and Learning to be so great) that Truth may find Relief, God have glory and his poor instrument be justified before men, who hath no farther design in the distribution of that Talent which the All-healing God has entrusted him withal, then the honour of his Maker, and the good of his poor Fellow creatures, whose Distempers (many of them) neither Art nor Physick probably could reach; which caused him cheerfully (that he might not be found an unfaithful steward to all his worldly treasures and delights behind his back, to make his house an Hospital, and forsake his own interests and advantages; to labour day and night—and oftentimes run the hazard of his liberty and life by the crowds, pressings, steams and stinks of the multitudes and ulcerous persons (which you can well witness few men can brook or undergo) and what is worse than all this, the scandalous and false reports of lying tongues.

Of the way in which Greatrakes refutes these scandalous and false reports, the following may serve as a specimen:

Then he [Lloyd] charges me in page ibid with being a good fellow (according to his sense) and having converse with women notoriously scandalous; and also with many fallacies out upon poor people as to the place of my abode; and several other things as true as these. To which my answer is, that there is no person that knows me but will acquit me of being excessive either in eating or drinking; neither was I ever charged or suspected (till by this gentleman) who puts his name to nothing, nor seems to care what he says of man, woman or child, to be incontinent with women or to have to do with any (but my wife) in all my Life time.

He denies, further, taking, or allowing his servants to take, money from patients.

Dealing with objections which he says he had often heard from many, to wit, What need had God to cure diseases in this age of the world by any extraordinary means? Wherefore God did make choice of him for the purpose? and many such questions. Greatrakes says,

My reply was a smile, which was the best I could use in answering such fond enquiries.

It certainly was a diplomatic answer. Nevertheless, he proceeds to give two or three reasons:

The first is to convince this Age of Atheism,—who cannot yet believe Jesus to be God, when they see pains and diseases to vanish, and evil spirits fly his Power; as I have good cause to believe the Falling-sickness and other Distempers I have met withal sometimes to be. Next, God may, to abate the pride of the Papists that make Miracles the undeniable Manifesto of the truth of their Church make use of a Protestant to do such strange things in the face of the sun, which they pretend to do in cells.

To the argument, based on his failure in some cases, that "if this work were of God all would be cured," he answers:

That God may please to make use of such means by me as shall operate accordingly to the disposition of the Patient; and therefore cannot be expected to be like effectual in all. They also demand further, why some are cured at once coming and not all; and why the pains should flye immediately out of some, and take such ambuges in others; and why it should go out of some at their eyes, some at their fingers, some at their toes, some at their noses, others at their ears or mouths? To which I say: If all these things could have a plain and rational account given of them, then would there be no reason to account them strange.

His method is illustrated in the following curious passage:

Some will know of me why, or how, I do pursue some pains from place to place, and till I have chased them out of the Body by laying my hands on the outside of the clothes only (as is

usual) and not all pains. To which I answer: That I and others have by frequent experience been abundantly satisfied that it is so, though I am not able to give a reason why it should be so although I am apt to believe there are some pains which afflict men after the manner of evil-spirits, which kind of pain cannot endure my hand, nay not my glove, but fly immediately, though 6 or 8 coats and cloaks be put between the patient's body and my hand as at York house, the Lady Ramsloughs, and divers other places since I came to London (where many wise and learned men have been present, as well as frequently in Ireland), has been manifested.

Of course the Devil bulks large in Greatrakes's pathology, but in this he was not different from most people of his time. But the "stroker" was more than a match for the Evil One:—

I have met with several Instances which seemed to me to be Possessions of dumb Devils, deaf Devils, and talking Devils; and that to my apprehension, and others present, several evil spirits one after the other have pursued out of a woman, and every one of them have been like to choke her (when it came up to her Throat) before it went forth; and when the last was gone she was perfectly well, and so continued. There have been others that have fallen down immediately as soon as they have seen me, which the Mayor of Worcester, Colonel Birch, Mayor Wilde, and many hundreds both at Worcester, and here and other places, were eye witnesses of. Many when they have but heard my voice, and have been tormented in so strange a manner that no one that has been present could conceive it less than a Possession; as I will instance in one at York house (where Sir John Hinton, Colonel Talbot and many others were present) who had somewhat within her which would swell her body to that excessive degree on a sudden as if it would burst her; and then as soon as I put my hand on that part of her Body where it did rise up, it would fly to her Throat (or some other place) and then it would cause her neck to swell half so big again, and then almost choke her, then blind her, and make her dumb and foam, and sometimes fly into her hand, and so contract and fasten it, that neither Sir J. Hinton or any else that did try (as there were many could with all their strength open one finger of her hand; nor would it let fly his hand in the least nor any other person there, till I put my hand on it, or my glove; nay I often times brought it up into her Tongue (by running my hand on her Body, on the outside of her Cloathes, up to her Throat) which has swoln in an instant nigh as big again, and has been seen plainly to play from place to place, and at length with great violence of belching (which did almost choke her, and force her eyes to start out of her head) it went forth, and so the Woman went away well. Whether this were a natural Distemper, let anyone judge that is either a Divine, a Philosopher, or Physician.

He next proceeds to explain the *modus operandi* of his gift:—

Now, Sir, another Question hereon will arise (which I have often times heard from others) before I proceed; and that is, whether this operation of mine proceeds from the Temperature of my Body, or from a Divine Gift, or from both? Do which I say that I have reason to believe that there is something in it of an extraordinary gift of God; the Reasons and Arguments which incline me to this belief are, That I am very sensible of the particular time when this gift was first bestowed on me, before which time I had it not; because having my self for several years together been most violently troubled with the head-ach, though I have put my hand a thousand times to my head and held it, it would neither remove nor run out the pains but since God gave my hand this Gift, I have no sooner put it on my head where it was troubled but I have removed it and run it out. I have also oftentimes held my Friends heads formerly, when they have been in violent pains with the head-ach; but I never could hear them say their pain removed or ceased, which now immediately it do's in very many. . . I shall suggest to you an Experiment made at the House of that excellent Person your Sister the Lady Ramsloughs, where I tried (to satisfy the curiosity of some there) with a Napkin which I rubbed my breast withal, and with my shirt which I had pulled off, being very hot, whether that would remove the pains of a Woman which was in strange fits there (as my glove, being tried, did oftentimes) and it would not.

He admits his failure to cure Lady Conway, but appeals to Boyle as an eye-witness of the "remarkable cures" he had wrought in London. He says nothing about his failure at Whitehall.

We quote two of the testimonials which he adds as samples of the rest:—

Sir John Godolphin's Testimony. Anne Robinson, Servant to Major Wilmott next door to the Hand and Pen in Aldersgate Street, troubled with a Pthysick for the space of six years, was stroked 21 April, 1666, and the pain removed out of her stomach into her left side; thence at a second stroking it removed into her thighs and legs; and lastly into her right foot and toes, whereinto (her eyes being covered) a pin was thrust divers times, without her feeling or being sensible of it, till her foot and toes were stroked; but then she immediately stood at the first touch of the pin, and she declared her pains were gone, as

well out of her feet and toes, as out of all other parts. In the presence of J. Godolphin Knight; Alb. O. Faber, Med.; George Weldon; J. Fairclough, M.D.; Ed. Sleight; John de Bray. Note.—That no blood issued upon the pricking of this woman's toes, nor of divers others who have been pricked in the like case, before me, J. Fairclough, M.D.

Dorothy Pocock's Certificate. Dorothy, the wife of John Pocock of Chiveley in the County of Berks, aged 45, had a Tumour began in her breast about August 1666, which in the beginning of April 1666 was grown so big as a large Pullets Egge, and conceived by Sundry Physicians and Chirurgeons to be a Cancer, and no other way of curing it then by cutting out; was stroked Twice by Mr. Greatrak's and after the second time, the Tumour was grown softer, so that he opened it, and out thereof flowed a great quantity of concocted matter; and after that by gentle stroking Mr. Greatrak's brought forth the bag wherein the matter had lyen out of the small orifice; and she professes herself to be very well of her breast, and also to be freed of a great pain which she had had in her arm and shoulder for the space of 3 months last past. April 10. 1666. Dorothy Pocock. In the presence of Andr. Marvel; J. Fairclough; Tho. Alured; Tho. Pooley.

In 1666 Greatrakes returned to Ireland and led the life of a country gentleman, only occasionally practising his cure. He died in 1683. His meteoric course as a "stroker" recalls the proverb about the rocket and its stick. In this he resembled most "healers." There is a curious similarity in his method to that of some of those who at present are practising spiritual healing. The laying on of hands, and the feeling that virtue went out of him in the act, exactly corresponds with what we have heard described by faith healers as happening to themselves. In the absence of anything like scientific evidence any discussion of his "cures" is needless. Even assuming the truth of all his statements, there is nothing more in what he did than in the "miracles" of faith-healing which occurred in the early part of the eighteenth century at the grave of the Jansenist Deacon François de Paris, in the cemetery of St. Mard, Paris, which so excited the jealousy of the Jesuits that they procured an order that they should be stopped by the police. This order is enshrined in the famous epigram:

De par le Roi, défense à Dieu
De faire miracle en ce lieu.

THE POST OFFICE SANATORIUM FOR CONSUMPTION.

THE second conference of the Post Office Sanatorium Society held on March 27th in Manchester was attended by sixty persons, of whom forty-three were delegates. The Secretary reported that the total membership of the society was over 37,000, of whom 7,500 had joined during the last two years; about 42 per cent. of the members belonged to London, 51 per cent. to England and Wales, and the rest to Scotland and Ireland. The number of cases dealt with was 153, but of these 26 were still under treatment, while 39 had been either found unsuitable for treatment or had withdrawn, and 3 had died before seeing the referee. The treatment had been completed in 85 cases, and the disease had been arrested in 43 per cent.; improvement, sometimes almost amounting to arrest of disease, had occurred in 40 per cent.; no improvement was observed in 15 per cent., while 1 case had died. Thus about 83 per cent. had received great benefit from the treatment. Five female members had been treated, but as there was no accommodation for females at the sanatorium at Benenden, they had been treated at the expense of the society at other establishments. Taking all the cases together, the average length of treatment had been about twenty weeks, though 1 case had received sixty-six weeks' treatment.

The income from subscriptions in 1907 had been £3,227 and the amount paid for maintenance was £1,185. In 1908 the income had increased to £3,334, but the sum paid for maintenance had increased to £2,434, more than double the amount for the previous year. The balance standing to the credit of the society at the end of 1908 was £1,982, which the Treasurer considered was very satisfactory for so young a society. Mr. C. H. Garland, the Secretary, drew attention to the great leakage in membership from deaths, retirements, resignations, and other causes. In the past two years this leakage had amounted to 750 members each half year, which showed the necessity

spending pretty freely on organization work. He also drew special attention to the necessity of getting patients in the very first stages of the disease. With the help of the medical superintendent of Benenden he had been able to classify 80 cases which had received complete treatment, according to the stage of their disease or admission. The patients were divided into three classes: Class I, early stage, only one lobe of the lung affected, 33 cases; Class II, moderately advanced, two lobes affected, 25 cases; and Class III, advanced, three or more lobes affected, 22 cases.

Table showing in Percentages the Results of Treatment in Each Class.

Class.	Arrested.	Improved.	Unimproved.	Died.
I	78½	18½	3½	0
II	48	32	20	0
III	4½	54½	36	4½

Thus the arrested cases are far greater in number in the earlier stage, while failures are immensely increased in the advanced stage. The society had made a strong endeavour to get all cases in an earlier stage by publishing descriptions of the early symptoms. The result had been most gratifying, and had fully justified any expense incurred. An attempt had also been made to prevent the unjust ostracism of consumptives. They had found that there was an exaggerated idea of the infectiousness of the disease, and that consumptives were often treated almost as lepers. They wished it to be known that the infectiousness of consumption was quite different from that of fevers. In the first place, in the early stage it was not infectious at all. Dr. Bulstrode had pointed out in a recent report to the Local Government Board that from the records of consumption hospitals it was difficult to believe that phthisis is in any degree personally communicable. At any rate, it requires prolonged exposure and lowering of the resistance before it is communicated. Recently one patient whose disease had been arrested and practically cured returned to work in a town post-office where telephone work was done, and there was a strong protest by his colleagues in the office, who thought they were running some risk by using the telephone mouth-piece after him. The matter was referred to Dr. Wilkins, who had had charge of the patient, and he said the man was not infectious and could not infect the telephone. In any case the breath was not infectious except in extreme cases, and then the only fear was from coughing into the telephone. Dr. Lister quite agreed with Dr. Wilkins, and the secretary pleaded for a more charitable treatment of patients before, during, and after their residence at a sanatorium. Women members of the society had equal rights with men members, and five women members for whom the society had obtained treatment had cost the society from £40 to £76 each. He concluded by thanking the Post Office Department for the sympathy and help it had given to the society. After adoption of the reports of the secretary and the treasurer, a new rule was discussed and finally carried, to the effect that officers in the employ of the Post Office might become members of the sanatorium society by allowing a deduction of "one shilling or more" from their salaries every six months, which amount would go to the society. It was also arranged to hold a conference every two years subject to an annual statement. Mr. C. H. Garland was reappointed secretary and Mr. H. Trollope treasurer, and a committee of management was appointed containing representatives from the chief towns of the kingdom.

THE MIDWIVES ACT.

THE position of medical practitioners under the Midwives Act, 1902, was discussed at two recent meetings of the Midland Medical Union. Attention was called to the fact that during successive quinquennia from 1881 the birth-rate had declined as follows: 33.5, 31.4, 30.5, 29.3, 28.1, while the rate for the last two years was 26.3. The members of the Union, feeling strongly that it is the duty of the State to ensure that the highest and best care shall be given to those women who are producing the future race, adopted at their meeting on April 8th the following resolution,

which has been forwarded to the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act:

That it should be illegal for a midwife to attend a woman in her confinement unless a medical practitioner is retained, so that he may be called in in case of abnormality or disease in connexion with parturition. When the wages are less than 18s. a week and 2s. per child under 14, the public assistance authority shall, if requested, issue an order requisitioning the services of a medical practitioner. This order shall entitle the medical practitioner to a fee of 5s. for a preliminary examination and advice on the preparation for labour, and to adequate remuneration in the event of his having to take charge of the case on account of abnormality or disease in connexion with parturition.

Medical News.

DR. ARRIGO TAMASSIA, Professor of Forensic Medicine in the University of Padua, has been created by the King of Italy a Senator of the Kingdom.

THE King has conferred the new Territorial Decoration on Lieutenant-Colonel John Daniel Lloyd, of Chirk. Dr. Lloyd has served for thirty years in the Shropshire Yeomanry.

THE Lord Chancellor has placed the names of Dr. John M. Cuthbertson, of Droitwich, and Dr. Cordley Bradford, of Acocks Green, on the Commission of the Peace for Worcestershire.

THE Hon. John McCall, M.D., who has been appointed Agent-General for Tasmania, is expected to take up his duties in London on May 1st. Dr. McCall graduated at the University of Glasgow in 1881.

DR. F. M. SANDWITH, Gresham Professor of Physic, will deliver four lectures at Gresham College, E.C., on April 20th, 21st, 22nd, and 23rd, at 6 p.m. on each day. The first three lectures will deal with cancer, and the fourth chiefly with certain tropical and subtropical diseases.

A MEETING of the directors of the International Cancer Research Association will be held at Berlin during the Congress of the German Surgical Society. Among the proposals to be considered is a scheme of international statistics as to the prevalence of cancer, and as to the results of operations for its cure.

At a special meeting in March the Brighton and Sussex Medico-Chirurgical Society passed a resolution to the effect that it was no part of the duty of a hospital staff to fill up medical certificates for out-patients, and that it was not advisable that such certificates should be given.

DR. A. S. BOSTOCK, on the occasion of his leaving Chichester, where he has practised for many years, was the recipient of a very gratifying testimonial signed by a large number of residents. The testimonial, which was accompanied by a cheque, was presented by Sir R. Turing on behalf of the subscribers.

WE are requested to state that forms of application for the admission of children into the Lord Mayor Treloar Cripples' Home and College, Alton, Hants, can be obtained from Sir William Treloar, 122, Mansion House Chambers, London, E.C. Special consideration is given to applications for the admission of children suffering from tuberculous disease of the bones and joints.

At a missionary exhibition to be held at the Agricultural Hall in June, a section dealing with outfits suitable for travellers in the tropics is to be provided by the Livingstone College, Leyton. It is desired to make a special feature of appliances intended to protect travellers and residents in hot climates from the bites of mosquitos and other insects; and Dr. C. F. Harford, the President of the College, will be pleased to hear from any one interested in the subject.

THE Shakespeare memorial service at Southwark Cathedral, which has been arranged by a committee of which Dr. R. W. Leftwich, 125, Kennington Park Road, S.E., and the Rev. Canon Thompson, D.D., Southwark Cathedral, London Bridge, S.E., are honorary secretaries, will take place at 3.30 p.m. on Friday next, April 23rd. After the anthem the Post Laureate will recite an ode to Shakespeare's birthday, and Mr. Forbes Robertson will give an address on Shakespeare. The service will conclude with the singing of a hymn specially written for the occasion by the Rev. Canon Rawnsley. The collection will be given to the fund now being raised for the erection of a Shakespeare memorial in the cathedral, the poet's old parish church; this it is expected will cost about £650. The decoration of the Shakespeare window in the cathedral with the flowers of Ophelia and Perdita has been undertaken by Miss Ellen Terry, with the assistance of other Shakespearian actresses.

British Medical Journal.

SATURDAY, APRIL 17TH, 1909.

CATGUT AND TETANUS.

We publish in another column (p. 948) an account by Mr. W. G. Richardson of certain cases in which tetanus supervened after surgical operation. On two occasions—in October, 1907, and again in January of the present year—this result followed operations performed by the author, who has in consequence been anxious to ascertain whether other surgeons have had similar experiences. He has been enabled to collect notes of 21 such cases, and finds that in 18 of them the patients died. All except one of the cases occurred during the past three and a half years, and in all of them catgut was used for ligatures. With the exception of two, the operations involved opening of the peritoneal cavity. Another point, on which the author lays stress, is their geographical distribution. Eleven occurred in Northumberland, 6 in Ireland, 2 in Scotland, 1 in South Shields, and 1 in Manchester. In 15 of the cases bacteriological examinations were made, and in 5 there were found bacilli "resembling" the tetanus bacillus; but in the 3 instances in which the bacilli were tested upon animals the experiments proved negative.

These, we take it, are the main facts, and we agree with Mr. Richardson that they do not warrant any categorical conclusion. In calling attention to the cases which he has collected, his main object has been to elicit further information from other sources. It is desirable to know whether other surgeons have recently met with tetanus following operation, and, if they have, what evidence they have obtained as to the mode in which the infection was introduced. To such information we shall be glad to give publicity, and we hope that it will furnish sufficient data for forming a definite opinion. In the meantime we confine ourselves to a few comments on the statements and suggestions which Mr. Richardson offers.

From their clinical aspects, the cases he records were, without hesitation, diagnosed as tetanus, and therefore there is a very strong presumption that they were caused by the tetanus bacillus. It is most probable that the bacilli were introduced during the course of the operation; and as catgut, notoriously difficult to sterilize, was used in every case, suspicion naturally fastens on this substance. The bacteriological examinations which were made were either negative or inconclusive; but some of them were admittedly incomplete, and the details given regarding the rest are insufficient to warrant us in assuming that all the resources of bacteriological technique were exhausted before a negative report was sent in. The tetanus bacillus is not an organism which multiplies and disseminates freely in the tissues, and therefore attempts to raise a culture of it from suspected tissue often fail. In the cases in

which the surgeon's disinfectant-soaked catgut was tested one would like sufficient details to justify the opinion that the examinations, when negative, were exhaustive enough to establish beyond reasonable doubt the absence of living tetanus spores from the substance of the ligature.

Mr. Richardson suggests that the large preponderance of abdominal cases may be an indication that the catgut was not responsible for the infection, his argument being that two-thirds of the operations in which catgut is used do not involve the peritoneum, and that therefore the abdominal cases followed by tetanus ought to be in the minority if catgut were the responsible agent. But it is dangerous to generalize about percentages when the total number of cases is so small; and there are other factors to consider, such as the relative resisting powers of different tissues against bacteria and the greater facilities for keeping surface wounds in an antiseptic condition throughout the healing process. If we are to follow Mr. Richardson's theory, we must place the two non-abdominal cases—a varicocele and a scirrhus of the breast—in a class by themselves, and seek for the other nineteen cases an explanation which would not be appropriate for these two. Such a separation of the total twenty-one cases into two distinct classes does not appear to be warranted by the evidence before us; the more plausible assumption, in the absence of definite reasons for a contrary view, is that all the cases were due to the same or similar causes.

Catgut, as every schoolboy knows, is made from the intestine of the sheep, and consists of the submucous cellular coat from which the mucous membrane has been removed by scraping. In its preparation for surgical purposes Lord Lister had in view three requirements: first, that it should be aseptic; second, that it should be sufficiently strong for the purpose for which it was to be used; and third, that it should not be absorbed either too soon or too late. Many ways of achieving these ends have been devised, but we may be permitted to doubt whether any one of them is superior to that first propounded, we believe, by Lord Lister in his address to the Clinical Society in 1881, and more recently minutely described by him in the note on "the preparation of catgut for surgical purposes," published in this JOURNAL last year.¹ The method is one which provides for the combined action on the catgut of solutions of corrosive sublimate and chromic acid. The bacteriological evidence advanced by Lord Lister seems sufficient to establish that the method destroys not only such organisms as the streptococcus but also the spores of anthrax—an observation which recalls the fact, noted by Lord Lister in his contribution to the *Virchow Festschrift*, that von Volkmann had seen anthrax result from the use of a catgut ligature, prepared no doubt from the intestine of a sheep that had died of that disease. Brown Miller, writing in the *John Hopkins Hospital Bulletin* in 1900, said that "anthrax in catgut has caused in more than one reported case a fatal infection. Within the past six months a Chicago surgeon has told me of two of his patients, who were operated upon the same day, dying of anthrax infection which was caused by the catgut used in the operation." Lord Lister, however, is careful to point out that, while the substance of the catgut thus prepared is "not only aseptic but powerfully antiseptic, its dry surface is liable to contamination by contact with septic material, and it is essential that, before being

¹ BRITISH MEDICAL JOURNAL, 1908, vol. i. p. 125.

"used, it was washed with some trustworthy germicidal liquid. My practice has been to put the catgut, like the instruments, in 1 to 20 solution of carbolic acid about a quarter of an hour before the operation is begun. Any of the catgut that remains unused upon the reel may be afterwards kept in a similar solution for any length of time without disadvantage. The essential precaution of purifying the surface of the catgut is, I fear, sometimes overlooked, the result being occasional suppuration attributed to defect in the ligature, while it is really the fault of the surgeon." With regard to tetanus attributed to catgut, Kuhn and Rossler² collected reported cases in which tetanus had been traced or attributed to catgut. We are informed that in all recent cases of tetanus after ligature of haemorrhoids catgut was the material employed. Recently Dr. Reuben Peterson of Ann Arbor, Michigan, recorded a case in which tetanus developed on the twelfth day after dilatation and curetting of the uterus, with shortening of the round ligaments, by Alexander's method.³ The patient recovered under the use of chlorotone. Suspicion was directed to the catgut used for the plastic operation on the round ligaments, but careful bacteriological examination by an expert failed to reveal the presence of any micro-organism. At the corner of one incision which had otherwise healed well there developed a minute blister which contained the staphylococcus, but the tetanus bacillus could not be isolated. It will be observed that Mr. Richardson in his paper attaches high significance to the late Professor Hamilton's work on "looping-ill" and other diseases of sheep. We have no wish to disparage that most genial and enterprising of pathologists; but when a pathologist, however eminent, endeavours to open up new ground, our first attitude must be one of caution, and we must wait full and independent confirmation of his data and his theories before accepting them as definitely proved. We do not think that the late Professor Hamilton's theories, interesting though they be, have gained sufficiently wide acceptance to substantiate the hypothesis, put forward by Mr. Richardson, "that the disease which we call post-operative tetanus is not tetanus at all, but one of the sheep diseases." However this may be, Mr. Richardson's paper raises a question of considerable practical importance. Such a sequence of events as he describes is distressing to the individual surgeon and disconcerting to all.

JEWS AND ALCOHOLISM.

THE abuse of alcohol has so much influence in determining the moral, mental, and physical deterioration of those who yield to it that it is not surprising to find that the tendency of various races in this direction has been found worthy of serious study. Dr Cheinisse⁴ has recently discussed the question whether the Jews of the present day may be considered immune from this vice. No statistics being available in any country which would enable the quantities of alcoholic liquors consumed by Jews and by the rest of the population respectively to be compared, Dr. Cheinisse sought to establish the greater temperance of the Jew by figures which prove his comparative immunity from those diseases and vices

most generally supposed to be connected with alcoholic excess.

The few figures which exist regarding the direct effects of intemperance are very significant, as far as they go. In this country it is rarely, if ever, that the death of a Jew is registered as due to alcoholism. In New York, where the number of the Hebrew population of Russian origin is very considerable, the deaths returned from alcoholism in one year formed 0.42 per cent. of the total deaths in that city, while among those who were children of Russian or Polish mothers the percentage from the same cause was only 0.13. The same proportion represents the ratio of cases of alcoholism and diseases directly due to it among total cases admitted into the chief Jewish hospital in New York, whereas in the Boston City Hospital, cases of alcoholism formed 3 per cent. of the total.

It seems, however, scarcely necessary to seek for definite statistics to prove that Jews are, as a race, peculiarly free from the vice of intemperance. It is a striking fact that of the many hundreds of Russian immigrants for whom situations have been found during the last fifteen years by a charitable organization in London not one has ever been dismissed for drunkenness.

It is to be noted that it is the excessive and not the moderate use of alcohol which is avoided by Jews, and while among them a dipsomaniac is a rarity, on the other hand a total abstainer is almost unknown. Indeed, the drinking of a special wine is a portion of the ritual in most of those domestic religious functions which form so large a part of the life of the observant members of the race. Therefore, in considering the influence which habitual temperance may have had on their physical condition, we are observing a people who are no fanatics for abstinence, who habitually consume wine in small quantities, and who unhesitatingly take alcohol in any form and quantity in case of illness or emergency.

The difficulty of estimating their number, and the consequent uncertainty of the statistics, makes it difficult to establish the truth of the general belief in the comparative longevity of the Jew; but all the evidence goes to show that the death-rate is distinctly below the local average. In Stepney, which is largely inhabited by Jews, the death-rate in 1907 was only 15.8, although the birth-rate was one of the highest in London. In the Abstract of the Twelfth Census of the United States the death-rate in cities for different classes of the population is compared, and that for children of Russian and Polish mothers (mostly Jews) is shown to be lower than that of any other group. Similar facts have been observed in those wards of New York where the Russian immigrants mostly reside. Again, in Prussia, where an estimate of comparative Jewish mortality was recently made, it was said to be little more than two-thirds of the average rate; but this difference is so great that it seems improbable that the figures are correct. In all the countries mentioned it should be noted that the death-rate varies most from that for the general population when persons under 15 years of age are considered.

It must always be remembered that alcoholism is responsible indirectly for many evils with which at first sight it would seem to have no connexion. Hospital practice shows so many cases of disease of nerve centres, of kidneys, liver, or arteries due to alcoholism that it seems to the student that all heavy drinkers must die at an early age, victims of their habits.

² *Deutsche Klin. Therap. Wochenschrift*, 1905, Nos. 46, 47.

³ *American Journal of Obstetrics*, April, 1909, p. 558.

⁴ *La Semaine Médicale*.

More extended experience convinces the practitioner that, perhaps unfortunately, this is by no means the case.

On the other hand, private practice, especially among the working classes, brings to light other, more insidious, evils which have a more profound influence on the health and well-being of the community than the mere death of the drunkard would produce. Greatest of these evils is the poverty which results when the wage-earner of the family spends a large portion of his earnings on drink; improper and insufficient food lowers the resisting power of the whole family, and renders every one of them an easy prey to many forms of disease. Thus it is to be expected that comparative sobriety would have for its chief result a greater general healthiness of the family, which would show itself in a lesser mortality in early life.

It is not possible to estimate the infantile mortality among English Jews in the absence of any figures showing the number of Jewish births, but all those having any knowledge of this community are agreed that the mortality is lower than the average. Some support for this may be found in the figures for Stepney, where the infantile mortality in 1907, 119 per 1,000 deaths, was the lowest of the Eastern London boroughs, though the general conditions of life afford no explanation. The large Jewish population in the United States offers a better field for investigation, and various calculations dealing with this subject made by Dr. John Billing were published as part of the Eleventh Census. The figures prove beyond doubt the lower mortality among Jewish children, it being estimated that out of 100,000 such infants 84,000 would be living at the age of 5, while out of the same number of the infants of Massachusetts only 73,000 would be surviving at that age. The same fact has been observed in Russia, where it has been noted that in the pale of settlement about 74 per cent. of Jewish infants survive their first year, as against about 60 per cent. of the children of the Christian population. The report of the Registrar-General for 1906 gives 9.2 per 10,000 living as the death-rate for London from the four principal infectious diseases of childhood—measles, scarlatina, diphtheria, and whooping-cough. The deaths from those diseases during the same year, as noted by the Burial Society of the United Synagogue, were 114, and after estimating the population of which the deaths are recorded by this society, the rate would appear to be slightly lower, although, of course, no accurate figure can be arrived at, as the estimate of population is only approximate. A small difference would, however, be important, for there is no doubt that the age distribution of the Jewish community varies greatly from that of the general population, there being a far larger proportion of children in the former group. The figures for New York show a much lower death-rate among Jewish children from diarrhoea and diphtheria, while from scarlatina it is almost equal to, and from measles rather higher than, that for the general population. For children under 15 years of age, those born of Russian and Polish mothers have the lowest mortality of any group of children in the United States.

It was recently pointed out in the BRITISH MEDICAL JOURNAL that the mortality from tuberculosis among Jews in both London and New York was far less than among the general population, the death-rate among the former being only about two-thirds of the estimated rate for this disease, in spite of the fact that in

both of these cities the Jewish immigrants are mostly living under most unfavourable conditions. The influence of chronic alcoholism in predisposing to consumption is so generally admitted that it is probable that the comparative immunity may be in some part due to greater temperance. At the same time, it must be mentioned that phthisis has become considerably more frequent among this portion of the population during the last few years.

There is no sufficient reason for thinking that cancer attacks the Semitic with any less frequency than the Anglo-Saxon race. Crude statistics would appear to give grounds for a belief that this is the case, but the fact, pointed out above—that the former population contains a far larger number of young and a proportionately smaller number of old persons—supplies the true explanation. In the United States children of Russian and Polish mothers give almost the highest cancer-rate for ages over 65.

The deaths from diseases of the circulatory system are in England proportionately fewer among Jews, but this does not seem to obtain in other countries; in the United States the mortality is apparently greater, while in some Continental countries for which comparative statistics are available the incidence of these diseases is about the same.

Jews appear to enjoy a certain immunity from diseases of the urinary system. The statistics for New York show that the Jewish population has a lower mortality than any other nationality from this class of disorder. The direct effect of alcohol in the causation of chronic nephritis is probably an explanation of the lesser prevalence of these diseases among the more temperate races.

No trustworthy figures exist to show the comparative frequency of syphilis, but all those who see much of this disease are of opinion that it is much less common among Jews. Their comparative temperance would obviously have no small influence in determining this immunity, though circumcision is probably an important factor.

On the other hand, the mortality among Jews from diseases of the respiratory organs other than pulmonary consumption is above the average. This may in part be due to deaths from bronchitis among children, of which the proportion is so large. It is probable, however, that there is a distinctly increased tendency to this form of disease.

Nervous disorder is, however, the form of malady to which the Hebrew is far more prone than the races among which he lives. This is marked, whether the graver forms of degeneration of the central nervous system be considered or the milder manifestations of neurotic disturbance. It is also remarkable that although alcoholism occupies the first place as the causative influence of insanity, and although it is rarely, if ever, that the admission of a Jew to an asylum is noted as being due to this cause, still the number of Jews certified as insane is far larger than their proportion of the population will account for. No doubt this may partly be traced to the fact that for generations they have suffered from persecution, and also, living in towns, have been obliged to gain a livelihood by occupations leading to mental rather than to physical exhaustion. Various other explanations may be suggested of this decided tendency to nervous disorders, which is not only evinced by statistics, but has been observed by all physicians who have a large Jewish clientele. The fact may serve to remind us how many are the influences

besides the one dealt with here which have combined to mould the destinies of the Jewish people.

The idea referred to by Dr. Cheinisse that suicide is rare among Jews is not quite in accordance with the facts at present, although in former times self-destruction was apparently less frequent among them than among the surrounding population. The comparative suicide-rate varies greatly in different countries, but it is high in most German states, the death-rate in Prussia from this cause being 32 per 100,000 Jews, as against 20 for the same number of the non-Jewish population. It is, of course, scarcely surprising to find that the curve of mortality from suicide follows the same line as that for insanity and for nervous diseases generally, and if temperance could not protect the Jew from the ravages of mental disease it could not be expected to have much influence in lowering the mortality from suicide.

In addition to diseases of the nervous system, diabetes and diseases of the digestive organs cause a disproportionate mortality. With regard to diabetes, this may probably be traced to the general nervous instability; it may, however, be noted that those who abstain to a great extent from alcoholic liquors often develop an inordinate taste for sugar; the love of sweets is very marked in Semites, but it would be dangerous to assume that this has any causal relation to the prevalence of diabetes among them. It should be observed also that Jews, as a rule, engage in sedentary pursuits and are not much inclined to active exercise, this may perhaps account for the prevalence among them of diseases of the digestive system.

It will be seen from the foregoing short analysis of Jewish vital statistics that the young of this race are more healthy and show a greater resistance to disease than the children of the surrounding population, and this is perhaps the most definite fact which can be connected with their habitual temperance. Other causes may have contributed to the result, but it is scarcely to be doubted that the sobriety of the parents has led to the development of a more healthy offspring. The constitution of the parents has not been impaired by the injurious effect of alcohol, and the comfort and happiness of the home has not been destroyed by the carelessness and disorder which is so surely produced by drink. When the attempt is made to trace the beneficial influence on the adult of temperance, as exemplified by the Jew, the problem becomes complicated by an infinite number of other circumstances which affect the lives of these people, and it is difficult, if not impossible, to decide how far any one influence has been the determining cause of any special immunity. Still more difficult is it to appreciate by how much other unfavourable conditions of life may have served to neutralize the beneficent effects which moderation in alcohol would otherwise have produced.

The Jewish population, both in this country and in the United States, is composed of two very unequal portions. The smaller part consists of those who have been born in the country, or have resided in it for many years; the larger part consists of recent immigrants, mostly in extreme poverty, badly fed, housed in overcrowded tenements, and the victims of sweaters, working under most insanitary conditions. The two classes differ in other respects, the recent immigrants being far more observant of their dietary laws and peculiar customs, while the older residents are more inclined to assimilate their mode of life to that of their neighbours. No doubt if separate vital statistics could be had for these two

classes they would be found to differ; but in the only figures obtainable the returns are swamped by the facts relating to the immigrants, and their unhappy condition is no doubt responsible for some of the unfavourable figures.

ANTIVIVISECTION AND WOMAN SUFFRAGE.

SPEAKING at Clifton on April 2nd, Mr. Stephen Coleridge (according to a report published in the *Bristol Mercury* of April 3rd) said that one thing which was very often forgotten by the vivisectioners of England and those who supported them was that they did not merely inflict long and painful suffering—is this a Coleridgian subtlety, or does he believe that there is suffering which is not painful?—on animals, but also an immense amount of untold suffering on human beings. There were, he went on to say, thousands and thousands of kind-hearted people in England to whom the misery that was going on at the present time in laboratories by the torture of poor defenceless creatures rose up between them and their happiness in life, and deprived them of a great deal of that to which they were entitled. He thought it was not improbable that the one really good thing that might come from "female"—in self-defence we wish to point out that the word is his, not ours—suffrage might be that the women of England would bring that suffering before the public and force upon Parliament a measure to provide for better protection of animals, not only in the laboratories but in other ways.

Mr. Coleridge's picture of the "painful suffering" and "torture" inflicted on animals does greater credit to his imagination than to his regard for truth. If the mass of evidence given before the Royal Commission on Vivisection by vivisectioners, and more especially by antivivisectioners, has not convinced him that these things are nothing more than nightmares of overheated minds, he is beyond the reach of argument. As for the sentimental sufferings for which he asks our pity, is it possible that any reasonable person can believe that they can be weighed in the balance against the incalculable amount of real pain from which sufferers from disease have been, and will continue to be, delivered by means of vivisection? Mr. Coleridge looks to woman suffrage to advance the cause which he champions. It is true that some of the militant suffragists are women of the type of Miss Frances Power Cobbe, who said she loved animals by nature, and human beings only by grace. But we doubt whether women in general prefer the welfare of animals to that of their children. When they are philofoists their sentiment is apt to express itself in strange ways. We have known a lady who was an ardent antivivisectionist, and who kept pet cats without regard to the comfort of her neighbours. Yet to keep them, as she said, from roaming, she had them castrated! Sensible women who wish to have a vote will scarcely be grateful to Mr. Coleridge for his suggestion that the really good thing that would come of their having it would be the promotion of a particularly silly and mischievous agitation.

In the same speech Mr. Coleridge dwelt on the inadequacy of the inspection of laboratories under the present Act. He is reported to have said that "in the recent Royal Commission, the evidence of which was now closed, the officials from the Home Office told the Commissioners in cross-examination, firstly, that they never made surprise visits to laboratories, and secondly, in reply to the question as to what were

"the instructions given to them when they took office, the answer given was 'not to act as detectives.'" The first of these statements is false, and the second is misleading. With regard to surprise visits, it might be inferred that he had got the information from the minutes of evidence given before the Royal Commission. But any one who will take the trouble to refer to these minutes will find that in the evidence of Mr. W. P. Byrne, Principal Clerk of the Home Office, it is implied—see particularly Questions 224, 225, and 226—that surprise visits are paid by the inspectors. Mr. Byrne's replies on this subject must be read together with those of Professor Thane, who said in reply to Question 441 that he paid visits of inspection almost always without notice; of Sir James Russell, who said in reply to Question 553 that he very rarely gave notice of his intention to visit; and of Sir Thornley Stoker, who said in reply to Question 779 that he paid surprise visits, and had never found anything irregular, or to complain of. The testimony of these officials is borne out by that of Professor Gotch, who said he was visited three or four times a year, and was often not in his laboratory at the time because he did not know the inspector was coming; and of Sir Victor Horsley, who said that for the last seventeen years the inspector had invariably paid surprise visits to his laboratories. With regard to the instruction, said by Mr. Coleridge to be given to the inspectors, that they were not to act as detectives, one would gather that this was a regular part of the administrative routine. How far this is from being the case is shown by Professor Thane's reply to Question 1085, that he remembered very well reading in minutes that were written once that the inspector was not a detective, but he had never had anything definitely of that kind given him as an instruction! Apart from this, however, it is surely natural enough that the Home Office, which is composed of gentlemen, should think it undesirable that those whom they appoint to inspect the scientific work of men who are fulfilling the highest duty to humanity should adopt the methods of the private inquiry agent. Mr. Coleridge would probably, like Sir George Kekewich, prefer to look through the keyhole; but he would learn nothing more there than he already has every opportunity of learning by a less dishonourable means.

THE APPLICATION FOR A CHARTER.

As already announced, the Privy Council gave notice on February 15th that it had referred the petition from the British Medical Association praying for the grant of a charter of incorporation to a committee of the Lords of the Council, and further gave notice that all petitions for or against such grant should be sent to the Privy Council office on or before April 3rd. The Privy Council has transmitted to the British Medical Association for its consideration copies of all petitions against the grant of a Charter, or asking for modifications in the draft as submitted, received by it on or before the date mentioned. These petitions are from the following eight bodies: the Royal College of Physicians of London, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of England, the Royal College of Surgeons of Edinburgh, the Society of Apothecaries of London, the *Senatus Academicus* of the University of Edinburgh, the British Medical Benevolent Fund, and the Society for the Relief of Widows and Orphans of Medical Men. The Privy

Council has received in addition a petition from certain Branches and members of the British Medical Association, signed by the President and Secretaries of seven Branches, and another petition in very similar terms signed by certain members of the British Medical Association to the number of 603, resident in various parts of the United Kingdom. All the petitions have been referred by the Chairman of Council to the Organization Committee, and this Committee is preparing categorical replies for the consideration of the Central Council of the Association.

THE LATE SIR DONALD CURRIE.

SIR DONALD CURRIE, G.C.M.G., LL.D., who died at Sidmouth in the early hours of April 13th, was a man well known in the shipping world as the head of the Union-Castle Company. He was, however, not only one of the pioneers of the mercantile marine, but for many years represented West Perthshire in the House of Commons; and, moreover, was one of those philanthropists who, working unostentatiously, furthered many schemes for the welfare of his fellow-creatures. Of late years he had interested himself in the needs of the Universities of Edinburgh and Belfast, and only the other day defrayed the expense of restoring the Cathedral of Dunkeld. A little more than five years ago Sir Donald Currie lent his support to the movement which has resulted in the incorporation of University College, London, in the reorganized University of London. To carry out this scheme it was necessary to find funds for the erection of a school of final medical studies in connexion with University College Hospital, and for this purpose Sir Donald Currie gave a sum of £80,000. As if this act of generosity was not sufficient he added a sum of £20,000 for the erection of a nurses' home and a maternity students' house in connexion with the same institution, and gracefully added a further sum of £2,500 as a gift from his daughters to furnish the latter buildings. When we consider the straitened circumstances into which medical education in London has fallen, such generosity deserves the warmest thanks and approval. Sir Donald Currie, though well aware of the necessity for rich men to give of their wealth towards the maintenance of the hospitals of London and elsewhere—a duty to which he again and again responded—was none the less keenly alive to the necessity for providing support for the medical schools of the metropolis—institutions whose maintenance is so important to the public at large. Though, as he had stated publicly, there might be some reason to hesitate to provide funds for hospitals, which he considered should receive support from the rates, there could be none when the needs of the medical schools were considered. He looked upon these as technical institutes of the greatest importance to the capital of the Empire, and in the absence of Government subventions, he felt it was the duty of those who could give help to do so until the time came when the Government realized that medical schools, which form an important department of all universities, should, like every other technical institution, receive proper State support. Sir Donald Currie was keenly alive to the necessity for supporting movements which had as their object the advancement of medical knowledge; the problems of disease, no less than high finance and politics, were readily grasped by his acute intellect, and at once secured his sympathy and practical support. To him the present state of medical education in this country was a matter of serious concern, and he hoped that the time would soon come when the medical teachers, like those of any other department of learning, would

receive adequate salaries from endowments. His munificent gift for the advance of the interests of the University of London was a practical expression of his cherished views. To him it seemed a remarkable state of affairs that whilst on the Continent medical studies receive the support of the various Governments, whether monarchical or democratic, and in America almost fabulous endowment at the hands of its enlightened rich, in London, with its unequalled opportunities for the investigation of disease, medical studies were cramped, and the hospital and medical school teachers ruthlessly sweated in the interests of the public at large, by a system which left the support of the schools to the more or less fortuitous support of a comparatively few medical students. Sir Donald Currie's generosity will always stand as a protest against this state of affairs.

PREVENTION OF PAUPERISM.

DR. McVAIL, County Medical Officer for Stirlingshire and Dumbartonshire, the author of the Report on the methods and results of the present system of administering indoor and outdoor medical relief under the Poor Law system, an account of which was given in the JOURNAL of April 3rd, page 855, initiated a discussion in the rooms of the Royal Philosophical Society of Glasgow on the Report of the Poor Law Commission and "Medical Aspects of the Prevention of Pauperism." In the course of his remarks Dr. McVail said that in his inquiry, which was wholly confined to England and Wales, his investigations had largely related to the prevention of future pauperism, so far as such prevention depended on medical work. The four millions sterling spent annually on outdoor relief in England was entirely without medical supervision. As regards the medical relief of adults, every encouragement was being given to the spread of phthisis in pauper homes owing to the want of co-ordination of the Poor Law and public health work. The creation of larger administration areas was a fundamental requirement in any remedial scheme, and that reform, which was in accordance with the recommendations both of the Majority and Minority Reports, being once accomplished, some points in dispute between the reports became of less moment than the reports themselves would indicate. Whatever the new authorities might be, the prevention of pauperism should be the main object, and not merely the relief of existing destitution.

PERFORATION OF UTERUS AND LACERATION OF INTESTINE BY PLACENTAL FORCEPS.

AN instance of very grave injury inflicted during the emptying of a uterus for haemorrhages in the second month of pregnancy was recently recorded by Dr. Ralph Waldo at a meeting of the New York Obstetrical Society.¹ A woman, aged 24, the mother of a child a year old, ceased to menstruate in September, and was troubled with uterine haemorrhage during the third week in November. Her doctor determined to empty the uterus. The bowels were thoroughly cleared by a cathartic followed by an enema. The bleeding came on very severely before the appointed time for the operation, so that the patient was at once put under chloroform and the uterus emptied with the aid of a curette and placental forceps. The instrument was accidentally pushed through the uterus, and the doctor admitted that when it was pulled out 3 ft. of intestine came with it. There was profuse haemorrhage, and the bowel was pushed back into the uterus, which was packed with iodoform gauze. Dr. R. Waldo transferred

the patient to a hospital where at once, on November 20th, 1908, he opened the abdominal cavity, within five hours of the injury. A rent 2 in. long ran from the right round ligament towards the median line across the anterior surface of the fundus. It was bleeding freely, and was closed with four deep catgut stitches and a continuous suture. The large intestine was found torn completely across at the junction of the sigmoid flexure with the rectum, and three-quarters of the descending colon had been forcibly drawn through the rent in the uterus by means of the placental forceps. It had retreated entirely into the abdominal cavity and was beginning to slough. There was much blood, but only a little of the contents of the bowel, extravasated into the peritoneal cavity. The entire sigmoid flexure and about three-quarters of the descending colon were resected, the colon above being united to the rectum with a Murphy's button, reinforced by a continuous Lembert suture of fine silk. As the splenic flexure was not held up by its peritoneal connexions as firmly as usual, there was no strain on the united ends of the bowel. A Mikulicz drain was introduced and the abdomen closed with catgut and silkworm-gut sutures. The drain was removed on the fifth day, when the bowels moved spontaneously, and rather obstinate diarrhoea followed. The Murphy's button was extracted from the rectum with forceps on December 1st, and the patient was discharged from the hospital cured on December 22nd. This case teaches the value of promptness after the occurrence of an obstetric accident. There is reason to believe that this particular kind of accident is not so rare as medical literature would lead us to suppose. In the active discussion which followed the reading of the report, several American authorities admitted that the accident had occurred in their own experience, whilst two others related how they had been called in where abortionists had lacerated the uterus, and intestine lay in the vagina. In another case a doctor mistook prolapsed umbilical cord for small intestine. The alleged resemblance of intestine, twisted spirally, to umbilical cord, has been discussed before, and Dr. Von Ramdohr referred to a trial in England in 1876, where a practitioner perforated the uterus and tore off 6 ft. of small intestine. "The celebrated Dr. Duncan" (it was really another distinguished obstetrician who appeared as a witness) swore that such an accident could have happened to him, and the practitioner was acquitted by the jury. It stands to reason that we must be very careful when using the curette, dilator, and placental forceps after labour or abortion. Experts admit that they have perforated the uterus, and that it is not always easy to recognize prolapsed intestine; hence the distinguished British obstetrician was perhaps justified in making on oath the statement above quoted, although at the time many considered that he had perhaps gone rather too far in his anxiety to rescue a professional brother from a painful position.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.*

THE April part of the *Oxford English Dictionary* carries the alphabetical rubrics from *rib* to *rom*, and the words from *ribaldric* to *romanite*. Not many purely medical terms come between these termini; indeed the words which are listed by Gould in the *Practitioner's Medical Dictionary* and those in Green's *Encyclopaedia and Dictionary of Medicine*

¹ Sigmoid Flexure and 75 Per Cent. of the Descending Colon Excised for Injury produced by Placental Forceps in an Attempt to Empty the Uterus. *Amer. Journ. Obstet.*, March, 1903, p. 478.

* A New English Dictionary on Historical Principles. Edited by Sir James A. H. Murray. Ribaldric-Romanite (volume viii) by W. A. Craigie, M.A., LL.D. Oxford: At the Clarendon Press, London, Edinburgh, Glasgow, New York, Toronto, and Melbourne. Henry Frowde. Double Section, price 5s. April 1st, 1909.

and Surgery are nearly all eponymous expressions, such as Riga's disease, Rivolta's disease, Rinne's test, and Roederer's obliquity. Yet Dr. Craigie has managed, by the inclusion of some obsolete words, to make a fair show of medical terms, and that without noting eponyms of doubtful value or slender vitality; this is another proof, if one were wanted, of the extraordinary fullness and completeness of Sir James Murray's great undertaking. As an instance of the way in which Dr. Craigie has sought out every medical phrase as well as every separate word, we may refer to "rice-water," used attributively to describe the evacuations of cholera patients. The earliest quotation illustrating this special use of the expression is dated 1866, the last year in which London suffered somewhat severely from cholera; it would be interesting to know if the term took its origin during that epidemic. Passing by "ricin," "ricinic," and "ricinol" with their verbal aroma of castor oil, the medical man will naturally turn to the word "rickets." As is well known, its etymology is doubtful. The Dictionary has the following paragraph upon it: "Whistler (1645) states that the disease had first come into notice about twenty-six years before, and was said to have been named after one who tried to cure it empirically; but others derived it from the Dorset word *ricket*—to breathe with difficulty." Glisson (*De Rachitide*, 1650), from whom Whistler obtained his information, says the disease was first noticed in Dorset and Somerset, and had only gradually extended over the south of England. His own suggestion is that the word was a corruption of Greek *payrus* or *papyrus*, the former of which he adopted as the scientific name." It is of interest to remember that the disease was known abroad as the English disease. It is also interesting to find, from the illustrative quotations given by Dr. Craigie, that the word was soon employed in a figurative sense, for Fuller, in his *Worthies* (1661) has the sentence: "Hospitals generally have the Rickets, whose heads . . . grow over great and rich whilst their poor bodies pine away and consume." Let all hospital managers beware of this rickety end! Butler also, writing about 1681, affirmed that "Multitudes of Reverend Men and Critics Have got a kind of intellectual Rickets." Rickets, it may be borne in mind, is also a local name for staggers in sheep. *Rictus*, *rigor* (including *rigor mortis*), and *rodent ulcer* are defined and illustrated with sufficient fullness; and the editor finds room for a paragraph telling what *rider's bone* is, and another to illustrate the meaning of *ring finger* or "medicinnall finger." Another word now obsolete or used only dialectically is *rim* in the sense of a membrane, pellicle, or caul; thus, the *rim of the belly* is the peritoneum, as the reader of Raynalde's *Byrthe of Mankynde* soon finds out. Cooper, in his *Thesaurus*, published in 1565, defines ascites as "when betwene the rimme of the beally and the guttes is gathered . . . much watry humour." Shakespeare also says: "I will fetch thy rhyme out at thy throat, in droppes of crimson blood." The word "*rim-burst*" seems to have been in common use in Scotland and the North of England; it has the meaning of hernia or rupture. *Rim*, with this meaning, seems to have etymological relations with the old English word *reoma*, a leather strap or thong. The use of *ridge* with the significance of the back or spine in men and animals is referred to; this obsolete meaning serves to explain the word *ridgel*, an imperfectly castrated animal, especially a ram, bull, or horse with only one testicle. The explanation is that the testicle is supposed to remain near the animal's back instead of descending into the scrotum. *Ridge-bone* or *rig-bone* is the almost obsolete word for

the spine. Reference is also made to the obsolete meaning of *rift* as a crack in the skin or an eruption from the stomach. *Ringworm*, of course, is carefully defined and copiously illustrated by quotation.

CYTOLOGY.

THE number of new *Archives* which are now appearing in Germany shows the extraordinary and widespread interest in the progress of the medical sciences. Germany seems to be the publication place of scientific literature for the world; the German scientists possess the patient faculty of laboriously analysing and serving up the researches published in each subject, and the workers in other countries buy the German compilations, and we have reason to be thankful that there is a nation which will crush the quartz from which they can obtain the gold. The most recent of the *Archives* is one devoted to cytology and edited by Dr. Richard Goldschmidt. The object of this publication is to bring together the original work on the structure and life-history of plant and animal cells. The researches may be published in German, French, English, or Italian. In the first four numbers, which contain many excellent plates, we find, among others, articles on the new problems of the cell theory, by R. Hertwig; on the cause of sterility of hydrids, by G. Tischler; on experimental researches on cells, by M. Popoff; and on the development of the germ-cells in the parthenogenetic generations of certain insects. The tenor of most of these papers seems to be towards the microscopical examination of minute structural details in the cells, the arrangement of the nuclear chromosomes, etc. Such morphological examination will not by itself carry us far. What is wanted is the development of micro-chemical methods of study and the direct attack on those physico-chemical problems which underlie the structural arrangements seen in hardened and prepared specimens. The microscopist of the future must be a first-class physical chemist. The researches of M. Popoff have been conducted on physico-chemical lines. He has studied on certain infusoria the growth of cytoplasm and nucleus and the process of division, under varying conditions of temperature at 25° C. and 14° C. During the process of growth cytoplasm and nuclear plasm increase proportionately, then suddenly the volume of nucleus becomes larger in volume, and the division of the cell results. When Popoff experimentally cut off a mass of cytoplasm from the infusorium at this stage the division proceeded without change, but if he did the operation just before the nuclear enlargement this, and in consequence the division of the cell, were delayed. The experiments showed that the chromatin (nucleo-proteid) was increased by chemical changes in the cytoplasm before division.

MEDICAL AUTOMOBILISTS.

A BREACH of speed limit by a medical automobilist came under the consideration of the Kingston magistrates recently, and resulted in a decision that, although the police had acted with perfect correctness in the matter, the case should be dismissed. It was one in which the medical man concerned was returning in haste to London in response to a telephone message that one of his patients, an inmate of the wards of the London Hospital, stood in immediate need of his services. When giving evidence on behalf of his chauffeur, the medical man stated that had he not been stopped by the police he

¹ *Archiv. für Zellforschung*. Edited by Dr. R. Goldschmidt. Vol. I. Parts I, II, III, IV. Leipzig: W. Engelmann. 1908. (Roy. 8vo, pp. 1-622; 21 plates. M. 16, 21 and 11 respectively.)

would have reached the hospital in time to save his patient's life. This case, therefore, is a perfect illustration of the truth of what was said in these columns a year or two ago when a similar incident came under notice. We then expressed a belief that a medical man driving in such circumstances at an excessive speed would usually experience the truth of the old proverb, "More haste, less speed." Apart from the increased probability of his being arrested by an accident, he was liable to be stopped by a police officer, who could not always be expected to distinguish at sight the motor-car of a medical man from that of an ordinary individual. On the same occasion we expressed the view that in the general interest it was not desirable that medical men should be excepted from the speed regulations. There is an increasing number of medical automobilists, and if they received a general licence to drive at unusual rates, there would certainly be an increased risk to the general public quite incommensurate with any probable benefit to individual patients. The case just quoted is not an argument on the other side, for if the patient really died because the police stopped the surgeon, the fault was not that of the police, but of the hospital in which the patient was being treated. The fate of no patient in a large hospital in London should depend upon the presence of a medical man who has to be summoned by telephone from a place fifty miles in the country. Among other comments which this case has evoked is a letter of a remarkable character in the *Daily Mail*. The writer, in support of his contention that medical men should be excepted from the speed rules, says that on a recent occasion he was informed by his house-surgeon that he need not attend the hospital, as the patient whom he proposed to visit had ceased to breathe. It was a case of obscure brain inflammation, and, giving directions for artificial respiration to be performed, he started off in a taximeter cab forthwith. On arrival at the hospital he restored natural respiration by performing an operation which gave vent to a brain abscess; and he claims that although he travelled four miles ("in a little over ten minutes") to reach the hospital, he completed his journey and performed his operation within fifteen minutes of receipt of the information from his house-surgeon. The whole story, which is authenticated merely by initials, sounds apocryphal, and even if it were otherwise, we should not consider the general argument established by the incident.

DEMONSTRATIONS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE series of demonstrations instituted in connexion with the Museum of the Royal College of Surgeons of England will be brought to a close for the present session by three to be given by Professor Keith in the theatre of the College, Lincoln's Inn Fields, on malformations of the face and neck. These demonstrations will be given at 5 o'clock on Friday, April 23rd, April 30th, and May 7th. The Hunterian Museum has a large number of specimens illustrating malformations of the face, mouth, and neck, including a collection presented by the late Sir William Ferguson. The demonstrations have been well attended, and evidently have met a want on the part of the medical public.

MEAT WINES.

MR. D. INNES SMITH, Managing Director of Bendle Limited, is dissatisfied with the form of the correction published in the *JOURNAL* of April 3rd, p. 867, with reference to the "Meat-Port Nutrient"

sold by the company. He desires that it should be stated that the 1.4 per cent. protein there given represents about 7 per cent. of raw meat, and this is the case. He also considers that the paragraph did not make it sufficiently plain that the meat-derivative contained in the preparation is not a meat extract but nutrient meat material, and he thinks that medical men may be misled unless this is categorically stated. We have no desire either to mislead our readers or to do any injustice to the company which Mr. Innes Smith represents, and trust that the point has now been made quite plain.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Apothecaries' Hall (Ireland) and Irish Universities Act.—

In reply to Mr. Jeremiah MacVeagh, Mr. Birrell said that he had received a year ago an appeal from the directors of the Apothecaries' Hall of Ireland for compensation for the losses which they anticipated, as a licensing body, owing to the operation of the Irish Universities Act. The appeal was not one which he could recommend to the consideration of the Treasury.

The Ambulance Service of the Metropolis.—

The Home Secretary stated, in reply to Sir W. Collins, that owing to the pressure of current work he had not been able to give the report of the Committee on the Ambulance Service for London the detailed consideration which it required. He would see whether he could not deal at once with certain of the recommendations by administrative action; but he was afraid he could not hold out much hope of dealing with the main recommendations, which involved legislation, in the present Session.

The Feeble-minded in Poor Law Institutions.—

Mr. A. H. Scott asked the President of the Local Government Board if he could issue an order upon all Poor Law authorities to remove or isolate when possible all feeble-minded epileptics, inebriates, imbeciles, and lunatics from other inmates of the workhouses, as recommended in the recent reports of the Royal Commission on Poor Law, and also in the Reports of the Royal Commission on Aged Poor in 1895. Mr. Burns said that to the extent to which existing accommodation or additions to existing accommodation in Poor Law institutions might suffice for the modification of present arrangements affecting the classes to which the question referred, the powers of the Local Government Board and of the Poor Law authorities could, no doubt, be exercised in the direction indicated in the question. But for any such comprehensive treatment of the matter as appeared to be contemplated in the Reports of the Royal Commissions legislation would almost certainly be needed.

Children Boarded Out.—

In answer to Mr. Whitehead, the President of the Local Government Board stated that according to the latest returns the number of children boarded out beyond the union was 1,941. There were three inspectors of children of this class. The number of children boarded out within the union was 6,664. The duties of the boarding-out inspectors did not extend to these children. With regard to the inspection of children boarded out within the union the matter was under consideration, and he had not at present arrived at a decision with regard to it.

Inoculation against Enteric Fever in the Army.—

In answer to Mr. Lupton, Mr. Haldane stated that in the last year arrangements had been made for the voluntary inoculation against enteric fever of officers, warrant officers, non-commissioned officers, and men of the regular army at all stations at home prior to their departure for foreign service. Similar arrangements had also been made for voluntary inoculation against typhoid fever being carried out on board all troopships and in all commands, including India, where enteric fever was prevalent. Statistics on

the subject were not yet available. No arrangements had been made for the voluntary inoculation of the Territorial Force in this country. These inoculations were performed by officers of the Royal Army Medical Corps. No payment was made for the operation. The antityphoid vaccine was prepared at the Royal Army Medical College, Millbank. The sum of £63 was spent on the preparation of the vaccine last year, the amount being charged against Vote 2, subhead D.

Deaths from Beri-beri in the Mercantile Marine.—Before the Commons separated for the Easter recess a number of questions were put to the Secretary of the Board of Trade regarding deaths from beri-beri of Asiatic seamen on the ships *Avala*, *Falls of Orchy*, and *Ocean Monarch*. Mr. Tennant in each case, in admitting the deaths, said that an inquiry was held at the port at which each death took place, that the men were examined medically before joining the ships, and that further inquiries would be held on the return of the ships to this country. That the cause of beri-beri had not yet been definitely ascertained, but it was probable that bad and insufficient food might predispose to the disease. In the case of the *Avala*, six previous deaths from beri-beri on board this vessel had been reported during the last three years, and care would be taken to ascertain, on the return of the vessel to this country, whether there was anything in the ventilation, food, or conditions of employment which might have conduced to such a serious loss of life.

Aliens and Trachoma.—Last week Mr. Rupert Guinness called the Home Secretary's attention to the fact that 90 per cent. of the sufferers from trachoma at the Royal London Ophthalmic Hospital during the six months covered by the last report were aliens, and asked if, in view of the suggestion of the chairman of the hospital that such persons should be prevented from landing in this country, and of the introduction of this disease by aliens who had not been inspected at an immigration port, he would lower the number of alien immigrants carried in a non-immigrant ship. Mr. Gladstone replied that he understood that the statement mentioned in the first part of the question was made by the chairman of the Royal London Ophthalmic Hospital at the recent annual general meeting of the governors. Without altogether accepting as correct the further statement made by the hon. member, he might say that he had the point under observation, and that he was asking for further and more exact information as regards the general statements contained in the question.

Fever in Malta.—In answer to Mr. Lupton, who asked for the number of cases of Malta fever and simple continued fever respectively among the troops at Malta from 1897 to 1905 inclusive, Mr. Haldane gave the following figures:

Year.	Malta Fever.	Simple Continued Fever.
1897	279	1,275
1898	200	1,509
1899	275	1,107
1900	158	1,153
1901	252	1,059
1902	155	981
1903	404	781
1904	320	1,350
1905	643	1,199
1906	161	508

Colonel Seely promised to try and obtain similar figures for the civil population, and Mr. Haldane, in answer to a similar question as to St. Elmo Barracks, stated that there were no figures available in the War Office previous to January 1st, 1905, for individual barracks at Malta.

The Sale of Tuberculous Cows in Hampshire.—Mr. Field asked the President of the Local Government Board whether he would arrange that proceedings should be taken against Mr. Goulding for selling three tuberculous cows in defiance of the order of the Ringwood District Council. Mr. Burns replied that he had communicated with the Ringwood Rural District Council, and he found that they did not issue any order forbidding Mr. Goulding to sell the cows referred to, nor were they empowered to do so. Two of the cows were sold by Mr. Goulding to a Mr. Lewis, who subsequently had them sold at Salisbury Market. He understood, however, that Mr. Lewis was not informed by Mr. Goulding of the condition of the cows. The third cow was still in the possession of Mr. Goulding. The warning given him by the District Council related to the use of the milk from these cows for human food, or to its use as food for swine or other animals until it had been boiled. So far as he was aware, no legal offence had been committed either by Mr. Goulding or Mr. Lewis.

The Importation of Diseased Meat.—Mr. Bowerman asked the President of the Local Government Board whether he had made any representations to the United States Government respecting a consignment of diseased meat sent to this country in boxes bearing the official label of soundness. Mr. Burns replied that particulars as regards this meat had been supplied to the representative in this country of the United States Department of Agriculture, at the request of that Department, for the purpose of inquiry by that Department. In these circumstances he had not thought it necessary that formal representations should be made to the United States Government on the subject, or to ascertain the name of the firm of exporters.

Escapes from Lunatic Asylums.—In reply to Mr. Chiozza Money, Mr. Gladstone stated that the following were the numbers of escapes and recaptures respectively in the last five years from asylums in England and Wales:

1904	367	327
1905	363	328
1906	396	349
1907	356	317
1908	364	308
Total	1,846	1,629

In answer to a further question respecting the 67 imbeciles and lunatics who escaped in the first three months of 1909, as to their classification, as to their degree of mental deficiency, their recapture, and the steps to be taken to prevent such escapes, the Home Secretary said that the Commissioners in Lunacy could not yet furnish him with the information referred to in the first part of the question. Fifty-seven out of the 67 who escaped were recaptured. The Commissioners considered, and he agreed, that asylum authorities generally in the country took proper precaution to prevent escapes. As they stated in the report which was presented to Parliament last week, public opinion would not endorse the retrograde step of making asylums once more in the nature of prisons.

X-ray Research.—A grant out of the Royal Bounty Fund has been made to Mr. H. W. Cox, who recently sustained serious and permanent injuries in connexion with x-ray research work.

Business after Easter.—When the House of Commons meets on April 19th the Indian Councils Bill will be considered in Committee and will probably occupy the whole of the sitting. On Tuesday the second reading of some more or less non-controversial bills will be taken, such as the Houses of Parliament Bill, and Trawling in Prohibited Areas (Prevention) Bill. On Wednesday the Welsh Dis-establishment Bill will be introduced and a full dress debate will take place, and in the evening there will be a motion on the inspection of mines. On Thursday there will be a debate on artesian drainage in Ireland, on the motion to go into Committee on the Civil Service Estimates, and on Friday a private member's bill (Education Administrative Provisions) will come on for second reading.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LEEDS.

MEDICAL INSPECTORS FOR LEEDS SCHOOL CHILDREN.

ON March 13th some account was given in this column of the arrangements come to by the Education Committee of the City Council as to the examination of school children and as to the scale of remuneration of the medical men to be appointed. It will be remembered that the general supervision of school inspection remains in the hands of the medical officer of health, Dr. Spottiswoode Cameron. One half-time school medical officer has been appointed at a salary of £150 per annum. By the term "half-time" presumably is meant the devotion daily of some two and a half to three hours to the work during the school terms. To the position of part-time medical officers nineteen appointments have been made, two of these being filled by ladies. The scale of remuneration, it will be remembered, for these positions is fixed at one guinea for thirty examinations. All the appointments are made to terminate on July 31st, when the scheme will be reconsidered by the Education Committee.

ADMISSION OF WOMEN TO THE LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

The result of the special meeting of this society, which was announced in the JOURNAL of January 2nd as about to be held, was favourable to the recommendation of the committee that it should be specifically stated that women are eligible for admission to the society. The motion was proposed by Dr. Griffith and seconded by Mr. Moynihan, and, though there was some opposition, it was carried by a large majority. At a recent meeting of the society those who are in favour of the admission of women had the satisfaction of taking part in the election by ballot of a lady candidate. It may be mentioned that in the ballot one black ball in five excludes.

BACK-TO-BACK HOUSES IN LEEDS.

There are many people in Leeds who are greatly concerned with the special clause of the Housing and Town Planning Bill, which, if passed, will put an end to the erection of back-to-back houses. There are an enormous number of such houses in Leeds, but it is fair to point out that the local Act which renders the erection of this type of house possible contains some very stringent conditions as to the number of houses in a row or block, the width of the surrounding streets, the space between neighbouring blocks, and the sanitary arrangements. It is felt that the kind of back-to-back house which it is intended by the Act to prohibit is widely different from those which have now for many years been erected in Leeds. Many of these modern houses are in blocks of eight, and when arranged in continuous rows they abut on streets not more than 120 yards in length, and have forecourts of not less than 15 feet deep, while the streets themselves must be not less than 36 feet wide. Each house is provided with separate drains and ventilating pipes, and the accommodation consists of the following: In the basement is a wash cellar, pantry, and coal-place. On the ground floor is the living-room and scullery, with sink, bath, and cupboard. The second floor contains one large bedroom and one small bedroom; while there is a large attic above. Of course, the chief point against the back-to-back house is the absence of through ventilation. The working classes in Leeds have a strong objection to living in tenements, and have a laudable ambition to secure self-contained houses. The kind of house indicated above, with an average frontage of 20 feet, can be obtained at a rental of 5s. 6d. a week, while it is said that a through house, having a frontage of only 14 feet, cannot be erected so as to be let at less than 7s. 6d. a week. On the other hand, one hears these figures authoritatively called in question. An influential deputation from the City Council waited on the President of the Local Government Board to urge the omission or modification of the clause in the bill. The deputation pointed out that the death-rate of Leeds was the lowest of all the large towns, with the

exception of London, and the sanitary and financial arguments were dealt with. Mr. Burns seems to have been adamant and to have presented an absolutely unyielding front. He said the matter had been fully considered by the Committee and that the Government was not disposed to make any distinction between one kind of back-to-back house and another.

MANCHESTER AND DISTRICT.

THE MENTALLY DEFECTIVE UNDER THE POOR LAW.

A NOTEWORTHY letter appeared in the *Manchester Guardian* a short time ago signed by three well-known Manchester medical men and three laymen, drawing special attention to the facts given in the Minority Report of the Poor Law Commission with reference to the treatment of the mentally defective under the Poor Law. The total number of the mentally defectives now residing in the wards of the general mixed workhouses in the kingdom is over 60,000. The Minority Report says:

We have ourselves seen idiots who are physically offensive or mischievous, or so noisy as to create a disturbance by day and by night with their howls, living in the ordinary wards, to the perpetual annoyance and disgust of the other inmates. We have seen half-witted women nursing the sick, feeble-minded women in charge of the babies, and imbecile old men put to look after the boys out of school hours. We have seen expectant mothers, who have come in for their confinements, by day and by night working, eating, and sleeping in close companionship with idiots and imbeciles of revolting habits and hideous appearance.

It would seem that the principal reason for this state of affairs is that the labour of these mental defectives is useful, and in small rural workhouses actually indispensable to their administration on present lines. In workhouse after workhouse the Commission was informed reliance was placed on the imbeciles for practically all the manual work of the establishment; the Local Government Board refused to issue an order to put an end to this apparently because the President had been advised that without the mentally defective women in particular the general mixed workhouses in the rural districts could not be carried on. In face of such facts the letter urges that pressure should be brought to bear on the authorities to order the removal from workhouses of all imbeciles, including epileptics, inebriates, lunatics, and idiots of all ages, that they should be withdrawn from the destitution authorities, and that the entire responsibility for them should be entrusted to the county or county borough councils acting by statutory committees in which the asylums committees should be merged. The letter goes on:

It would be nothing short of a crime if these poor people, whose mental condition and not their poverty or their crime is the real ground of their claim for help from the State, were allowed to continue in their present conditions. . . . Our concern is to get the feeble-minded removed from workhouses and from the taint of pauperism.

The fundamental defect of the medical service under the Poor Law is, it is urged, the fact that prevention of disease is regarded as outside its scope; simple curative treatment is all the guardians, even at their best, aim at, but in the case of the feeble-minded even the veriest rudiments of curative treatment are neglected. Not only are both prevention and cure alike neglected, but it would seem, the writers consider, as if everything were done to foster the contagion of feeble-mindedness, and, altogether apart from the taint of pauperism, justice and humanity demand that the feeble-minded should be removed from the jurisdiction of boards of guardians.

COUNTY OF DURHAM.

SUNDERLAND INFIRMARY.

RECENTLY Mr. T. F. Hoggood retired from the post of honorary surgeon, which he occupied for the last thirty years. He has been appointed a consulting surgeon to the institution with the care of two beds. The committee presented him, as a mark of their esteem, with a large portrait of himself, a duplicate of which is now hanging in the reception-room of the infirmary. Dr. Ayre Smith has been elected an honorary surgeon in Mr. Hoggood's stead.

On the recommendation of the Medical Board it has been decided to appoint on May 13th for one year; as an

experiment, two honorary assistant physicians (one to take charge of the pathological and the other the electrical department) and two honorary assistant surgeons. Many candidates are already in the field, especially for the two last posts. The Children's Hospital (an annexe to the General Infirmary), on the outskirts of the town, is making satisfactory progress, and to it later an honorary physician and an honorary surgeon will be appointed.

TUBERCULOSIS.

A New County Sanatorium for Women.

Lord Barnard, the President of the Society for the Prevention and Cure of Consumption in the County of Durham, will open the New Sanatorium for Women at Wolsingham on May 1st. The institution will provide accommodation for twenty-eight females (above the age of 10 years), and the Stanhope Sanatorium, with its forty-five beds, will be reserved for males only. The latter institution was opened in May, 1900, and over 1,000 patients have been admitted to it; many hundreds have been restored to work, of whom a very large proportion are still at work. For some years the committee has felt, in view of the increasingly large number of applicants for admission, that it is desirable to acquire another building. With this end in view, the Leazes House, Wolsingham, a beautifully situated mansion standing in five acres of charming grounds, together with an adjoining field of ten acres, was purchased on October 16th last, and has been transformed and equipped as a sanatorium, a purpose for which it is admirably adapted. It is estimated that £1,000 will be required in order to defray the cost of the necessary alterations and furnishing. The ladies of the county have gracefully undertaken to provide this sum for their suffering sisters, (and about half the amount has been subscribed already. It is expected that the new sanatorium, like that at Stanhope, will be practically self-supporting by means of patients' contributions, annual grants from local authorities, and workmen's subscriptions.

Invitations to be present at the ceremony have been sent to the medical men of the county, to the various sanitary authorities, boards of guardians, and to representative workmen of the different shipbuilding yards, miners' lodges, etc. The committee has invited the various local authorities to co-operate with it in subscribing £75 a year for more beds in the sanatorium, and thus helping to carry out the recent recommendations of the Local Government Board, and so secure the best results in helping to make consumption as "rare as leprosy." Last year fifteen local authorities sent 66 consumptives for treatment.

Proposed Home for Advanced Cases.

As the advanced cases of the disease are the most dangerous to the community, especially when occurring in houses with insufficient accommodation, the committee is asking the sanitary authorities and boards of guardians of the county to support a movement to provide a home for advanced cases by giving a donation towards providing and equipping such a home by subsidizing beds on similar terms as in the two sanatoriums for early cases. It is to be hoped that this appeal will meet with an adequate response, so that the terrible evils of poverty and misery which follow in the wake of consumption may be diminished and the burden on the rates thereby entailed lessened. During the last ten years the death-rate in the county from consumption has been reduced from near 14 to near 11 per 10,000 persons. The Secretary of the Society is Mr. Fred. Forrest, 54, John Street, Sunderland, and Dr. Menzies of Wolsingham has been appointed medical officer to the new sanatorium.

WALES.

THE EBBW VALE DISPUTE.

In the JOURNAL of March 20th (p. 750) we gave, on the authority of the *Western Mail*, an account of certain negotiations which seemed to open a way to the settlement of the long-standing dispute between the directors of the Ebbw Vale Workmen's Fund and the medical men employed under that fund. According to the *Western Mail* of April 5th, however, the workmen are not satisfied

with the agreement previously accepted by a considerable majority. Our contemporary says:

A further complication has arisen in the Ebbw Vale Workmen's Doctor's Fund dispute. Recently the Victoria section of the payees refused to accept the result of the ballot which was taken to effect a settlement of the disagreement caused by the Cwm section dispute, and on Saturday the Ebbw Vale payees at a mass meeting took a similar attitude. A long and heated discussion took place upon the manner in which the last ballot had been taken, several of the speakers declaring that the issue had been so confused as to make it misleading, and that the result was not binding on either party. Several resolutions and amendments were submitted to the meeting, the one ultimately carried being:

That another ballot, arranged by the workmen themselves, should be taken, and that the plain issue be for or against the reinstatement, and that the conditions be made binding upon all parties.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

St. Mungo's College, Glasgow.

DR. DAVID McKAIL has been appointed by the Governors of St. Mungo's College, Glasgow, Lecturer on Forensic Medicine and Hygiene, in succession to Dr. Hugh Galt.

GLASGOW UNIVERSITY: PRIVAT-DOCENTEN PROPOSAL.

At a meeting of the General Council of the University of Glasgow held recently a report was received from a committee which dealt with the proposal to give a trial to a system of instituting lecturers having a status similar to that of the privat-docenten in the German universities. Dr. Kerr moved that distinguished graduates who make application to the University Court to teach classes in the University qualifying for graduation should, when the University Court is satisfied of their ability and fitness, be appointed Lecturers in the University, and should be granted class-room accommodation, in so far as that is possible. It was intended that the University should not pay these new Lecturers, but give them house room, and allow them to live on the fees they obtained. The motion was duly seconded, and after some discussion it was agreed that the resolution should be sent to the University Court for approval.

ABERDEEN GRADUATION CEREMONY.

As at St. Andrews University, the number of women who take the M.A. degree is increasing; out of 116 who recently graduated M.A. 46 were women.

Natal.

THE COOLIE QUESTION.

At a meeting of the Durban Division of the British Medical Association last November the position of medical men in charge of imported coolies was brought under discussion. Two of these officers were present, and protested that matters of this sort should first be discussed by Indian medical officers themselves, and only by the Division at a later date and at their request. Nevertheless, resolutions were passed authorizing the commencement of an inquiry on the subject. Little effect, however, seems to have been given to them, and the main result was to stimulate the formation or, rather, resuscitation of a body specifically representing the interests of the medical men in question. This was brought about by a circular inviting coolie medical officers to attend a meeting at Durban, and to dine with the medical superintendent officer of the Indentured Labour Immigration Board at its conclusion. Only seven out of a total of some twenty attended, but this was no doubt due to the great distance which many officers would have had to travel. The meeting was a success, and resulted in the establishment of the Indian Medical Officers' Association, with Dr. Bonnar as president. According to a report of the proceedings which has reached us,

The principal business before the meeting was the attitude to be taken by Indian medical officers in giving evidence before the Commission on Indian Immigration now taking evidence in Durban. All those present, with the exception of one member, who complained of inadequate salary, expressed themselves as

satisfied with the terms of their engagement under the board. The board had proved themselves courteous and considerate as employers, and the hope was freely expressed that they might have nothing to do with the Government. The secretary stated that he had received many letters from Indian medical officers unable to attend the meeting, expressing indignation at the statements made that, owing to their control by the board, they were unable to do their duty to indentured Indians. The general feeling of his correspondents was against any change. The treatment of indentured Indians by their employers was also discussed: all those present testified to the fact that, with very few exceptions, employers were humane and considerate. One Indian medical officer present, who has had considerable Indian experience, expressed very strongly the opinion that the condition of Indians in this country was infinitely better in every way than their condition in India. Members felt—and this was freely expressed—that undivided control by the board would be the best solution of present difficulties, and that control by the Protector of Indian Immigrants was impossible. At present certain matters had to be reported to the board, others to the protector or medical officer for the colony; this multiplicity of control makes the work of Indian medical officers very difficult. It was finally decided that Dr. Bonnar, the president of the association, be asked to give evidence, and that the matter be further considered by the committee. It was also decided to inform the Pietermaritzburg and Durban Divisions of the British Medical Association that an Indian medical officers' association had been formed, and to thank them for their interest and help in the past. Certain articles and paragraphs purporting to express current medical news in Natal, and which has appeared lately in the *BRITISH MEDICAL JOURNAL* and in the *South African Medical Record*, were then considered. It was freely stated that the news complained of was inaccurate and misleading, and the secretary was empowered to take such steps as might be necessary in order that the publication of statements injurious to the interests of Indian medical officers might cease.

From this it is clear that a surmise expressed on the last occasion the coolie question found place in these columns was accurate, and that many, if not all, the medical officers would prefer to remain under the Immigration Board. As, however, at least half of them already hold posts under Government as well as under the board, it is clear that they cannot all of them escape having anything to do with Government. We are glad to note that the service, so far as it was represented at this meeting, was able to say that it is courteously and considerately treated, and the opinion expressed that employers, as a rule, are humane to the coolies is also satisfactory so far as it goes. On the other hand, the treatment the topic received is not calculated to end the controversy, for it seems to have been forgotten that the terms on which medical officers in charge of coolies are employed is a matter, not of limited or individual interest, but of wide and general importance. There are at least five parties amply entitled to a say in the matter: (1) The estate owners who import the coolies and pay the salaries of the men engaged to look after them; (2) these medical men themselves; (3) the coolies; (4) the health authorities of the colony; (5) the general public. The difficulties of the health authorities in keeping up and improving the standard of health in the colony are materially influenced by the amount of care exercised in the selection of coolies for importation, and by the fashion in which they are dealt with on the estates; and the same points affect the public. Recently, for instance, it has been seriously alarmed by the revelations made as to the prevalence of ankylostomiasis among imported coolies, and as to its commencing spread among the white inhabitants. Furthermore, it is by permission of the public that coolies are imported, and the public is bound to see that the arrangements made for their care are of a thoroughly satisfactory kind. This is a point on which grave doubts were thrown some eighteen months ago by the Protector of Immigrants, the official charged to represent the public in the matter. As already stated, he recorded an opinion to the effect that the arrangements under which medical officers of the Immigration Board hold office are detrimental to the interests of the coolies. For the rest it may be noted that we are not aware of any instance in which the facts published in our columns have been either inaccurate or misleading, but it may well be that the opinions expressed thereon do not meet the views of some of those affected. This is much to be regretted, but it cannot be overlooked that the point at issue is not whether medical officers at present in the service are contented with their position, but whether the striking pronouncement of the Protector

of Immigrants is well or ill-founded. As at present advised, we share his view that control of medical officers in charge of the coolies should rest not in the hands of estate owners, but of representatives of the public. In other words, these officers should be Government officials and quite independent of the estate owners for whose coolies they are medically responsible.

Correspondence.

HUNGER PAIN AND DUODENAL ULCER.

SIR,—I shall write no more at present on the symptoms ascribed by Mr. Moynihan to duodenal ulcer, as I am quite prepared to be convinced that he is correct on this point, and I look forward to an opportunity of availing myself of his hospitality and seeing some of the brilliant abdominal surgery which has made the Leeds School famous the world over.

But I desire to protest most emphatically against Mr. Moynihan's remarks on the value of *post-mortem* evidence. He writes that he "cannot conceive that the frequency of the fatality of any disease is to be measured by the number of bodies in which evidence of it is detected in the *post-mortem* room." But why not? If a man dies as a result of a duodenal ulcer, the duodenal ulcer will surely be found at the *post-mortem* examination. Or does Mr. Moynihan believe that the bodies of people with duodenal ulcer, who have not received surgical salvation, go straight to another world without passing through the *post-mortem* room?

Mr. Moynihan repeats that nothing but surgical treatment can cure a patient with a duodenal ulcer. The ulcer must therefore still be present *post-mortem*, if no operation has been performed, whatever may have been the cause of death. Mr. Moynihan admits that "an attack" of the symptoms which he ascribes to duodenal ulcer can be easily relieved by medical treatment; the extreme frequency of these symptoms—if they are really always due to a duodenal ulcer—compared with the rarity of an unhealed duodenal ulcer in the *post-mortem* room shows that the relief by medical treatment is indeed a cure.

"But what of recurrence?" Mr. Moynihan asks, in speaking of the results of medical treatment. "And what of recurrence?" I ask, in reference to the results of surgical treatment. In the last fortnight I have seen three patients, who have, apparently as a last resource, come to a physician for the recurrence of symptoms, which temporarily disappeared after operations undertaken for the relief of supposed gall stones or gastric ulcer. Two of these patients had had two abdominal operations; one had had three; but there comes a time when even the greatest lover of operations wearies of them and ceases to return to the surgeon, who is no more justified in assuming that he has cured his patient than is the physician, who is satisfied with improvement, which has lasted during the comparatively short period he can keep a hospital outpatient under observation.

Mr. Moynihan wonders whether the expression "unjustifiable," applied by me in my last letter to the vast majority of operations performed on patients suffering from symptoms ascribed to duodenal ulcer, was weighed. It was. And after reading his second letter I cannot see the smallest reason for withdrawing it.—I am, etc.

London, W., April 13th.

ARTHUR F. HERTZ.

SIR,—It seems to me that there is some fear that in the multitude of side issues raised the real point, the causation of what is called hunger pain, may be overlooked.

The cause cannot be simply the presence of excess of hydrochloric acid. Acid of much greater strength and in much larger quantity than is ever secreted by the stomach may be swallowed without causing the least pain; and, as Lennander has shown, the walls of the stomach and of the bowel may be cauterized with acid without the patient even being aware of it; nor so far as this is concerned, does it make any difference whether there is an ulcer present or not. It is certain now that the pain of gastric ulcer is not due to the acid contents of the stomach irritating sensory nerves on the floor of the ulcer, for there

are no sensory nerves there, and the same thing is true of duodenal ulcer.

The real cause of hunger pain is cramp or spasm of the unstripped muscular fibre in the wall of the pylorus. The character of the pain, the time of its occurrence, and, above all, the peculiar means by which it is relieved, all point to this; and the severity of the pain which is caused by irregular or excessive contraction of unstripped muscular fibre in other organs, where ordinary sensory nerves are equally deficient, needs no mention.

Hunger pain may occur simply from the work being too great, from overstrain or overexertion in a patient whose muscular system (so far as the digestive tract is concerned) is unduly weak. There is a want of proportion between the work to be done and the force there is to do it; and whenever this happens in connexion with unstripped muscular fibre, pain results. It occurs more readily when the walls of the stomach and duodenum have been rendered over-sensitive by some disorder of digestion—a disorder in which, perhaps, an excess of hydrochloric acid is present.

"Hyperchlorhydria" is an unhappy term—one to be avoided. Whatever may be the facts in connexion with it, it is a mistake to designate what we, in our present state of ignorance, call a functional disorder by the name of a symptom which may not always be present.

But this pain is much more likely to occur, and is much more severe when it does occur, if the wall of the bowel has been made exquisitely sensitive by the action of some continuous irritation or slight degree of inflammation, such as is always present when there is an ulcer. Whenever there is an ulcer, either in the stomach or the duodenum, the contact of any foreign substance, acid or not, with the surface of the sore irritates it; and the irritation, persisting for hours together, spreads to all the tissues around, rendering them hyperæmic and making them infinitely more sensitive to every kind of stimulus.

It is not the occurrence of hunger pain that is diagnostic of duodenal ulcer, but its recurrence, its persistence, and its severity. When it comes back again and again in spite of all that is done to relieve it, and when it obstinately persists in the face of ordinary treatment, there can be little doubt that it is not the outcome of a mere functional disorder, but of some definite pathological lesion.—I am, etc.,

London, W., April 10th.

C. MANSELL MOUTRIE.

SIR,—My excuse for intruding on the present discussion of duodenal ulcer is based upon *personal* experience of (1) "indigestion" since boyhood; (2) duodenal ulcer for about ten years; (3) perforation of a duodenal ulcer, laparotomy; (4) duodenal stenosis; (5) gastro-enterostomy. A history of this kind ought to throw some light on one or two of the points at present in dispute.

To my mind the question of what is and what is not pain is a most important one here, and one which is exceedingly difficult of solution. Looking back on my own symptoms, it was only when the pain became very aggravated indeed that I was induced to admit that I did suffer. The question, "Do you ever have pain after food?" almost invariably in my experience calls forth such a reply as, "No, I have no pain, but I have always suffered from indigestion." When you come to close quarters you will often find that such a person has now and then been kept awake at night, and has had to take this or that homely remedy for "indigestion."

Leaving the subject of pain, there are in addition two main difficulties in the way of diagnosis. In the first place, we must decide whether or not the trouble is of peptic origin. That this is a real difficulty I have had proved in my own case, for amongst the various opinions of my ailments I have had: chronic constipation (by a senior physician to one of the largest of the London hospitals); neurasthenia (within six days of perforation, by a well-known physician); cholelithiasis, etc. However, into that side of the picture I do not intend to enter, for it is not the one under consideration at present. The discussion, as I understand it, aims at deciding what are the symptoms of duodenal ulcer, and whether such symptoms are pathognomonic. In discussing this question we must ask another, namely, Is there such a thing as a pre-ulcerative stage? And if so, is it possible to distinguish it by its symptoms from the fully-developed ulcer?

Judging by my own experience, I cannot remember when I began to suffer from "indigestion," but I should not have thought of describing the discomfort as "pain." Even looking back on it in the light of experience, it could not be described as pain. At worst it was discomfort, more or less severe, accompanied by fullness, pyrosis, and eructations of gas. In short, it was what is usually termed "heartburn." It always diminished as the stomach emptied itself, and I learnt by experience that some form of fairly violent athletic exercise was most effective for this purpose, and I am inclined to think that the appetite for the next meal was a trifle excessive. In short, these are the symptoms of "hyperchlorhydria," or "acid dyspepsia." This is the "preulcerative" stage of duodenal ulcer.

The second or "ulcerative" stage has very definite symptoms indeed. As exemplified in my own case they might have been written down in the *Practitioner* by Mr. Moynihan at my dictation, so accurately has he described them. Of the pain (though I did not at first call it pain) there is no doubt: it came on two to four hours after a meal, frequently during the night; was relieved by the next meal or by alkalis. The first attack of hunger pain lasted only a fortnight, when it gave place to the "usual indigestion." After a time it became practically constant, until just before perforation it lasted from about one hour after food till relieved by the next meal. It gave most trouble during the night, more than once preventing any sleep whatsoever. What I wish specially to point out is that the subjective sensations of this stage are as different from those of the preliminary stage as the pain of perforation is from either. And judging by symptoms *alone* one feels justified in concluding that there are two stages, the first or preulcerative, characterized by fullness and discomfort after meals, accompanied by pyrosis, but passing away as the stomach gets empty; the second or ulcerative stage, characterized by the "hunger pain," which is more severe, lasts longer, gets worse towards the end of digestion, and is especially apt to be troublesome at night. The symptoms of these two stages agree in the time at which the discomfort begins, and in the fact that both are relieved by the taking of alkalis, or alkaline food such as milk and soda. They disagree in the character of the pain. They disagree in the effect of ordinary emptying of the stomach via the pylorus, which lessens preulcerative but increases hunger pain. Preulcerative pain does not occur at night, whilst the pain of ulcer is then most troublesome. The two conditions are not, however, separate entities, but stages in a morbid process. They can be recognized and differentiated.

From my own experience, personal as well as professional, I should say there is ample room for both Dr. Hutchison's cases of acid dyspepsia, and for Mr. Moynihan's cases of duodenal ulcer, but there is a danger of Dr. Hutchison failing to recognize duodenal ulcer, as there is of Mr. Moynihan failing to recognize hyperchlorhydria. Of the two I should prefer to be one of Mr. Moynihan's mistakes.—I am, etc.,

Belfast, April 6th.

S. T. IRWIN, M.B., M.Ch.

THE MEDICAL PROFESSION AND LIFE ASSURANCE.

SIR,—Mr. Snodgrass's remarks in the *BRITISH MEDICAL JOURNAL* of April 10th about Dr. Farrar's address on this subject seem to me to show that Mr. Snodgrass is needlessly anxious to vindicate the attitude of life assurance companies in matters relating to the payment of fees to doctors by the companies. I fail to see on what grounds apology need be offered or explanation given on behalf of the procedure of those companies in this connexion. A part of the business of the companies is to buy in the cheapest market the services of the medical men they believe are equal to doing well the medical part of the business of life assurance. If the medical men do not think the fees paid by the offices are sufficient remuneration for the work done the remedy is very simple—decline to do the work. The companies must have medical guidance in the selection and classifying of proposers for life assurance; but so long as the companies believe they can get certain medical work well enough done for half-guinea fees they will not pay more than 10s. 6d. for that work. If they paid more their shareholders would have just cause of complaint. If

anyone is to be blamed because these half-guinea fees are to-day in common use, it is the doctors, not the companies, who are blameworthy.

To me it seems irrelevant and a sign of weakness to speak of "sweating" the medical advisers of assurance companies. These men are members of a great profession which, if it cannot take care of its own interests, is, I think, undeserving of either sympathy or consideration from those who profit by its services. So long as medical men tumble over one another, as they now do, in a struggle to secure for themselves poorly paid, and even unpaid, appointments, the poor pay and the no pay will, as a matter of course, remain just as they are. There is much that sorely needs mending in the business aspects of the work done by the medical profession in connexion with both public and private appointments, and in the latter I include such work as is done by the medical advisers of insurance companies. In forty years' personal experience of both public and private appointments I have, from year to year, heard and read of the same sorts of complaints by medical men. To-day we are, in my opinion, in such matters exactly where we were in the late Sixties of last century.

The remedy for all this is plainly to be seen by even the unobservant in our ranks. Were we united in one great organization what we could not then do for ourselves would be unattainable. Until we are in that sense a united profession we do but waste time and cause amusement to those who profit by the present state of our affairs by bemoaning our fate in the medical journals or any other section of the press.—I am, etc.,

London, W., April 12th.

G. A. HERON.

SIR,—The medical profession *cannot afford* to do the work of examination and report for insurance companies. The pay is absolutely inadequate, and to me has entailed heavy loss in fifty-one years.

If a life is rejected or extra premium demanded, the proposer and his friends put it down to the medical examiner, and resent it, and despitely use him.

The remedy. Let the companies raise their premiums, and take lives without medical report, for which they cannot or will not pay, or have a whole-time man. Good lives do not want a report; the shaly lives the profession cannot afford to report on at present payment.—I am, etc.,

Framlingham, April 12th.

GEO. E. JEAFFRESON.

SIR,—There is one paragraph at least in the letter of Mr. Snodgrass upon this subject, published in the JOURNAL of April 10th, p. 930, which should not be allowed to pass without comment, since it bears upon the face of it the strongest refutation possible of the very thesis Mr. Snodgrass wishes to propound. He says:

"Dr. Farrar suggests that very frequently large sums are lost to the companies through early industrial claims which would otherwise be prevented by the expenditure of a guinea on medical examination. How much greater, and how much more certain, would the loss to the companies be if an expense of this kind were to be incurred in connexion with those cases! As a matter of fact, the companies would all prefer to have a medical examination in every case, but the cost, as has just been shown, is prohibitive."

Surely Mr. Snodgrass must appreciate the fact that the expenditure of a guinea upon a *thorough* medical examination (even where the policy is only for so small a sum as £25) must be the wisest course, since if, on the one hand, it brings to light the fact that through some defect (for example, Bright's disease, phthisis, cardiac disease, sarcoma, etc.) the proposer's is an unacceptable life, the company is thereby saved the probability of having to pay nearly the whole of the £25 in the course of a year or two, which they would probably be called upon to do if such a life were accepted *without* any medical examination; whereas, on the other hand, if the proposer proves to be a first-class life, the company can well afford a guinea fee on the probability that they would not be called upon to pay the £25 until, at the earliest, the usual span of life had run. Hence the words, "how much greater and how much more certain" become of no effect, and the "cost" is not "prohibitive." Of course, if Mr. Snodgrass is so short-sighted as only to look "ten or fifteen weeks" ahead in the case of a first-class life it is easy to understand his

attitude, but in calculating the company's receipts he ought to look ahead to the usual span of such a life. And let not Mr. Snodgrass bring against me the well-worn accusation of quoting apart from the context, because his attitude has been considered from every contextual aspect.

I should like to point out clearly to Mr. Snodgrass that, if a given thorough fully detailed examination and report upon a life is at any time or in any instance worth a guinea fee, the amount of the insurance does not in any way affect such an examination and report, and it is a matter of indifference to the examiner what sum is at stake, since all he has to take cognizance of is the fact that an opinion upon a given life is required of him after he has made a thorough examination. Therefore, whenever a fully detailed examination and report is required the fee remains the same, quite irrespective of the sum to be assured, and surely Mr. Snodgrass would not suggest that the examiner should make the company a present of half the fee in order that their profits might be the larger, which is what the tenor of his argument entails.—I am, etc.,

Lichfield, April 12th.

F. M. ROWLAND, M.D.

KISSING THE BOOK.

SIR,—I was very glad to see your sensible little leaderette anent the dirty, dangerous, and unnecessary habit of kissing the book—dirty, because it can hardly be a pleasant thing for a clean and refined man or woman to imprint a chaste salute on a volume which has just been pressed by the literally foul-mouthed lips of some beer-drinking, tobacco-smoking, filthy ruffian; dangerous, because ethereal disease has undoubtedly been caught by direct contagion in this way; and unnecessary, because it is surely an insult to a truthful, law-abiding citizen to tell him that he cannot be believed except on his oath. If one has a natural taste for perjury, I hardly think he will be restrained from strictly economizing the truth by hearing some words rapidly gabbled over to him by an official, and I should like to sweep the whole stupid process literally out of court, bag and baggage.

I have had the great privilege of swearing myself six times into the House of Commons, and can never forget the indecent scene. Recently-elected members stood three and four deep round the table struggling for a corner of the book with the energy of a football scrimmage or a pack of hounds squabbling round their dinner trough for the best bones. Bradlaugh did a real service when he declined to take part in such a meaningless ceremony, which had as little binding effect upon him as on the other occupants of the green benches, none of whom, I guarantee, has the slightest notion what he is swearing about. Surely, if a man is fit to be a member of Parliament, he is fit to make and administer laws without being officially bound over to work within the limits of certain theological precepts. But as long as the law exists it must be obeyed, and it is well that people should know—and I am not sure that all judges are aware of the fact—that any one can claim the right to be sworn Scottish fashion.—I am, etc.,

Hyères (Var), April 6th.

R. FARQUHARSON.

THE TREATMENT OF CHILDREN.

SIR,—The report of the Education Committee of the London County Council on the medical treatment of school children has very rapidly confirmed the warning contained in my letter published in the JOURNAL of March 27th, page 817. This committee consider that under certain circumstances it is desirable to utilize existing institutions for the medical treatment of children, and that financial help should be given such institutions in return for special facilities. I have no doubt that this recommendation is the first of a series that will shortly appear from various education committees all over the country, and unless something is done at once the profession will certainly be caught napping. A general and vague consideration of the principle involved will not advance the position at all unless such discussions are at once followed by a practical and business-like consideration of the matter by joint meetings of men in practice and selected members of the local hospital staffs.

The influence of the profession and of the British Medical Association might well be directed towards

support of the suggestion that education committees should be given power to recover the cost of medical treatment of school children from the parents except in cases where it is shown that the parents are not in a position to pay, but I would urge the importance of observing the principle that it is not the business of the profession to direct public authorities how to carry out their legal obligations. Their part is merely to take up the position that all medical work performed for public authorities must be adequately remunerated. It would be well for us to stop here and to refrain from pointing out the possible and probable effects of subsidies to hospitals. Whether such would lead to municipalization or nationalization is not our concern so long as we maintain a sufficiently united front to secure to the profession adequate remuneration for all services rendered. In fact, it appears to me that the only solution of the difficulty was contained in my previous letter, which suggested that possibly the time had arrived for the medical profession to dissociate itself entirely from the principle of giving services to institutions as charity in any circumstances.—I am, etc.,

Winchester, April 6th.

R. A. LYSTER.

RATIONAL DRESS FOR THE SOLDIER.

SIR,—With reference to the letter on the above subject by Lieutenant-Colonel C. J. McCartie in the *JOURNAL* of April 3rd, may I be permitted to recall the fact that after the publication of my essay on Diseases of the Heart amongst Soldiers, in 1870,¹ in which I attributed this disease largely to tight clothing and accoutrements, permission was granted to me at the Horse Guards to have a tunic made at the Royal Army Clothing Factory after my own design. The main point of it was to remove all constriction round the neck by not allowing any fastening by hook or button above the chest wall.

A soldier dressed in such tunic was inspected by H.R.H. the Duke of Cambridge, then Commander-in-Chief, at the Horse Guards, and I was informed, approved of by him; but I heard nothing more of it for some time, when I was told, unofficially, by an official that it could not then be adopted owing to the thousands of collars already cut out, and to the fact that it would cost one halfpenny more per tunic!

I hope that, like others before me, I did some little good in dealing with the subject of tight clothing; but it seems curious that, after nearly forty years, attention has still to be drawn to the same subject.—I am, etc.,

A. B. R. MYERS,

London, S.W., April 6th. Brigade-Surgeon-Lieutenant-Colonel.

PLEURAL PAINS AND ADHESIONS.

SIR,—I read with much interest the article by Dr. MacLachlan in the *BRITISH MEDICAL JOURNAL* of March 6th, p. 597, in which he draws attention to the importance of pleural pains and their connexion with pleural adhesions, but I feel that he has hardly brought into sufficient prominence the fact that pleural pain not only indicates recent disease of the pleura, but in a large proportion of cases is due to pleural thickening and adhesions of long standing. Certainly, among the patients in sanatoriums, pleural pain is very common, and is met with in those who have a good deal of scar tissue due to healed or healing disease, perhaps more frequently than when pleural involvement is recent. Indeed, all patients with satisfactorily-healed tuberculous lesions in which there has been pleural involvement, are liable to attacks of pleural pain for years after a satisfactory cure has been effected.

What the exact pathological change in fibrous tissue may be which causes the pain is doubtful, but it is a peculiarity of all fibrous tissue of pathological origin; old adhesions in joints after injury or disease, old scars, corns, etc., are all liable to cause pain at times, and more especially, it would appear, during drops in barometric pressure. It is this peculiarity which is largely responsible for the idea that damp is bad for rheumatism. The character of the pain suggests neuritis, for in addition to the "dull aching pain" there are frequently sharp twinges, which radiate down the course of a nerve; moreover, there is nearly always some superficial tenderness over some point along the

course of the nerve. It is largely on account of this tenderness that the condition is so often looked on as muscular rheumatism or pleurodynia and the important condition inside the chest wall is overlooked. A very considerable number of persons, who later develop more definite signs of phthisis pulmonalis, give a history of having been treated some time previously for "rheumatism of the chest." It is probable that these pains were the early signals of the disease; a warning which may not be accompanied or preceded by cough, although patches of subacute pleuritis are frequently due to involvement of the pleura by extension of a small lesion near the surface of the lung.

Dr. MacLachlan seems to think that 1 out of every 4 or 6 cases of pleurisy is too high a proportion to be tuberculous. Some authorities have found that over 80 per cent. of cases of pleuritis are of tuberculous origin. It is probable that of "chronic" or "subacute" cases the percentage would be even higher than this.

It must be remembered that there is good reason to believe that the majority of persons, whose lungs have at some time been infected by tubercle, recover without the disease ever developing far enough to be recognized.

Besides the positions indicated by Dr. MacLachlan, a common complaint of phthisical patients is an aching in the supraspinous fossa, with pain radiating over the shoulder, down the inner side of the arm and up the neck to the occiput. This is associated, as a rule, with tenderness, and is frequently thought to be rheumatism of the trapezius muscle, but is generally found in those with a lesion, perhaps quite an old one, in the apex of the lung on that side. Some neuralgic pains down the arm may be due to involvement of those branches of the brachial plexus which come into intimate relation with the extreme apex of the lung, but are more frequently due to pressure caused by associated glandular enlargement.

In other parts the tenderness and pain are usually found at the positions at which the branches of the intercostal nerves pierce the deeper structures to become superficial. These positions are not, of course, necessarily the site of the pleural lesion, for the source of irritation may be anywhere along the course of the deep branch of the intercostal nerve.

I cannot agree that opium is necessary in the treatment of this condition. The large majority of cases are readily relieved by painting a large area with a mixture of liniment and tincture of iodine, and by giving 10 grains of aspirin internally thrice daily. When the pain is so severe as to cause considerable dyspnoea, pressure by the hand may be found to give instantaneous relief. In these cases it is better to strap the side at once.

There is one point with regard to the physical signs that is well to remember. Deficiency of breath sounds—a sign almost constantly found—is very largely due to the reflex arrangement by which a whole lobe, or a portion of it, can be put out of gear for a time in order to relieve pain or to give rest to a diseased portion.—I am, etc.,

Mundesley, Norfolk.

ARTHUR DE W. SNOWDEN, M.D.

RURAL NURSING ASSOCIATIONS.

SIR,—Attention has been drawn to the *BRITISH MEDICAL JOURNAL* of the 3rd inst., in which the suggested rules of the Institute for Village Nurses are printed.

The statement that these rules have been altered recently in consequence of representations by the medical profession is quite erroneous. Rule 9 referred to is merely an amplification of the former rule, and embodies the principles on which the Institute has acted from the beginning. The Institute invariably gives the fullest consideration to any authoritative statement of the views of the medical profession, but in the present instance these views cannot be said to have brought about any change in the policy of the Institute, as no change has been made.—I am, etc.,

London, S.W., April 8th.

A. MARTIN LEAKE,

Secretary, Queen Victoria's Jubilee Institute for Nurses.

THE INFLAMMABILITY OF FLANNELETTE.

SIR,—It has come to my knowledge that statements have been widely circulated which would seem to convey the impression that the flame-proof make of flannelette,

¹ On the Etiology and Prevalence of Diseases of the Heart amongst Soldiers. The "Alexander" Prize Essay. London: John Churchill and Sons.

called "Nonflam" and which bears my name, loses its property of resisting fire after washing, and is then as dangerous a material as ordinary flannelette. That this is not the case may be easily proved by any one who will purchase the material, or a garment made of the material, at any of the ordinary shops, and subject it to washings with hot soap and water in the usual manner.

It will be found that even after thirty or more washings the material still retains in a remarkable measure its reluctance to ignite, and that even when it is made to burn it burns with extreme slowness, and the flame goes out on the merest shaking. That such material is absolutely safe to wear—as much so as wool—is shown by the fact that, although millions of yards have been sold during the last five years, no accident has occurred to anyone wearing it: while during the same period an appalling number of burning fatalities have resulted from the wearing of ordinary flannelette.

The misunderstanding in connexion with the safe properties of Nonflam has been traced to the fact that many imitations are in the market, and the public buys these under the impression that it is buying Nonflam. There are short-nap flannelettes filled with soluble salts, and show some resistance to fire before washing, but as soon as these salts have been washed out the material burns with the same readiness and is as dangerous as ordinary flannelette.

It is important, therefore, that those who wish to purchase and test the material shall insist on being supplied with Nonflam, and not a substitute.

In order that this important point as to the permanent flame-resisting properties of Nonflam may be completely and clearly demonstrated, it is proposed to ask several gentlemen who have no interest in the trade to make exhaustive tests, and the results of these will be published from time to time.—I am, etc.,

Victoria University, Manchester, April 8th.

W. H. PERKINS.

*. We have made a comparison of the inflammability of ordinary and Nonflam flannelette. It was found that with ordinary flannelette once washed the slightest momentary contact with flame sufficed to set it on fire, and it burnt away with great rapidity. Another portion was washed with hot water and soap eleven times more, and tested at intervals; there was a very slight diminution of inflammability. In the case of Nonflam, once washed, moderately prolonged contact with flame did not set it on fire; if held in the flame for a considerable time, it smouldered away slowly, and on removal it continued to do so, but did not burn with a flame. It was then washed with hot water and soap and dried; when placed in a flame it behaved as before, but on keeping it in contact for some time and then removing it, it burnt with a flame, but very slowly, and it was easily extinguished. It was then further washed in the same way ten times, and tested at intervals; there was only the slightest variation in its behaviour. After the twelve washings it still required prolonged contact with the flame to cause it to take fire. When it burnt with a flame, but slowly; it left an ash similar in quantity to that given after only once washing, showing that the protecting chemicals were not washed out. It may be taken that it would be but little affected by still further washing. If the flannelette had had the amount of wear that would ordinarily correspond to twelve washings, the amount of the woolly "nap" would probably have been much reduced, and even ordinary flannelette would then be less dangerous. So that a flannelette which is safe after twelve washings may no doubt be regarded as quite satisfactory.

The Services.

ROYAL NAVY MEDICAL SERVICE. DISTRIBUTION OF PRIZES.

THE course of instruction of the newly entered surgeons at Haslar was brought to a close on March 30th by the distribution of prizes by the Commander-in-Chief at Portsmouth, Admiral Sir A. D. Fanshawe, K.C.B.

The gold medal was gained by Surgeon W. A. H. McKerrrow, of Aberdeen University. The microscope was awarded to Surgeon F. G. Hitch, of the London Hospital. The silver medal

and books were awarded to Surgeon J. Glaister, of Glasgow University.

The following list shows the places gained by the combined marks of the London and Haslar examinations:

	Marks.
1. Surgeon W. A. H. McKerrrow, M.B.	5,413
2. Surgeon F. G. Hitch	5,245
3. Surgeon J. Glaister, M.B.	4,765
4. Surgeon T. R. Lloyd-Jones	4,529
5. Surgeon F. G. Hitch, M.B.	4,575
6. Surgeon C. F. Bainbridge, M.B.	4,497
7. Surgeon A. V. J. Richardson, M.B.	4,428
8. Surgeon F. W. Quirk	3,838
9. Surgeon S. L. McLean, M.B.	3,381
10. Surgeon G. R. McGowan	3,880
11. Surgeon B. J. H. Garstin	3,745
12. Surgeon W. Meares, M.B.	3,384
13. Surgeon N. Barclay, M.B.	3,502
14. Surgeon A. C. Wilson	Absent.

THE ARMY MEDICAL CORPS (TERRITORIAL).

EXAMINATIONS FOR PROMOTION.

MAJOR.—The subjects for the examination of majors in the R.A.M.C. (Territorial Force) before promotion to the rank of lieutenant-colonel are enumerated on page 175 of the Regulations for the Territorial Force; they do not prescribe an examination in military law. The following books are recommended: *Regulations for the R.A.M.C., Standing Orders for the R.A.M.C., Training R.A.M.C., and Caldwell's Hygiene*. In Army Order 197 of 1908 it is stated that the "medical history" for the year 1909 is that of the Asiatic campaign (book recommended: A.M.D. report for 1873, pp. 206-259); and the "army medical service" that of the French army (book recommended: *Handbook of the Medical Organization of the French Army*, by Lieutenant-Colonel W. G. Macpherson, C.M.G., R.A.M.C.). There is a recognized school of instruction in each division of the Territorial Force, particulars of which can be obtained from the administrative medical officer of the division.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

THE DUTY OF A SUBSTITUTE.

A. is in attendance upon a patient whose condition he considers serious, but not hopeless; the patient has a relapse and A. is asked, for, but being out B., a neighbouring practitioner, is asked by the relatives to attend. B. considers the case hopeless, and the patient dies on the following morning. The relatives, who expressed general dissatisfaction with A., asked him to give a death certificate, but he referred them to B. A. has heard nothing from B.

*. It would seem that B.'s language should have been more guarded, and he ought to have left a note for A. The action of the friends in dismissing A. terminated his duty towards the patient; but if B. had not seen the case again A. might have given the death certificate, as the friends on reflection would probably admit that they had treated him unjustly and discourteously.

Contract Practice.

ATTENDANCE WITHOUT MEDICINE.

H. L. E. has been approached by the Mutual Property Investment and Accident Company to accept the post of medical officer to its members. The proposed payment is 3s. 6d. a member per annum without medicine, so that the members are apparently required to pay for their medicine extra. He asks whether a medical practitioner would be acting professionally in accepting such an appointment.

*. Although the payment proposed without the obligation of supplying medicine might prove to be more remunerative than the majority of ordinary club payments, it is inadequate for the services required. It has been more than once suggested in the past that the contract of club doctors should not include the supply of medicines, and that club members should pay a small additional sum for every bottle of medicine supplied to them, but we are not aware that it has before been proposed to put the plan into practice, and it will be interesting to see how the experiment succeeds. Such a system would be an improvement on the present.

Obituary.

CLAUDIUS GALEN WHEELHOUSE, F.R.C.S.,

HON. LL.D. MCGILL, HON. D.S. LEEDS,

CONSULTING SURGEON TO THE LEEDS GENERAL INFIRMARY;
EX-PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

Mr. C. G. WHEELHOUSE, so well known for many years as Surgeon to the Leeds General Infirmary, as a devoted friend of the British Medical Association, and as Direct Representative of the profession on the General Medical Council, died on Good Friday at the home which he had made for his old age on the cliff at Filey, overlooking the North Sea and within the bounds of the county which he knew and loved so well.

Claudius Galen Wheelhouse was the second son of Mr. James Wheelhouse, surgeon, of Snaith, in Yorkshire, where he was born on December 29th, 1826. He was sent first to the Grammar School at Snaith, but at the age

of 7 entered at Christ's Hospital, spending three years at the Preparatory School in Hertford, and six years in London. When 16 years of age he was apprenticed to Mr. Ward, of Ollerton, Nottinghamshire, and the advantages he there enjoyed made him in after-years regret the abolition of the apprenticeship system. In his address as President of the British Medical Association at the annual meeting at Leeds in 1889 he discussed the subject at some length, and suggested a modified scheme in which the great field afforded by the county hospitals, work-house infirmaries, and public dispensaries might be utilized. "In pupillage in one or other of these in my humble judgment," he said, "a year, or even two, at the commencement of professional study would prove the very best beginning; and in following the practice to be there seen under the direct guidance and supervision of those who administer them, a youth would see work which in after-life would be of incalculable value to him, and would obtain opportunities for a groundwork which, under the present method of education, are wholly thrown away."

Young Wheelhouse entered the Leeds School of Medicine at the beginning of the winter session of 1846; he became M.R.C.S. in 1849, and L.S.A. in 1850. Shortly afterwards he acted as surgeon to Lord Lincoln, afterwards Duke of Newcastle, and Minister of War, who with a large party made a prolonged yachting cruise to Spain, Greece, Turkey, Egypt, Syria, and Palestine. Mr. Wheelhouse brought home with him a very fine collection of photographs which he had taken by the wax-paper process, the most difficult but the most excellent method which had been devised in the then infant art of photography; the exposures required were long, and the process of development tedious, but the results have hardly been surpassed by any modern process, and Mr. Wheelhouse would occasionally display his treasures to sympathetic friends.

On returning to England in 1851 he settled down at Leeds in partnership with Mr. Garlick, one of the leading practitioners in the town. In the same year he was

Photography by

Mr. C. G. WHEELHOUSE.

Chancellor, Dublin.

on that occasion to the Chancellor, said of Mr. Wheelhouse: "Himself one of the earliest at the Leeds School of Medicine, he was afterwards and for many years one of its most brilliant teachers; possessed of wide sympathies, he was for forty years a member of the staff of the General Infirmary, and an accomplished surgeon who acquired fame far beyond the limits of his native country."

In March, 1864, he was elected at the same time as Mr. T. Pridgin Teale and the late Mr. Nunneley, Surgeon to the Leeds Infirmary. In the same year he became a Fellow by examination of the Royal College of Surgeons of England, and the next twenty years was for him a period of great surgical activity. As an operator he was careful, exact, and thorough, qualities which indeed he displayed in all relations of life. It was the day of conservative surgery when the ideals which had produced the brilliant surgeons of the past who gloried in the speed of their operations were giving way to others having regard to the preservation of parts which under the older system would have been removed. In this new movement Wheelhouse was one of the leaders, but he could be daring on occasion, as is shown by his having performed paracentesis pericardii in 1866. He wrote also on median laparotomy, on perineal section, on the surgery of the epiphyses, and contributed to this JOURNAL in 1885 valuable clinical lectures on pent-up secretions, in which he discussed, among other subjects, the propriety of operating upon abscess of the lung, and on recent advances in abdominal surgery, in which he touched upon operations for gall stones.

Mr. Wheelhouse continued in partnership with Mr. Garlick until that gentleman's death in 1870, and though he did not thereafter give up family practice, his reputation as a surgeon caused his opinion frequently to be sought in consultation throughout the West Riding. It thus came about that during many years he lived a strenuous life, for to his many professional engagements in and around Leeds he added much public work for the profession, to which reference will now be made, although

it would be impossible even to enumerate all the directions in which his active interest in every movement for the advancement of medical knowledge and the maintenance of a high standard of professional honour and efficiency found opportunities.

We may take first his work for the British Medical Association, which he joined in 1859, at a time when its membership was small, and its financial position unstable. Although the membership continued to grow, the finances did not improve to a corresponding degree, and when Mr. Wheelhouse joined the Committee of Council in 1869 it was face to face with a very serious state of things. After debates extending over several years, in which Mr. Wheelhouse took an active share, it was resolved to remove the offices to London, and to replace the office of secretary, which had been held by a medical man, by that of general manager, who should be a man of business training and devote the whole of his time to the work. To this office the late Mr.

Francis Fowke was appointed in 1872, and when in 1881 Mr. Wheelhouse was elected President of the Council he found a very greatly improved state of affairs, to bring about which his own loyal work had in no small degree contributed. Before this, however, he had held the office of Vice-President of the Section of Surgery at the Annual Meeting at Sheffield in 1876, and two years later gave at the Annual Meeting at Bath the Address in Surgery, in which he passed in review the progress then recently made in the practice of surgery, dwelling particularly upon the surgery of the thorax, the abdomen, and pelvis, and upon the reunion and restoration of divided nerves; he took the opportunity also of paying a warm tribute to the great boon conferred on surgery by Lister. "The question," he said, "has recently been asked whether in adopting this principle of antiseptic surgery we 'may not possibly be encouraging a great delusion?' As a practical surgeon," he went on, "I emphatically answer, 'No! it is not a delusion, but a truth of the greatest value'; and in my mind I call up many cases in which, except or such 'delusion,' my patients would have lost their limbs, and oftentimes their lives also."

In 1889, when the fifty-seventh annual meeting of the British Medical Association was held in Leeds, Mr. Wheelhouse was unanimously designated President, although he himself, with characteristic self-effacement, had suggested the name of one of his colleagues, as is more fully related below by Sir Clifford Allbutt. The success of that meeting, which is still remembered by all those who had the privilege of taking part in it, was in no small measure due not only to the cordial welcome and genial hospitality of the President, but to his great executive ability in the ordering of the preliminary arrangements. Mr. Wheelhouse was always a good friend to this JOURNAL, and, fully recognizing the great qualities of the late editor, Mr. Ernest Hart, steadily supported every proposal for its improvement as a medical periodical. He was an occasional contributor to our columns, and we shall not now

be violating any confidence by saying that he was the "Old Member" who contributed to the Queen's Commemoration Number, published on June 19th, 1897, the short history of the British Medical Association from its institution to that time.

Mr. Wheelhouse's great services to the Association and to the profession at large as one of the first Direct Representatives on the General Medical Council were recognized in 1897 when the gold medal of the Association was presented to him. In acknowledging this honour Mr. Wheelhouse said that it had been his great pleasure to serve the Association under varying circumstances for upwards of forty years; through various administrations, through a great variety of circumstances, through poverty and impecuniosity up to wealth, he had been actively engaged in serving the Association, and whatever he had done for it had been done with all his heart and all his soul, for he looked to the advancement of the Association as being the first means of advancing the profession.

When in 1836 the Medical Act of that year brought into existence direct representatives of the profession on the General Medical Council Mr. Wheelhouse was one of the fourteen candidates who competed for the honour of representing England and Wales; he was elected at the head of the poll, his colleagues being Sir Walter Foster and the late Dr. J. G. Glover. He was re-elected in 1891, but did not again seek re-election when his second period of office terminated in 1897. In 1876 he was elected a member of the Council of the Royal College of Surgeons of England, and was thus among the earliest provincial surgeons to receive this distinction, in which he had been preceded only, we believe, by Mr. George Southam, of Manchester, and Mr. Alfred Baker, of Birmingham; his term of office terminated in 1881, and he did not then seek re-election.

Mr. Wheelhouse for over fifty years took a great interest in the West Riding Medical Charitable Society, which he joined in 1855, his then partner, Mr. Garlick, being the secretary. On

Mr. Garlick's death Mr. Wheelhouse assisted his successor, Dr. Chadwick, and was subsequently appointed Secretary, holding the office in conjunction with that of Treasurer for twenty-five years. Not long ago he was succeeded as Secretary by his son-in-law, Mr. Herbert Rowe, who had been associated with him in office for some twenty years. Mr. Wheelhouse continued to act as Treasurer up to the time of his death. A few years ago he compiled the history of the origin and early years of the society, which was established in 1828. During his long term of office as Treasurer the financial position was very greatly improved; and it is characteristic of the generosity and self-forgetfulness with which he gave himself up to all work for the good of the profession that for many years under his management two items, and two items only, appeared in the balance sheet under the head of expenditure—a bill amounting to about £20 for printing, and 10s. 6d. for the purchase of a copy of the *Medical Directory*. In 1902 three hundred of his fellow members presented him with an address

of thanks, accompanied by a gold watch and chain and a silver tea service. At the last meeting of the society which he was able to attend—that which took place at the end of December, 1907—Mr. Wheelhouse stated that the amount distributed since the foundation of the society to necessitous members of the profession, their widows, and families, had reached the gratifying total of over £44,000, and that the present financial position was sound, the income from investments amounting to about £1,100, and that from subscriptions to about £750.

While still resident in Leeds Mr. Wheelhouse was a member of the Leeds Philosophical Society, before which he delivered several addresses; he was also a patron of Leeds parish church, and his name was on the Commission of the Peace for the borough. After his retirement to Filey he continued to lead an active life, and was for some time President of the Filey Conservative Association; he was churchwarden of Filey parish church, and took a great interest in its welfare. He was a school manager and chairman of the Filey Lifeboat Committee, and in other ways took an active part in local affairs. He was also a magistrate for the East Riding, and habitually presided at the local bench. He attended a meeting of the East Riding magistrates at Beverley so recently as February last, and it was, indeed, on his return from that journey that his fatal illness began; he was then seized with an attack of angina pectoris, and, although he rallied and was able to attend to his duties for some weeks, he suffered other seizures, and was entirely confined to the house for three weeks before his death.

Mr. Wheelhouse married in 1860 a daughter of the late Rev. Joseph Cowell, Vicar of Todmorden, by whom and by three daughters he is survived.

The funeral took place at Filey on April 13th, and was attended by, among others, Mr. Littlewood, Professor of Surgery, representing the University and General Infirmary, Leeds; by Mr. L. R. Braithwaite, representing the resident staff of the infirmary, and by representatives of the county and local magistrates and the urban district council. The crew of the lifeboat acted as pall bearers.

Of the personal charm of Mr. Wheelhouse, of his genial, cheery manner, the expression of a genuine kindness of heart, of his loyalty to colleagues we need not speak, for we have the good fortune to be able to print the following tribute from his former colleague, and friend of forty years, Sir Clifford Allbutt, K.C.B.:

You invite me to add some words of mine to the biography of my old friend and colleague, Wheelhouse; and not unreasonably you request me to send them by return of post, which, as it happens, leaves me three hours. Three hours to reflect upon and to sum up the memories of forty years! An "impressionist sketch" indeed it must be. By the chances of our own generation, and of our almost simultaneous election on the honorary staff of the (old) Leeds Infirmary, Wheelhouse, Mr. Pridgin Teale, and myself were brought into close association, an association so close as to be fraught with happiness or unhappiness as the case might be. It was to be for happiness; for, taken all in all, we three were brethren in a sense that was as true for none others perhaps of our time. A Cambridge graduate of those days knew no surgery; he was taught none, nor examined in any part or lot of it. To the practice and circumstance of surgery I never became inured; but its problems had a new and absorbing interest for me—a personal interest, it is true—which I venture to touch upon now only so far as to indicate how intimately I associated myself with these two colleagues in hospital work. The loss which clings to all gain—one loss which aseptic surgery has brought with its prodigious gain—is the disruption of the old custom of co-operative surgery. What had made Leeds a great surgical school was this practice in common: the fixed operating days and hours, when, so far as engagements permitted—and they were generally forced to permit it—all the honorary surgical staff used to collect and to work together in mutual aid, mutual counsel, and, moreover, in that outspoken mutual criticism which is possible with loyal allies. Samuel

Smith, "Tom" Teale, and Samuel Hey were continuing and broadening down the great traditions of the place; Wheelhouse and Mr. Pridgin Teale were audacious juniors—Wheelhouse audacious by the breadth and security of extraordinary practical and theoretical knowledge, Teale by—but I must stop lest he overhear me; his friends know what I would say. And they also know that with these strong links that chain of great surgery was forged onwards in Leeds, which is growing as actively as ever to-day. On these operating days I was often an onlooker, and thus cemented a community of interests as well as a bond of affection with my two nearer contemporaries which never knew an hour's chill, never a breath of misgiving.

As illustrations of Wheelhouse's apparent audacity, the boldness of a man for whom all formal surgical knowledge was personal knowledge, I may refer to two operations—two out of many, and no doubt better, instances—but chosen because I was concerned in them; these were his often-quoted first paracentesis pericardii, and a suture of the great sciatic, a device now common enough, but in those days scarcely attempted. This patient, who, by sitting down upon a scythe divided his sciatic nerve, came to the hospital with a healed scar and a palsied limb. Wheelhouse promptly excised the scar, and repaired the nerve with complete success. In the other case, also in the old infirmary, I called up Wheelhouse—my surgeon of the week—suddenly in the night from his bed, and showed to him a young man with acute pericardial effusion, then in the jaws of death. All I had to say was: "Here is this man dying of a pericardial effusion. What you have got to do is to remove it. How you will do it is your affair." There was no time for questions or books, maps, or records; the steady hand had to strike, and to strike exactly with the right weapon and exactly in the right place. This was done unhesitatingly, and the patient's recovery, which began from that moment, was complete. At any rate, for some years later we saw him occasionally in the pursuit of his calling, and in good health. These are small matters perhaps in the brilliant light of modern surgery, but I am speaking of things now some forty years ago.

Wheelhouse's surgery was, as I have said, the sure practice of an anatomist and craftsman who learnt everything and forgot nothing; not only so, but of a man whose mind was so orderly and precise that every detail of that learning was continually before his eyes, and standing in its proper relation to other things. He advised or operated as a man may walk over mountains who had previously surveyed every inch of the country and had all the map in his head. To others it may seem audacity or magic, to himself just business. This orderliness and precision were no less manifest in all the work and engagements of his full and strenuous life; and, what was no less surprising—if I may venture for the moment to speak on behalf of the bad memories and disorderly minds—he seemed none, or but little, the worse for it. Your orderliness is apt to turn to primness and rigidity, your good memory to become a sort of beehive in which one bee is as good as another, and in which, indeed, a good deal of rubbish as well as honey is apt to gather. But if Wheelhouse's mind was rather comprehensive and instructed than original, yet, as was the case with Scattergood, whose qualities were not dissimilar, his ear was always open for progressive ideas, and he could always see over the top of his many careful rows of pigeon-holes.

We used to rally Wheelhouse on his adherence to some considerable part in general practice; and no doubt if he had discarded it, he would have made a bigger reputation as a surgeon. But for family and personal practice he had gifts too great, as he was probably aware, to be laid up in a napkin. His strong, sure, accurate, and kindly mind found expression in his manner and speech, in a somewhat formal but friendly, concentrated, trusty fashion of giving help and counsel.

How well we all remember his ways with a tiresome or sorrowful hospital patient, or with a tiresome colleague who did not happen to agree with him. How he would draw his chair nearer, fix one with his myopic glasses, lay a persuasive hand on one's shoulder, as if there were but one way in the whole world of regarding the matter; and as if, moreover, temperament temper, emotion, vexation,

* I do not forget our brilliant young colleague, Dr. Hardwicke, but swift death soon took him from us.

and so forth, did not exist; and then would not argue with us, not at all, but would just tell us, in slow-measured words, what we had got to do and even to think. And the worst of it was, the dear, kind, good fellow was always mainly, and, for the most part, altogether right. Such strong succour as this was precious indeed to his suffering or bereaved patients, and no man gave his services to them more generously or more unostentatiously.

Morning, noon, and night after night he laboured, making a rich harvest indeed, but not of money. Perhaps few men ever worked so loyally and so simply for others, and for so little pecuniary reward. Methodical in all else, he never seemed to lay any plans for money making; and when to his other engagements he added the office of Surgeon to the Midland Railway Company, even Wheelhouse's enormous capacity for work was tried to the full. How well I remember one day seeing his carriage forging slowly up a hill out of Leeds, with the horses half asleep, the coachman more than half asleep on the box, and Wheelhouse himself fast asleep inside. One foggy night, worn out with fatigue, he was called at a late hour to Wakefield. He fell asleep in the carriage, was taken to Wakefield and carried back again to Leeds, where the coach was shunted; later still it was made up into another train and returned to Wakefield, where the sleeper, hearing the call, stepped gaily out, to find it was 2.30 a.m., and no train home again that night. But next morning there was an early lecture, so he procured a cab, but, owing to the fog, had to walk most of the eight miles home, carrying a lamp to show the horse the way.

His Presidency of the Association at Leeds can scarcely pass without mention in these recollections. Ardent worker for the Association as he had been, he never schemed for the Presidency. In his own methodical and just way he informed me—yet, as I used to tell him afterwards, with a rather wistful look in his face—that by the conventional precedence of medicine before surgery, the office was mine. High-minded man as he was, he left it to me to recall his seniority in years and, far more than this, the long and loyal services he had rendered to the Association, services far greater than any other man in the Riding, and, furthermore, his gifts for business and organization, in which he surpassed us all. When I stipulated only for the office of proposing him for the Presidency he accepted the position frankly and gladly, and discharged its duties admirably, as we knew he would.

Nor, again, can I forbear to allude, if it can be no more than allusion, to the remarkable and perhaps unique West Riding Medical Charitable Society. If the task of nurturing this society in its early years belonged to others, to none more perhaps than to Chadwick—yet its earlier nurses handed it over to Wheelhouse as a wise and powerful guardian. How under his fostering care its growth and prosperity grew more and more was warmly testified to at a meeting of his colleagues a few years ago. We men of the West Riding who have seen the beneficence of this society fail to understand how it can be that other counties of the United Kingdom have not gone and done likewise.

Wheelhouse was too thoughtful a man to suppose that labours like his could be carried on into the autumn of life; with his habitual precision he had decided to retire at sixty, and it was only a few years after this age that he withdrew from practice and retired to his eyrie at Filey.

How there among the coastguardsmen and seamen he nevertheless made his great qualities felt, and became, after a fashion, in county business as necessary to his East Riding neighbours as he had been to us in the West, is well known, and is a story I am less well able to tell. What I can say is that my old friend—our old friend—lived to a ripe age, a simple and magnanimous, wise and courteous, useful and charitable, and, I believe, as he well deserved, a very happy life.

We are indebted to Mr. T. PRIDGIN TEALE, F.R.S., for the following note of appreciation:

My association with Mr. Wheelhouse began in 1856, when, on commencing practice in Leeds, I joined him in the teaching of anatomy at the Leeds School of Medicine. Our association in work for the school and infirmary was very close, constant, and cordial, and lasted until, at the end of our twenty years as colleagues at the infirmary, we accepted retirement as consulting surgeons, with the

privilege of using six beds each, when the need for our co-operation in teaching ceased. A few years later he retired to his charming cottage at Filey. It is not too much to say that Wheelhouse did more than any single individual to hold up the Leeds School of Medicine at a very critical time.

As a lecturer he was clear, accurate, and interesting, and able to command the attention of his class. He had a remarkable memory, and was able to work hard without worry. Few people worked as hard, as continuously, or for as long hours as he did during the greater part of his professional life.

Coming to Leeds an unknown youth with a widowed mother, and commencing his career as a hard-worked assistant in general practice, he achieved first his position as a Lecturer on Anatomy at the Medical School. He then became Surgeon to the Infirmary, was returned as one of the first Direct Representatives on the General Medical Council, was Chairman of Council of the British Medical Association, was elected to the Council of the Royal College of Surgeons, and finally President of the British Medical Association at its meeting in Leeds in 1889. Such a position is eloquent testimony to the high value set by his medical brethren on his professional acquirements, his personal integrity, and his exceptional capacity as a man of business.

On his retirement to Filey, in good health and mental vigour, he still devoted his trained energy and experience to good public work in his adopted town, and to the district as a county magistrate.

Dr. A. T. H. WATERS, who was President of the Association in 1883, the year in which the annual meeting was held at Liverpool, writes:

The death of Mr. Wheelhouse removes from amongst us a prominent figure in the Association and one to whom the Association is largely indebted. It must be nearly, if not quite, fifty years since I first met him as a member of the Committee of Council of the Association. We used to meet in Birmingham once a quarter, and no one was more active or took a greater interest in the welfare of the Association than Mr. Wheelhouse. He was a good speaker, a thoroughly good man of business, and he made an excellent President of Council during his years of office 1881-4. He was one of the group of men who during the Sixties and Seventies and later on devoted a great deal of time and energy to promote the progress and interests of the Association, and whose efforts were crowned with success. For many years I used to meet him at the annual and quarterly meetings, and it is a satisfaction to me, as a survivor of the group I have referred to, and one of the oldest members of the Association, which I joined in 1854, to give expression to my feelings on the loss we have sustained. Mr. Wheelhouse was a man of high principle, and he possessed great personal charm. His work deserves full recognition.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on March 24th.

Recognition of Teachers.

The following were recognized as teachers of the university in the subjects indicated:

Middlesex Hospital Medical School.—Dr. Reginald John Gladstone (Embryology).

London School of Medicine for Women.—Miss Helen Chambers (Pathology and Bacteriology); Mr. Leonard S. Dudgeon (Pathology).

Physiological Laboratory.

Dr. Waller was reappointed director and Dr. Mears treasurer of the Physiological Laboratory for the year 1909-10, and Sir Lauder Brunton was appointed a member of the Physiological Laboratory Committee for the remainder of the period 1908-9 in the place of Dr. Pre-Smith, resigned.

The annual report of the Physiological Laboratory Committee which was presented stated that three courses of eight lectures each had been delivered. The lectures on the therapeutics of circulation delivered by Sir Lauder Brunton, and on the intracellular enzymes by Dr. H. M. Vernon, had, with the authorization of the Senate, been published by Mr. John Murray. The report also contained a list of published papers, the outcome of work conducted in the laboratory.

Dr. Arthur Harden, D.Sc., Ph.D., was added to the panel of lecturers in physiology.

Reappointments.

Professor E. H. Starling, M.D., F.R.S., has been reappointed the representative of the Faculty of Medicine on the Senate, and the Faculty of Science has reappointed Professor Sir William Ramsay, K.C.B., M.D., F.R.S., as one of its representatives.

Sir John Williams, K.C.V.O., M.D., has been re-elected for a further period of five years as the Chancellor's representative on the Court of Governors of the University College of South Wales and Monmouthshire.

Exemptions in Regulations for Medical Degrees.

It was resolved that Section 5 (iv) of the exemptions from the normal course of study and examinations for internal students (Red Book, September, 1908, appendix to regulations in medicine, p. v) and Section 5 (iii) of the exemptions for external students (Blue Book, September, 1908, appendix to regulations in medicine, p. iv) be amended to read as follows:

Students who have passed or entered for the preliminary scientific examination, Part I, or the first examination for medical degrees, in or before July, 1910, will be permitted to enter for the third examination for medical degrees after a period of not less than two academic years from the date of their passing in anatomy and physiology at the intermediate examination in medicine or at the second examination for medical degrees, Part II, provided they satisfy the regulations in other respects.

Presentation Day.

The presentation of graduates will take place at the university at 5 p.m. on Wednesday, May 12th.

Studentships in Physiology.

Applications for the Lindley Studentship, of the value of £100, to be awarded to a student qualified to undertake research in physiology, must reach the university not later than May 1st.

The University Studentship, of the value of £50 for one year, will be awarded to a student qualified to undertake research in physiology, and will be tenable in the Physiological Laboratory of the university or of a school of the university. Applications must be received by the Principal on or before May 31st.

Advanced Lectures in Physiology.

The following courses of advanced lectures in physiology will be delivered during the third term:

Eight lectures on the Chemical Biology of the Yeast Cell will be given by Dr. Arthur Harden on Tuesdays, at 5 p.m., beginning on May 4th.

Eight lectures on Nerve Cells and Nerve Fibres, by Dr. W. Page May, at University College, on Wednesdays at 5 p.m.

Eight lectures on Recent Advances in Physiology, by Professor E. H. Starling, F.R.S., at University College, on Fridays at 5 p.m., beginning on May 14th.

Eight lectures on the Senses of Hearing, Smell, and Taste, by Dr. C. S. Myers, at King's College, on Fridays at 4.30 p.m., beginning on May 7th.

Four lectures on the Secretion of Urine, by Dr. T. G. Brodie, F.R.S., at King's College, on Mondays at 4.30 p.m., beginning on June 7th.

Four lectures on the Regulation of Respiration, by Dr. J. S. Haldane, F.R.S., at Guy's Hospital Medical School, on Thursdays at 4 p.m., beginning on May 6th.

Four lectures on the Accessory Factors of an Efficient Diet, by Dr. F. G. Hopkins, F.R.S., at Guy's Hospital Medical School, on Thursdays at 4 p.m., beginning on June 3rd.

Four lectures on Statistical Methods in Physiology and Medicine, by Mr. M. Greenwood at the London Hospital Medical College on Fridays at 4.30 p.m., beginning on May 21st.

Courses (1) (2) (3) and (4) have been recognized by the Senate as courses of advanced lectures which a candidate at the B.Sc. (Honours) examination in physiology may name for part of his practical examination.

Lectures by Professor of Protozoology.

A course of twenty-three lectures on protozoa will be given at the Lister Institute, Chelsea, by Professor E. A. Minchin, at 5 p.m. on Mondays, Wednesdays, and Fridays, during May and June, beginning on May 3rd.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

Sir Patrick Manson will deliver a course of ten lectures on Tropical Diseases illustrated by lantern slides, on Tuesdays at 4.30 p.m., beginning on May 4th.

UNIVERSITY OF ABERDEEN.**DEGREE DAY.**

The following were among the degrees conferred on April 6th:

M.D.—W. Angus, R. Chalmers, H. W. A. Cowan, J. A. Davidson, R. E. Beffan, A. Skinner, M.A.

Ch.M.—J. Robertson.

M.B., Ch.B.—A. G. Anderson, M.A., W. Anderson, D. M. Baillie, J. A. Beattie, J. C. Bell, D. W. Bruce, A. J. D. Cameron, A. H. Dugiet, W. Dugiet, N. Dunn, M.A., J. Elder, J. D. Fildes, M.A., B.Sc., G. C. Grant, A. Gray, H. Hargreaves, J. Inkster, W. W. Jameson, M.A., H. G. R. Jamieson, J. Johnston, C. R. Macleod, J. McPherson, A. Macrae, C. A. Masson, M.A., J. L. Menzies, R. J. Menzies, H. S. Milne, D. C. Mitchell, D. C. Robinson, F. G. M. Ross, H. A. Smith, G. C. Souter, D. M. Spring, A. G. Stewart, M.A., R. Sturrock, C. C. T. Cwort, J. J. Williamson, M.A., A. Wilson.

On the same occasion Diplomas in Public Health were handed to:

Messrs. G. Davidson, J. Ferries, A. F. MacBean, M.A., R. McRae, A. J. Milne, W. G. Watt, T. C. McO. Young.

In medical colleges of Aberdeen honours for thesis.

1 Second class honours.

VICTORIA UNIVERSITY OF MANCHESTER.**DEGREE DAY.**

At a degree ceremony held in the Whitworth Hall on March 31st, Professor Stirling, as pro-Vice-Chancellor, admitted a number of graduates to the roll.

Professor Hickson presented for the degree of M.A. Mr. S. Saloman. Principal Reynolds presented for the degree of Master of Technical Science Mr. W. Crump and Mr. C. F. Smith. Mr. W. Sims presented Mr. A. Reuben for the degree of Bachelor of Dental Surgery. Sir W. Sinclair presented the following for the degree of Bachelor of Medicine and Surgery: B. W. E. Trevor-Roper (second-class honours), J. A. Bateman, N. Booth, J. I. Halsead, E. Howe, M. C. S. Lawrance, T. M. Pople, J. Ramsbottom, W. V. Utley, H. V. White, and J. Whitehead.

Professor Stirling expressed regret at the absence of the Vice-Chancellor, and hoped that his holiday in the East would enable him to recover his usual health. Professor Stirling said he thought that the menu of studies placed before the medical student was too elaborate and overcrowded. His mental digestion would be improved if some of the items were struck out or simplified. One wondered whether the products of his mental digestion were ever assimilated. Access to the profession of medicine was, perhaps, the most difficult of all, for the aspirants had to devote at least five years to arduous studies. Though medicine could not be considered an exact science, it was based on science, and every day its progress as a practical art was becoming more and more dependent on the advances made by the sciences on which it was based. In no department had the knowledge of causes produced such a revolution as in that of surgery. A similar success would be soon obtained in medicine if the public would only waken up to its responsibilities. Ague had disappeared, hydrophobia was almost non-existent, cholera and plague had been banished from our shores, and malaria and yellow fever were under control. Consumption, however, still claimed its victims in thousands, and the apathy of the public was extraordinary. Professor Stirling recommended to his hearers the cultivation of hobbies, and went on to speak of the serious nature of the medical profession. Manchester, he said, possessed almost unrivalled opportunities for the study of medicine and surgery in its numerous hospitals, and he thought that Oxford Road might well be renamed the *Boulevard des Hôpitaux*. He referred to the new Dental Hospital, and said that the day marked a new era in the history of the school of dentistry, as the degree of Bachelor of Dental Surgery had been conferred for the first time. In concluding, Professor Stirling referred to the deaths of Dr. T. Harris, Professor Dreschfeld, and Mr. Collier, and the retirement of Professor Young. He also gave expression to the regret caused by the death of Professor Gamgee, to whom the medical school owed so much.

THE UNIVERSITY OF LIVERPOOL.**DIPLOMA IN TROPICAL MEDICINE.**

The following candidates have been approved at the examination for the "Diploma in Tropical Medicine":

R. G. Abercrombie, J. R. P. Allen, H. P. W. Barrow, P. Carr-White, W. S. Clark, R. Cope, W. D. Hayward, W. P. Meldrum, J. C. Murphy, M. G. Samuel, M. H. Thornely, W. S. Webb.

UNIVERSITY OF DURHAM.**DEGREE DAY.**

At a Convocation on April 3rd the following degrees were conferred:

M.D. (ordinary)—G. I. Cumberlege, R. A. Morris, W. W. Stainthorpe, P. E. Turner.

M.D. (for practitioners of fifteen years' standing)—G. T. B. Ellick, A. A. Hill, B. W. G. Masterman, E. J. F. Moore, J. P. Oliver, W. J. E. Supton.

M.S.—B. Glending.

M.B.—K. B. Allan, Harriett A. R. Apps, E. C. Braithwaite, L. F. Browne, C. E. L. Burnman, L. W. Evans, J. R. D. Holby, H. F. Hewier, D. M. Johnston, Annie V. Mack, Jessie M. Murray, F. Rahnke, W. Rollin, R. H. Smallwood, T. W. Stallybrass.

B.S.—K. B. Allan, Harriett A. Apps, E. C. Braithwaite, L. F. Browne, C. E. L. Burnman, L. W. Evans, J. R. D. Holby, H. F. Hewier, D. M. Johnston, Annie V. Mack, Jessie M. Murray, F. Rahnke, W. Rollin, R. H. Smallwood, T. W. Stallybrass.

B.Hy.—G. R. East, J. T. Johnson, W. R. Macdonald, Elizabeth N. Neil, A. J. R. O'Brien, Gertrude E. O'Brien.

EXAMINATION RESULTS.

The name of Mr. Edward Phillips, of the London Hospital, was accidentally omitted from the list of successful candidates at various stages on the examinations for the M.B. degree, published at page 981 of our issue for April 3rd. He was one of the only two candidates successful in all four subjects of the First M.B. (elementary anatomy and biology, chemistry, and physics), and was awarded honours.

LONDON SCHOOL OF TROPICAL MEDICINE.

The following candidates were approved at the examination held at the end of the twenty-ninth session:

* J. A. Beamish, † T. Davenport Jones (Captain, I.M.S.), * G. M. Gray, † L. Gammie, † J. McDonald Major, † J. S. Winsor, † J. W. Archibald, Dora Watney, † M. E. Franklin, D. C. Master, R. Mortimer Johnson, † T. Hood Rankin, † C. W. O'Keefe, J. C. Spillane, † F. Lumb, † A. W. Grant, † G. B. Mason, A. H. Ezyee, R. C. Tilgner.

* Passed with distinction.

† Colonial Service.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL are at 429, Strand, London.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "Engineer," and so on. By attention to this request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

TREATMENT OF RINGWORM IN SCHOOL CHILDREN.

DR. E. SCOTT GALBRAITH, D.F.H.Lond. (The Education Offices, York), writes: The treatment and cure of ringworm are engaging the attention of a vast number of medical men throughout the country at the present time. This disease is recognized as being one of the most intractable, if not the most intractable, with which the elementary school child is affected. It might be said to be the most prevalent disease amongst this section of the community. It is extremely contagious. It has a lengthy duration, at any rate when situated in the scalp, is never of itself fatal and it tends eventually to disappear. The seriousness of the complaint seems to lie in its contagiousness and the temporary disfigurement. It cannot give rise to much annoyance, as children attacked by it scarcely ever make complaint. It may have as sequelae thinness of the hair and baldness, but if this were always so one would expect to see a far larger number of bald children than is actually seen considering the huge number who are affected with tinea tonsurans. The fact of its prevalence and contagiousness makes it an efficient treatment a matter of most urgent importance, and it is this which has led me to write to you in the hope that some of your readers may be influenced in giving the results of their experience and thereby help in clearing up the doubt and difficulty under which some of us labour. Sabouraud, whose investigations are of the highest interest and whose knowledge of the disease is second to none, claims to have had marvellous results in the treatment of ringworm at the St. Louis Hospital, Paris, by the use of x rays. Likewise at the skin department of the London Hospital treatment by Roentgen rays has been attended with great success. The Metropolitan Asylums Board, the Bradford Union Hospital, and other institutions in England have been very successful in their electrotherapeutic treatment of ringworm. Notwithstanding these results there are many leading members of the profession who view with disfavour x-ray treatment. Dr. P. S. Abrahams, surgeon, West London Hospital, did not advocate its use in his post-graduate lectures delivered some months past. He prefers drug treatment. Dr. Dawson Turner has issued a warning against the decision of the Education Committee of the London County Council in favour of the treatment of ringworm by x rays, and the compulsory attendance of children for this treatment. I, for one, would like to know of a method of treatment by drugs which would show such good results as are claimed by some x-ray surgeons.

ANSWERS.

J. H. P.—We know of no ground for the statement that aspirin produces alkalinity of the urine. Aspirin has twice the alkalinizing power of the corresponding amount of salicylic acid, one equivalent of alkali being neutralized by the acetic and one by the salicylic acid.

BOOKS ON RADIOGRAPHY.

X-RAY asks for the titles of one or two elementary books on the theory and practice of x-ray work and the Finsen light.

*. An elementary work is the *Uses of Roentgen Rays in General Practice*, by Dr. Higham Cooper (London: Baillière, Tindall, and Cox. 1906. 2s. 6d.). It is not such a book as an expert would use, but it indicates in plain language the scope of x rays for general medical practitioners. A book which covers the ground very thoroughly is Drs. Arthur and Muir's *Manual of Radiology* (London: Rebbman, Ltd. 1909), published a few months ago. Finsen light literature is not so extensive. Dr. Sequeira's translation of Finsen's book, *Phototherapy*, is published by E. Arnold (1901. 4s. 6d.), and a small handbook on *Medical Electricity and the Light Treatment* has been issued by the Scientific Press. *Light and X-ray Treatment of Skin Diseases*, by Morris and Dore (London: Cassell and Co. 1907. 5s.), is a standard work on the subject.

LETTERS, NOTES, ETC.

DIPTEROUS LARVAE INFECTION.

DR. K. GRON (Municipal Infirmary, Ullevaal, Christiania) writes: The interesting communication of Mr. Stephen M. Laurence, in the BRITISH MEDICAL JOURNAL of January 9th, 1909, p. 88, on dipterous larvae infection, has caused me to remember that a few years ago I saw a case resembling it. The patient was an unmarried woman, aged 68 years, who, for cancer of both breasts (*cancer en cuirasse*), was attended at the Municipal Infirmary of Christiania from June 22nd to her death on December 28th, 1907. On December 27th a number of greyish maggots, about 1 cm. long, were observed moving vigorously in the patient's bed; the same thing had been observed by the nurse on an earlier occasion, and for a long time a remarkably large number of flies had been seen in the neighbourhood of the bed. On investigation it was found that the maggots had their dwelling place in the partly necrotic mass of cancer and had penetrated to some depth: they were especially numerous about the nipple of the left breast. In different places openings were found, and through these the maggots could be seen moving in and out. The case was treated with a 50 per cent. solution of lysol, which was changed thrice daily, and two days later the maggots disappeared, or at least could no longer be seen, although on the previous day two had been seen. I believe that the application of the lysol solution had destroyed the maggots, and considered the experience worthy of record on account of the relative rarity of such cases.

PROFESSIONAL SECRECY.

The following fine example of strict observance of the code of professional honour was reported in the *Evening Standard* and *St. James's Gazette* a short time ago. It purports to be taken from that trustworthy source, the *Petit (sic) République*. After some statements about the health of the Pope, it is added: "It is also affirmed that His Holiness is suffering from diabetes, but Dr. Lapponi preserves strict professional silence on the point." As Dr. Lapponi died some four years ago, and, we believe, is still dead, the report of his secrecy may probably be accepted. We say "probably," as before he passed beyond the veil he wrote a book on spiritism and hypnotism, and doubtless there are many ready to believe that he is still in a position to supply information to adepts in spirit rapping. It is all the more to his credit, therefore, that, being beyond the reach of any ethical tribunal, he has refused to break the seal of professional secrecy.

THE CAUSATION OF INGROWING TOENAIL AND THE NEMO (Edinburgh) WATER.

DR. J. JOHNSTON (Bolton) writes: From experience I am of opinion that ingrowing toenail is most liable to occur in those persons who are in the habit of taking hot baths in the morning or through the day. The toenails are "softened" by the hot water and may then be distorted by the use of tightly fitting boots. After a hot bath the toenails should be "hardened" by allowing cold water to flow over them for a time.

AURAL IMPLICATIONS.

DR. J. JOHNSTON (Bolton) writes: The case reported by Dr. Esslemont (BRITISH MEDICAL JOURNAL, February 20th, 1909), in which a cherry stone was impacted in the ear for twenty years, recalls a case of mine in which a foreign body has been impacted in the ear for thirty years. In 1879 a little boy of 7 was brought to me with a small glass bead which had been pushed right down into his ear. During my attempts to syringe it out he began to be violently sick, whereupon his mother, seeing what he was vomiting, exclaimed: "There's where my black currants 'as gone." An' then 'e said them 'adn't touched 'em." This unexpected development so upset the boy that he absolutely refused to permit any further treatment, and he has refused it from that day to this, and the bead is still there! But the curious thing is that its presence has had no effect upon his hearing. I saw him the other day, felt the bead with a probe, and he declared that he could hear quite well with that ear. He still declines further efforts for the removal of the bead by syringing.

ERRATUM.

In the obituary notice of Dr. Arthur Gamgee in last week's issue of the JOURNAL, page 934, col. 1, line 15 from foot, the words "lecture-address" should have been "Latin address."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	—	—	0 4 0
Each additional line	—	—	0 0 6
A whole column	—	—	2 13 0
A page	—	—	8 0 0

An average line contains six words.

All remittances by Post Office Order must be made payable to the British Medical Association, 429, Strand, London, W.C.2. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Poste Restantes* addressed either in initials or numbers.

An Address

ON

GENERAL PRINCIPLES IN THE TREATMENT OF DISEASES OF THE HEART.

DELIVERED AT A MEETING OF THE HUDDERSFIELD
DIVISION OF THE YORKSHIRE BRANCH OF THE
BRITISH MEDICAL ASSOCIATION.

BY SIR JAMES BARR, M.D., LL.D., F.R.C.P.,
F.R.S.E.,

SENIOR PHYSICIAN, LIVERPOOL ROYAL INFIRMARY.

GENTLEMEN,—When I undertook to address a Yorkshire audience I at once thought it wise to select a subject which would appeal to their sense of practical utility, and, rightly or wrongly, I considered that, even by a non-emotional race, no subject would be more likely to receive an attentive hearing than that of the treatment of heart disease. Although you may not be very liable to emotional disturbances of the heart, I believe the common affections of that organ are not at all uncommon in this part of the kingdom, if I be rightly informed by a distinguished Yorkshire physician, Sir Thomas Clifford Allbutt.

In dealing with a subject I always like to look at it through my own spectacles, as I imagine they are specially constructed to take in a wide horizon, and in the treatment of disease I like to get ahead, and, when possible, treat the patient before the disease arrives. This is fortunately often possible in the case of diseases of the heart, though I do not wish you for a moment to think that I am one of those who say "that if they had only been called in an hour sooner they might have prevented the disease or saved the patient." I do not like to cut things quite so fine as that, though in some heart affections a few seconds are often of vast importance. The age of prevention is gradually dawning, and I have no doubt the time will come when questions of health will receive much more consideration than those of disease. When the millennium arrives all our huge hospitals will be empty, and remain only as relics of an ignorant age. The human species will devote as much attention to the production of healthy offspring as is now spent in the rearing of colts, and the human organism will know how to adapt itself to the environment.

No doubt the majority of sudden deaths arise from cardiac failure, but there are very few chronic diseases so amenable to treatment and so compatible with a long life of comfort if judiciously handled as those of the heart. In dealing with the prevention of diseases of the heart there are two very large and wide classes which will require our consideration, namely, those arising from or associated with some acute disease, such as rheumatism, and secondly, those degenerative lesions of the heart and vessels which are so common in later life. Regarding the prevention of congenital heart lesions, I shall at present leave that to those who are well versed in Mendelian laws, or who follow the biometric system, but I may be allowed to express the hope that the State will soon arrive at a sense of its duty, not merely in inculcating the teaching of eugenics, but that it will also adopt some salutary laws in preventing the propagation of the unfit.

Of all the acute diseases which give rise to heart disease rheumatism holds the first place, and shall therefore receive our primary attention. The young, and especially those with any hereditary tendency to rheumatism, should be warmly clothed; they should have daily ablutions, either temperate or cold, according to the susceptibilities of the individual; they should have an abundance of fresh air night and day; they should avoid all overcrowded rooms; there should be sufficient exercise in the open air; there should be at least one free evacuation of the bowels daily; all febrile disturbances, especially sore throats, should receive prompt attention; the condition of the digestive tract and the nature of the in-put require consideration. The family attendant should frequently inculcate the general principles of hygiene, otherwise he will not have much opportunity of preventing rheumatism, as perhaps the majority of parents are so callous, careless, ignorant, or unobservant that large numbers of cases of

rheumatism are passed over as "growing pains" until perhaps some serious heart lesion is developed. Preventive work is often very thankless and unremunerative, and those who attempt it are frequently described as faddy, meddlesome alarmists, trying to prevent diseases which might never occur, but you will always have the moral reward of having done your duty.

A wise man leaves as little to chance as he can help. He may undertake any dangerous occupation; but if working in a powder magazine it would be prudent to see that there is no naked light about. So parents who have transmitted a rheumatic tendency to their offspring should feel in duty bound to prevent any explosion. It would as a rule be more profitable for parents to pay their medical attendants for looking after the health of their families rather than for treating their diseases. This does not mean coddling, as a healthy child may undertake any game commensurate with its physical capacity, and, for the moral and physical evolution of a child, the more risky the game the better for the child's character. There should be due recognition of the risks, and all possible precautions taken to prevent accidents; but accidents will occur, and, if due precautions have been taken, even rheumatism might be treated as an accident. If you have failed to prevent the accidental occurrence of rheumatism, then you should be prepared to treat it energetically so as to prevent the subsequent occurrence of heart mischief. Treatment should as far as possible be dietetic and hygienic, because you cannot keep any patient for long periods constantly under the influence of drugs, and the action of drugs can be materially assisted by suitable diet.

In rheumatic fever there is a marked increase in the formation of sarcolactic acid, and all the excretions are very acid; I therefore think it advisable to omit all foods, such as starch and milk, which give rise to the formation of lactic acid in the digestive tract. There is also a great tendency to the formation of fibrin; hence, everything containing lime, such as milk, and all preparations of milk, cheese, gelatine, and animal jellies should be strictly interdicted. Lime also raises the blood pressure, and so increases the strain on the valves. I know that I am here running counter to the general advice of the profession, as with most medical men milk is their sheet anchor in their diet for this disease, but I condemned it in 1886, and I have consistently done so ever since. A great many medical men are like the Yankee, who did not know anything about measles but was death upon fits, so they make no attempt to prevent the rheumatism, or endocarditis and pericarditis; but when the latter occur they are all alert and quite prepared to give you a learned disquisition on the treatment of these two complications. One of the most recent evolutions in the treatment of pericarditis is to wait till there are some recent adhesions and then start with injections of fibrolysin, without any very convincing proof that it is able to resolve even recent scar tissue. Personally I prefer to prevent the adhesions by cutting the lime salts out of the diet, and making free use of decalcifying agents. Milk should not only be interdicted in acute rheumatism, but also in the subsequent treatment of the heart lesions.

An excellent diet for rheumatic fever consists of plenty of hot water, mincemeat and poached egg, pounded chicken, steamed sole, and other nitrogenous articles of diet. If any carbohydrate be required, well-boiled porridge may be given; the silicates in the oatmeal have a decalcifying effect. I am also very fond of syrup of glucose (free from arsenic), which is very palatable when administered with infusion of orange. This, unlike cane and milk sugar, does not readily undergo lactic acid fermentation. Oranges and lemons may be freely used. When the rheumatic attack is over, the diet may be more varied; there may be allowed a fair amount of farinaceous food, and plenty of fruit and vegetables, but milk should still be eliminated. There are two classes of rheumatic patients in whom you will find heart disease—the fat, flabby, lethargic, and somewhat phlegmatic individuals who like their food and do not care for much exercise, and, on the other hand, the very spare, active, rather neurotic individuals who do not over-indulge in the good things of this life; this latter class wears much better, and this knowledge should help you in directing your diet, which should be light and nutritious, with a fair allowance

of meat, fruit, and vegetables, and not much starchy food. The food should be merely sufficient in quality and quantity to maintain healthy nutrition; if the patient is laying on fat, the food is too abundant. I am in the habit of advising patients with mitral lesions to drink as little fluid as possible—not more than 2 pints a day—and if the tissues be at all flabby, or there be any venous engorgement, I frequently reduce them to half this amount. All fluids drunk have to pass through the right side of the heart before they are excreted (except what is carried off by purgation), and any excessive amount only handicaps it without producing any benefit. I know that some physicians like to drench their patients, with the view of washing away effete products, but it is a much wiser plan to keep the patient on a light dry diet, and not produce more effete products than can be excreted without flushing. The regular use of all alcoholic drinks should be strictly interdicted, tea and coffee with cream may be left to the discretion of the patient, except so far as the quantity of fluid is concerned. Lemon squash makes an excellent drink. Tobacco should be forbidden. If there be any tendency to oedema the salt should be cut down or eliminated from the diet.

HYGIENE.

During the endocarditis there should be prolonged rest in bed, and the blood pressure kept as low as possible. When the acute cardiac condition has passed and compensation is fairly established then a moderate amount of exercise is highly beneficial. The mode of life should be prophylactic against attacks of rheumatism. The patient should be warmly clothed with flannel next the skin, and he should avoid all vicissitudes of climate. When at any time the feet are damp or the body wet and chilled the clothing should be changed and the surface circulation re-established as quickly as possible. The action of the skin should be maintained, and for this purpose daily ablutions are necessary. A morning bath at a temperature from 60° to 90° F., according to the susceptibility of the patient, with coarse friction afterwards, will be found very advantageous. The combustion within the system should be as thorough as possible, and with this end in view the patient should avoid all close, heated atmospheres, and live as much as possible in the open air. A warm dry climate is best. He should not live at too great an elevation from the sea level so as to obviate the effects of a rarefied atmosphere, which leads to pulmonary congestion, and further tasks an overworked right ventricle. The life should be at a low level, not merely as far as the heart's surface is concerned, but in every other respect, and free from all mental worry and care. The patient should be enjoined to pursue the even tenor of his way in a happy and contented frame of mind, and simple pleasurable emotions should not be forbidden. Marriage cannot be recommended, and especially in the case of a female a timely counsel against wedlock and its usual results will be advisable. In my experience advice of this kind is very seldom taken, but at any rate I think the propagation of the species should be left to those more likely to improve the breed.

Short of actual fatigue, a fair amount of exercise, even to the extent of hill-climbing, will prove highly beneficial by favouring the circulation, increasing the combustion, and improving the general nutrition. The skeletal muscles contain about a fourth of the whole blood of the body, and exercise greatly increases the circulation through them and so increases the capillary area. On the other hand, if they be not used they require very little nutrition, comparatively little blood passes through them, as it tends to flow in the direction of least resistance; thus the capillary area is diminished and the general arterial tension raised. When, however, any indication of failure of compensation in the right side of the heart occurs, there must be no fashionable treatment by graduated exercise on a mountain side, but the excellent old-fashioned restorative of rest in bed must be at once adopted. If the disease be in the early stage, a few days' rest, a dry diet, and a cholagogue cathartic may be all that are required to restore the *status quo ante*. If a long stay in bed be deemed advisable, then massage should be substituted for the loss of muscular exercise. This improves the circulation in the muscles, increases the quantity of blood in the systemic vessels, and so indirectly lessens the pulmonary engorgement, and it hastens the

return venous current. The Nauheim treatment is best suited for patients with imaginary heart lesions and for those who have been gorging too freely.

REST.

During the acute stage of rheumatism and endocarditis absolute rest in bed is essential, but you must not imagine that because the patient's systemic muscles are resting therefore the heart has got very little to do. It is true that it has only got to pump the blood along the level, but if the blood pressure be maintained at a high level from the retention of effete materials or any other cause then the heart has got too much to do. Endocarditis attacks the valves of the left side of the heart much more frequently than those of the right, not because they are more vulnerable but because they are subjected to greater stress, and the parts of the mitral and aortic valves which are brought into most violent apposition during their closure are the parts first affected, hence the rows of beaded vegetations due to proliferation of the subendothelial layer appear on the auricular surface of the mitral valve and on the ventricular surface of the aortic valve. Rest in bed in a case of rheumatic fever is neither sufficient to prevent endocarditis nor to cure it, but if the blood pressure be kept at as low an ebb as is compatible with life, and no sudden strain be thrown on the heart the endocarditis may be prevented in numerous cases, and when it does occur the cure may be thus hastened or the ulterior effects may be very much mitigated. To keep the blood pressure low lime salts should be eliminated from the diet, decalcifying agents should be used, the skin and bowels should be kept freely acting, and of course the rheumatism should be treated. The rest in bed should be continued for a lengthened period—at any rate, until convalescence is well established—but there is no object in continuing it for an indefinite period, as, when the patient is feeling quite well, he is apt to chafe under the restrictions, and the heart is not undergoing the necessary training to fit it for the increased work of the future. The return to active exercise should be a very gradual process, and it is well at first to have the systemic muscles subjected to passive exercise, resisted movements, massage, and, perhaps, the Aix douche; respiratory exercises are useful aids to the right side of the heart. Moderate exercise has only a slight effect in raising the blood pressure, and it afterwards lowers it by increasing the circulation in the muscle. So when the acute stage is passed a gradual training of the systemic and cardiac muscles is an advantage. In going upstairs or making an ascent no doubt the work of the heart is increased, but the chief work has to be performed by the systemic muscles, and as there is a great demand for oxidation the chief stress is thrown on the right side of the heart, hence the necessity for a little preliminary training with respiratory exercises.

The heart mischief following diphtheria, and to a less extent after typhoid fever, is myocardial rather than endocardial. In both these affections the blood pressure is very low, and hence the valves are not subjected to any great stress. In diphtheria the heart's action may be slow when the myocardium is much involved, or it may be short, quick, and frequent when there is neuritis affecting the pneumogastriacs. In both these classes the heart may be much dilated, and in such cases cardiac tonics, more especially the lime salts, are demanded. In severe cases of typhoid fever the right side of the heart is very apt to become dilated, but owing to the usual large supply of milk in this disease the lime salts are not, as a rule, deficient, and this, I think, may account for the fact that dilatation of the heart is much less common than it is in diphtheria. The injudicious supply of milk after the necessity for its use has passed may also, to some extent, explain the fact that sclerotic changes in the blood vessels are not at all uncommon after typhoid fever.

Cardiac paralysis with great dilatation of the heart is a marked feature in muscarine poisoning. In scarlet fever there may be myocarditis with dilatation of the heart; but as a rule, when heart mischief occurs in this disease, it is endocardial and is associated with rheumatism or septic infection. In influenza there is often a disturbance in the innervation of the heart, and probably often a neuritis affecting the pneumogastric and cardiac nerves. In whooping-cough the right side is chiefly affected from

mechanical causes; cardiac tonics in this case should be combined with atropine.

Infective endocarditis may affect either side of the heart, and as a rule the organisms find a nidus in some old damaged valve; but this is not necessarily the case, and I have seen the infective patch on the right side of the septum-ventriculorum. If possible the pathogenic organism should be isolated and a vaccine prepared. In such cases embolic lesions are very common, and thrombosis may occur, though this is more frequent in old, degenerate vessels; in these cases the tendency to blood clotting should be lessened by the free administration of citrate of sodium, unless there be a tendency to petechial hæmorrhages, in which case lime salts should be administered.

In shock the blood pressure should be raised by saline injections and by small and repeated doses of adrenalin injected into the veins. Dr. Blair Bell has recently shown the great value of pituitary gland in such cases. In syncope the patient should be suspended by the feet, or at least the head should be lowered and the lower part of the body raised, so as to keep the brain supplied with blood and to raise the diastolic tension in the right side of the heart. Heat relaxes the peripheral vessels and lowers the blood pressure, while cold has the opposite effect; both agents can be used in treatment.

EXERCISE.

In the *Liverpool Medico-Chirurgical Journal*, 1888, in an article on the Oertel system, I dealt very fully with the question of exercise in the treatment of diseases of the heart, and, as I have in no way altered my views on this subject since, some of the conclusions at which I arrived may be here appropriately stated. I showed that the treatment was not new, except in the extreme rigour of its details and in the wide field of utility claimed for it by Dr. Oertel. Sir Dominic Corrigan, in his classic paper on Aortic Regurgitation, in the *Edinburgh Medical Journal*, 1832, recommended in this disease

a generous and sufficient diet of animal and vegetable food; at the same time, that an abstinence from those beverages, such as malt liquors, which increase much the mass of the fluids, should be enjoined. It is not at all necessary that the patient should be prohibited from attending to his business or profession, provided that he do not devote to it so much attention as to produce debility.

Dr. Stokes described his method of treating fatty degeneration of the heart as follows:—

1. We must train the patient gradually, but steadily, to the giving up of all luxurious habits. He must adopt early hours, and pursue a system of graduated muscular exercise; and it will often happen that, after perseverance in this system, the patient will be enabled to take an amount of exercise with pleasure and advantage which at first was totally impossible, owing to the difficulty of breathing which followed exertion. The treatment by muscular exercise is obviously more proper in younger persons than in those advanced in life. The symptoms of debility of the heart are often removable by a regulated course of gymnastics, or by pedestrian exercise, even in mountainous countries such as Switzerland or the Highlands of Scotland or Ireland. We may often observe in such persons the occurrence of what is commonly known as "getting the second wind," that is to say, during the first period of the day the patient suffers from dyspnoea and palpitation to an extreme degree, but by persevering, without over-exertion or after a short rest, he can finish his day's work, and even ascend high mountains with facility. In those advanced in life, as has been remarked, the frequent complications, with atheromatous disease of the aorta and affections of the liver and lungs, must make us more cautious in recommending the course now specified.

2. We should advise the use of such a régime as will tend to nourish without increasing the bulk of the system, and especially the growth of fat. The patient may use fresh meat of any kind freely, but should avoid taking an over-quantity at any particular meal. He should abstain from all articles of food which are oleaginous, and probably also the white meats. He must be forbidden the use of soups or much milk, and should partake of vegetables sparingly. His use of beer should also be as sparing as possible. The best drink would be water, with or without a little brandy or wine, but soda water or any alkaline drinks must be inhibited, and he should accustom himself to the daily use of the cold shower bath, followed by strong friction over the whole body.

3. We can do little in this disease by mere medicines, but great attention should be paid to preserve a free state of the bowels, and from time to time the patient may use a cathartic, followed by a warm and tonic cathartic. In young patients, who approach to the anæmic state, the preparations of iron, cautiously exhibited, will be found useful.

But in the confirmed cases of persons advanced in life, specially where the patients have never exceeded in the use

of alcohol, and, above all, where the pulse is slow, with a tendency to faintness or to attacks of pseudo-apoplexy, our great reliance must be in the free use of wine or brandy, for by such a proceeding alone can we hope to preserve or prolong the patient's life. Long fasting must be inhibited, and all fatigue or mental annoyance avoided. Such persons should always have some diffusible stimulant at hand to which they may have recourse on any appearance of syncope, or of the cerebral sensations premonitory of an attack. They should be much in the open air, and, if possible, reside in a locality which combines the bracing effects of mountain and sea air; and as it is above all things necessary that their attention should be diverted from the state of the heart, the routine and too often mistaken treatment of cardiac disease must be absolutely avoided.

This advice of Dr. Stokes is, on the whole, very sound, though I cannot admit that the free exhibition of alcohol which he recommends is ever necessary. His views afford a wonderfully hopeful contrast to the following *laissez-faire* advice culled from the most recent work on diseases of the heart:

In treating cardio-sclerosis it should always be borne in mind that the condition is progressive and we cannot stay it. It usually proceeds very slowly, so that a man may show signs of arterial degeneration and irregularity of the heart from the age of 50 to 60 years, but may live in fair health for twenty years afterwards, ending his days without any marked failure of the heart. The early stages are generally recognized in the examination of the patient for some other condition, when too distinctive changes may be found in the thickened arteries, high blood-pressure, and the occasional occurrence of an extra systole. Medical men often attempt to combat these signs by some treatment more or less energetic, and as many people are frightened by the evidences of advancing years they readily comply with the proposals that are supposed to put back the hands of time; hence the great variety of drugs, methods, and modes of life we find current.

Personally I entertain very hopeful views on the prevention and treatment of cardio-sclerotic changes, and I shall have to speak of the latter part of this subject later on; we are here not much more than considering the prevention of those degenerations of which Stokes outlined the treatment. Most practical physicians recommend moderately active exercise for cases of heart disease which are fitted for such. It is only the inexperienced who frighten their patients with the danger of sudden death. Of course, no case of heart disease must be looked upon lightly, or treated in the *laissez-faire* principle; its nature, prognosis, and treatment must be carefully studied, and our directions to the patient must be clear and intelligible. In dealing with a serious lesion we must not make the patient think that it is a matter of no importance, but rather impress him with the necessity of attending to our instructions. If medical men would generally adhere to this rule I am convinced there would be fewer sudden deaths. I have often heard "the fear of frightening the patient" given as a reason for trying to avoid or delay a consultation, but I have never yet met a patient who was frightened by his medical attendant taking an intelligent interest in his case, or wishing to share the responsibility.

Chronic heart lesions of all kinds are extremely amenable to treatment, and exercise which implies both physical and vital considerations is of great importance.

Functional activity is necessary for the well-being and healthy action of every part of the body, no less for muscular structure than for anything else. No doubt the heart has functional activity under all circumstances, but it is an activity which is frequently interfered with. Nothing leads more readily to arterial degenerative changes than a life of luxury and indolence, with the retention of effete materials in the blood. A life of activity, which leads to the oxidation of these waste products and accelerates their removal from the blood, rather tends to lessen the work of the heart by relieving the peripheral resistance. But, if the exercise be excessive, there is a demand for increased work on the part of the heart, which leads to hypertrophy of that organ as well as of the muscles generally. In the first case, by the retention of effete materials with the production of gout or granular kidney, you raise the arterial tension and increase the work of the heart, which leads to cardiac hypertrophy. In the second, the heart's energy is called forth, and the blood pressure is raised from a central cause. But however this undue hypertrophy is induced, it is eventually followed by degenerative changes. It is not your athlete or your hard-worked labourer, any more than your gouty

or kidney patient, who always lives the longest. You do not want to implant a "bullock's heart" in the human chest if you can help it; such compensation may be, and no doubt often is, necessary, but it is the lesser of two evils, and is certain, sooner or later, to work mischief.

I can strongly recommend to your consideration Dr. Oertel's work,² also my article on the same subject in the *Liverpool Medico-Chirurgical Journal*, July, 1888. The Oertel treatment was both vigorous and rigorous, and where there was no advanced degenerative changes in the cardiac muscle proved highly beneficial. Dr. Oertel says:

The immediate causes which induce these disorders lie either in the pumping apparatus itself, in the heart muscle, in its weak contractions and insufficient propulsive power, in imperfect closure of its valves and narrowing of its orifices, or else in one or the other tubular system, when, from restriction of its space, it can no longer take up the quantity of fluid that it should. Such causes are *weakness of the heart muscle, fatty heart, general obesity, and valvular failure of the left heart (mitral or aortic)*. To these may be added *derangement of the pulmonary circulation from emphysema, chronic interstitial pneumonia and bronchiectasis, various curvatures of the spine (scoliosis, kyphosis), and pressure of pleuritic exudations and tumours, either developing within the thorax or invading it from without*.

His theoretical indications for the restoration of the hydrostatic balance which is deranged in cases of cardiac failure arising in all forms of heart disease are:

Diminution of the blood volume, with increase of its albumen and general improvement; reduction of the cardiac fat and strengthening of the cardiac muscle; equalization of the arterial and venous systems; unloading of the kidneys and removal of their chronic hyperæmia and inflammation; unloading of the pulmonary vessels (checking the hyperplasia of the interstitial connective tissue, reducing the oedatæ alveolar capillary network, and increasing the breathing space); finally, removal of the fat deposited in the subcutaneous tissue and in the thoracic and abdominal cavities, and overcoming the tendency to excessive fat formation generally.

He effects his object by increasing the watery excretions and limiting the supply of fluid, so that the amount taken into the system shall be rather less than that excreted, and consequently the excess accumulated in the body will be drawn upon and gradually got rid of. For the removal of the water he depends chiefly on the lungs and skin, which he stimulates to active excretion by the hot-air bath, and especially by mountain climbing. He reduces to a minimum both the drink and the fluid portion of the food, while he gives a diet rich in proteins, so as to make up for the continued loss by albuminuria, and to facilitate the rapid combustion of the stored-up fat. When dehydration has taken place to the necessary extent, and the hydrostatic balance is restored, then this condition is to be maintained by long daily walks, and a limitation of the fluids taken to the minimum necessary for tissue changes. The reduction of the water improves the consistency of the blood and relatively increases its solids, and it is also improved by the highly albuminous diet. The unloading of the pulmonary vessels and the expansion of the lungs attained by mountain climbing favours the distension of previously collapsed air cells, and encourages the oxidation of the blood. The strengthening of the cardiac muscles and the reduction of its infiltrated fat are effected by similar agencies.

He deals very exhaustively with the methods of fat reduction, as obesity is a frequent source of circulatory derangement, especially when there is an accumulation of fat upon the heart impeding its functions. When the obesity is merely plethoric, without any circulatory disturbances, it is sufficient to put the patient on a prescribed diet, and order him to lead a life of activity and hard work; but where there is also derangement of the circulation, means to restore the hydrostatic balance and improve the cardiac nutrition must be adopted.

His diet for reducing fat, unlike the Harvey-Banting and Epstein methods, consists of limitations rather than exclusions in the supply, and he prefers carbohydrates to fats. He shows that work, so long as it is not so severe as to give rise to dyspnoea, does not increase the amount of albumen destruction, but, on the other hand, increased muscular function leads to hypertrophy, with consequent storing up of albumen in the muscular elements, and so there is a demand for an increased supply. In contrast to albumen destruction, fat destruction is considerably increased by work. Personally I should take very kindly

to one of his prescriptions: "Two or three times a year long, mountainous tours must be made, according to the patient's capacity for work, which must be neither over nor under-valued." Whatever one may think of the practical value of the Oertel treatment, we must admire the boldness of conception, and the indefatigable energy with which it was carried out, together with the enormous number of scientific observations which Dr. Oertel has placed on record. The first patient, Dr. N., undertook most arduous mountain ascents, frequently climbing mountains from 1,000 to 1,500 metres above the valley level in about the same time as these feats are accomplished by healthy individuals. The difficulty of this task may be easily surmised when it is stated that his vital capacity only ranged from 64.0 to 86.4 cub. in.

His pulse, once very frequent, 112 to 120 per minute, or sinking to 54 or even 48, irregular, jerky, and small, was now rhythmic, slow, regular (80 to 94 per minute), full, powerful and not easily compressed. Before treatment the patient's circumference was 49.6 in. and his weight 171.6 lb.; these figures were lowered after a year's treatment to 37 in. and 116.6 lb. The fat of the subcutaneous tissue was everywhere reduced to an insignificant layer, and the skin could be drawn in thin folds over the strongly-developed muscles, which felt hard and firm on each contraction.

Personally I do not care for any routine system, because you are apt to lose the individual in generalities, and in my opinion you should always treat the individual rather than his disease. It is here not a question of failing to see the wood for the trees, but of neglecting the proper care necessary for the individual tree. There is no doubt in my mind of the great value of exercise in heart disease, but it has its limitations, and there is no better training for the respiratory and cardiac systems than that of mountain-climbing. Golf, curling, and bowls are excellent restoratives, if not accompanied by too much Scotch whisky, for old gentlemen with not much reserve energy; but if you wish to improve the respiration and strengthen the right side of the heart take to mountain-climbing. In this form of exercise the precautions which I wish to emphasize are that the training must be gradual. You must produce no marked dyspnoea, and if the vital capacity be not up to the normal or there be any degenerative changes in the cardiac muscle, you had better not get higher than 4,000 or 5,000 ft. above the sea level. Cases with defective pulmonary capacity and an overloaded venous system are predisposed to dilatation of the right side of the heart. If, therefore, any one sends such patients to exercise in climbing steep mountain ascents without preliminary training, he may find, when too late, that his advice has been followed by irremediable dilatation of the right ventricle. Patients with degenerative changes in the cardiac muscle, which may even not have been previously detected, are very liable to fatal congestion of the lungs when suddenly transported to very high altitudes, even though there has been no exertion.

In a large proportion of cases of heart disease there is no marked disturbance in the hydrostatic balance until after failure of compensation—which may have been perfect for many years—subsequent to degenerative changes. The heart-muscle is not then in a condition to respond to any graduated exercises, and requires to have its work lessened to a minimum by complete repose of the body in bed. In some cases the nutrition of the body, and consequently of the heart, may be improved by massage, but there must be no acute straining of the exhausted ventricular walls by active exercise. In some cases of fatty infiltration there is no proper compensation; the enlargement of the heart is due to fat and not to muscle. In such cases we must get rid of the fat by increased oxidation, and improve the nutrition and effective force of the cardiac muscle by a highly nitrogenous diet and a small supply of liquids.

When a patient has got heart disease it is our duty to adopt such means as will maintain compensation for the longest possible period of time. This will not always, or even generally, be effected by trying to make him a powerfully athletic man. The compensation must be sufficient but not excessive, and there is no advantage to be gained by unduly testing its sufficiency, or placing the patient under conditions which would tend to its excessive development. The patient must be taught to live metaphorically, and in many cases physically, at a low level. He must be content with healthy existence

rather than active life. His life need not be that of the sloth or dullard, but it will not always be well to test to their extreme limits his physical or mental capacity.

The effects of mountain-climbing may be to a large extent summed up in the word "oxidation." Your obese man does not oxidize all the carbonaceous matter which he takes in. He may at first have normal oxidation, but the food supply is excessive. When the heart becomes implicated the oxidation lessens, and so the disproportion between the "input and output" increases. Your portly dame may owe her excessive corpulence to tight lacing in youth. With advancing years, when her marketable value has been determined or her matrimonial chances have lapsed, she removes the restrictions on diet which she formerly exercised, and then her small thoracic capacity is not able to supply sufficient oxygen to burn off all the hydrocarbons and carbohydrates taken in. In mitral stenosis and mitral regurgitation there are mechanical impediments to the onward course of the circulation, hence the tissues are not supplied with a sufficient amount of oxygen. The lung capacity may be at first perfect, but from damming back of the blood pulmonary changes gradually take place, and from the diminished vital capacity oxidation is further interfered with; and as imperfectly oxidized blood will not, under any circumstances, flow freely through the lungs, the task of the right ventricle is greatly enhanced. The same may be said where there is compression or destruction of lung tissue, as in scoliosis, kyphosis, great pleural effusion, emphysema, and intrathoracic growths. In all these cases great good may be effected by diminishing the supply of fluid, thus lessening the amount of blood in circulation, increasing its density, and relatively augmenting its oxidizable material. Breathing condensed air will also increase the amount of oxygen, but the same can scarcely be said of the atmosphere at high altitudes, where its rarity is not counterbalanced by any equivalent expansion of the chest. In obesity with fatty infiltration, where the thoracic capacity is intact, the respiratory activity induced by mountain-climbing will effect the necessary oxidation when the fluid is diminished. In anaemia the haemoglobin is defective, and hence the oxygen-carrying power of the blood is diminished, and there is a tendency to the deposition of fat. In the majority of these cases there is a great quantity of fluid in the system, with high arterial tension. These conditions can be relieved by diminishing the supply of fluid, and hastening its excretion by mountain-climbing. The enlarged flabby and fatty heart is frequently not able to respond to this demand for extra work. The early treatment of profound anaemia can usually be best carried out in bed, while we may reserve the mountain-climbing for the completion of the cure.

As to the details of treatment, we must first consider the limitation in the amount of fluid imbibed. This is an important element in the treatment of all forms of heart disease. Every drop of water, whether in liquids or solids, which is taken into the stomach, with the exception of that part which passes away in the faeces, must pass through the right side of the heart before it is excreted. Thus any excessive amount of fluid must increase the work of the heart, lessen the density of the blood, and relatively diminish its oxygen-carrying power. When the circulation is vigorous, and especially if there be inordinate high arterial tension, it is remarkable what an enormous amount of fluid can be consumed without any marked interference with the density of the blood, the excretion takes place almost as rapidly as the absorption from the stomach and bowels, and there is no retention of the fluid in the system. But even in health these two processes do not always go on *pari passu*, and there is a considerable retention of fluid in the veins, if not also in the tissues. The veins are capable of holding all the blood in the body, and so at any time a considerable augmentation of their contents may take place without this condition being noticed, or any increased transudation taking place into the tissues. The excretion of urine frequently varies from day to day, irrespective of the amount of fluid taken in, and anything which raises the arterial tension, such as hard mental work, will act as a powerful diuretic, without any additional fluid supply. To see what an enormous amount of fluid can be disposed of in health, witness the typical German at his lager beer. When these men keep on soaking after the central pump begins to fail, Oertel's

treatment will prove a valuable means of saving them from drowning in their own juice. Witness also the prescriptions of some physicians at mineral-water resorts to see the amount of fluid which may be consumed in cases of comparative health. These patients are treated as dirty sewers which require to be thoroughly flushed. When, however, a patient with a weak heart is exposed to this routine treatment the effects are not encouraging, though it is generally discovered that "the case is not a suitable one for the cure" before irremediable mischief has been done.

When we have to deal with a feeble heart, or when from any cause there is obstruction to the pulmonary circulation, then absorption takes place much more readily than the fluid can pass into the arterial system, and so there is a tendency to gradually-increasing disturbance in the hydrostatic balance. In these cases diuretics are comparatively useless: the difficulty is in getting the blood as far as the left ventricle, not in getting it through the kidneys. We keep the supply below the amount excreted by all channels, so as to restore the hydrostatic balance and maintain that condition when established. Whatever be the amount excreted, if the supply from all sources be still less dehydration of the body must take place, and the greater the disparity between these amounts the more rapid the dehydration. In cases of marked dropsy I have often seen the urine quickly increase when the supply of fluids was cut off. I have even kept such patients without any water, except that contained in a dry diet, for even a week with the most beneficial results. If there be any danger of the depletion of the veins going on much more rapidly than the absorption of the fluid from the interstices of the tissues, this can be obviated by the gentle pressure of an elastic bandage applied to the oedematous lower extremities. All watery excretions, with the exception of the exhalations from the lungs, takes place from the arterial rather than the venous blood. The water of the urine is excreted from the arterial capillaries in the Malpighian corpuscles. In purgation the water is excreted from the intestinal capillaries, and perhaps also from the small venous radicles. The sweat is excreted from the capillaries supplying the sweat glands and ducts. In general anasarca free perspiration is often difficult to induce, as the sweat glands and ducts are compressed and the blood driven away from the surface; before this effused fluid can be got rid of by sweating, it has to be absorbed into the veins, pass through the pulmonary and systemic circulations, until it reaches the capillaries supplying the sweat glands. From the foregoing considerations it follows that, when there is a disturbance in the hydrostatic balance, with accumulation of blood in the veins, any method to reduce the excess of fluid in the veins, except that of increasing the pulmonary exhalations and diminishing the fluid supply, must act indirectly. Even phlebotomy drains the blood in the course of the circulation directly from the arterial system, and only indirectly depletes the main veins and pulmonary circuit. Therefore, in all cases of disturbed hydrostatic balance our first object should be to diminish the fluid supply, and allow the excess to be disposed of through the ordinary channels. You should give a salt-free diet, as sodium chloride has a high osmotic equivalent, and holds the fluid in the tissues.

The dehydration should be carried sufficiently, but not too far. The amount of dehydration depends on the difference between the total supply of water and the amount excreted.

Pulmonary Exhalations.—Increased watery exhalations from the lungs primarily depletes the venous system. In order to increase this excretion the atmosphere breathed must be *warm and dry*, so as to be capable of freely absorbing moisture. The Turkish bath provides us with this kind of atmosphere in a prominent degree; but, on the other hand, the great heat of the Turkish bath does not favour oxidation or increase the respiratory activity, while at the same time it has an even greater effect in increasing the watery excretion of the skin than that of the lungs. Therefore the arterial system is depleted to a greater extent than the veins; this dehydration of the tissues, increases thirst, and the fluid supplied tends to maintain the previous condition of the veins. The depletion of the venous system through exhalation of the lungs is best carried out in a *warm dry* atmosphere, of a temperature

say, between 60° and 70° F., under such conditions of active exercise—say, mountain-climbing—as will augment the respiratory activity and increase oxidation.

Sweating.—Increased watery discharge from the skin depletes the capillaries, and through them the tissues; therefore its value will vary much in different cases. In general obesity with fatty infiltration of the heart, when there is a sudden condition of the tissues and no mechanical obstruction to the passage of blood through the lungs, it will prove of great service. In the big, dilated hearts of beer drinkers it is valuable, but cardiac tonics should also be employed. The Turkish bath may be used, but sweating is best induced by mountain climbing, which improves respiration and oxidation, and the exercise hastens on the circulation in the veins. Sweating can be recommended in all cases where there is a free pulmonary circulation, such as in cases of general obesity, fatty infiltration of the heart, and weakness of the myocardium, but it is of very little value where there is pulmonic obstruction, such as in cases of mitral stenosis and incompetency, emphysema, intrathoracic tumours, disease of the pulmonic or tricuspid valve, etc. Its value in the various forms of dropsy will be found fully discussed in my paper on The Pathology and Treatment of Dropsy, in the *Liverpool Medico-Chirurgical Journal*, July, 1886.

Purgation.—Profuse watery evacuations from the bowels is too depressing a method of treatment to be commended; moreover, it primarily depletes the arterial system, and any great and sudden lowering of arterial pressure in cases of weak heart might have a disastrous consequence.

Diuretics.—The renal excretion in these cases is very variable. In weak or fatty hearts it is scanty, owing to the feeble propulsive power of the central pump, with diminished velocity of the blood; in these cases it is useful to increase the discharge by such nerve and vascular tonics as caffeine and strychnine. In aortic and mitral stenosis and in aortic incompetency the arterial tension in the early stages is usually high, and the urinary excretion free; in the later stages, where there is failure in compensation, digitalis and squills may be given for short periods. In mitral regurgitation digitalis is, as a rule, the best diuretic. In affections of the pulmonic and tricuspid valves cardiac tonics are of much less value than in diseases of the left side of the heart. Here their use must be supplemented by great diminution in the amount of fluid supplied, and by *rest in bed*. Where the obstruction to the pulmonary circulation lies in the lungs, such as in emphysema, diuretics are comparatively valueless, and perhaps the best in these cases are those that act directly on the kidney, such as the caffeine and theobromine series. The presence of albuminuria, which is so common in all cases of cardiac failure, depends on the increased static pressure and diminished velocity of the blood in the Malpighian corpuscles. It is an indication of the state of the circulation rather than the condition of the kidneys, and need cause no apprehension. It is not the albumen which one excretes, but the effete material which he retains in his system, that works the mischief. Any treatment which restores the hydrostatic balance will lessen or cure the albuminuria.

Baths.—All kinds of baths tend to keep the skin clean and help to improve the peripheral circulation; warm baths lower and cold baths raise the blood pressure, at least temporarily. The electric light bath, especially if followed by massage or a douche, has a beneficial effect on the circulation in the periphery. The carbonic acid bath has a gentle stimulating effect; the Nauheim baths, with passive and active exercises, are often useful preliminary training for more healthful out-door work. These baths are not suited for cases with pulmonary obstruction. The Turkish bath, followed by massage and a limitation in the amount of fluid imbibed, is often beneficial where there is no advanced degenerative changes in the blood vessels.

MEDICINAL.

I do not intend to say much about drugs, because I think such remedies should only be used when necessary and always under strict medical supervision. Unfortunately for the public they have taken to drugging themselves with all manner of noxious tablets, and I know that an enormous amount of mischief is caused by the indiscriminate use of cardiac tonics. The con-

tinned high-arterial tension which is thus long maintained often works irreparable mischief in the aorta. It is better for a jaded horse to lighten his load than apply the whip, so remedies which lessen the work of the heart are often more effective than cardiac tonics. When the balance between the two sides of the heart is effectively maintained, drugs are, as a rule, unnecessary, except to regulate the blood pressure, and when this is high, decalcifying agents and moderate cathartics answer best. When there is cardiac failure, tonics such as digitalis, squills, strophanthus, caffeine, strychnine, and the lime salts must be used, as soon as compensation is restored their use should be discontinued. If there be any tendency to thrombosis or embolism, decalcifying agents, such as phosphoric and citric acids and their soluble salts, should be employed. In cases of cardiac thrombosis and pulmonic embolism where the symptoms are very urgent strong ammonia should be freely used; a mixture of 5 minims each of liquor ammoniac fort. and spiritus chloroformi in a wineglassful of barley water every hour or half-hour is an effective remedy. In mitral stenosis you not infrequently get a free hæmoptysis, which in this case is the best form of blood-letting, and should not be too quickly checked. In 1886 I condemned the use of all astringents in such cases, and strongly advocated the employment of nitroglycerine and atropine. It is rather amusing to me to see the rediscovery of this treatment recently in the medical journals. In all spasmodic affections, such as angina pectoris, the best remedies are nitroglycerine, morphine, atropine, nitrite of amyl, iodide of ethyl, and other preparations of iodine. When the blood pressure is very high, there are a whole host of remedies at our command in addition to those which I have mentioned for the treatment of spasmodic or painful affections, but we may specially specify decalcifying agents, the benzoates, the hippurates, iodine, and thyroid.

The Lime Salts.—So far as we at present know, the presence of free calcium ions in the blood and tissues is necessary for effective muscular contraction, and now that my friend, Dr. Blair Bell, has given us an excellent method for estimating the free calcium in the blood there is no reason for any one being ignorant on the subject. The calcium ions increase the force of the muscular contraction but diminish muscular irritability and (according to Loeb) inhibit the rhythmical contraction of muscle fibres, which he thinks does not depend on lessened excitability, but on some chemical combination of the calcium ions in the muscle which renders its rhythmical contraction more difficult or impossible. I am still of opinion that the calcium ions lessen irritability of the heart muscle, and Blair Bell has shown that when a solution of calcium chloride was injected into the veins of a rabbit the rhythmical contraction continued, the amplitude of the contractions increased but their frequency diminished, and when a poisonous dose was used the heart finally ceased in systole. In many febrile affections the calcium salts are readily thrown out of the blood, hence a frequently renewed supply is demanded; but unfortunately, long after the demand is satisfied the supply continues, owing to the indiscriminate use of milk in all the ills to which flesh is heir. Nowadays milk is not confined to babes and sucklings, but has been extended to those of riper years. This inordinate supply of lime salts increases the viscosity of the blood, raises the blood pressure, hastens the formation of scar tissue, and leads to degenerative changes in the vessels and heart. When there is an excess of calcium ions in the blood, the cardiac contractions are apt to become infrequent, slow, and effective, and owing to the greater muscularity of the left ventricle its irritability becomes less than that of the right, and the rhythmicity of the latter being greater it tends to act in advance; hence we get irregularities and intermissions. A similar inhibition is also often induced by digitalis, which seems not only to inhibit the action of the heart but also to disturb the balance of blood pressure in the two sides. When the pulse becomes very slow, as in Stokes-Adams disease, it is well not only to cut off the lime salts and use decalcifying agents, but you should also use such ions as stimulate rhythmical contraction, such as sodium, chlorine, and iodine with thyroid; strychnine is also valuable.

Alcohol.—There is no condition of the heart in which alcohol is beneficial, except in spasmodic and painful

affections such as angina pectoris, and even in such cases nitroglycerine, morphine, and atropine are better and more easily regulated remedies. Alcohol is a proto-plasmic poison, and under no circumstances can it strengthen the cardiac muscle. It lowers the arterial and raises the venous pressure, and increases the diastolic tension within the heart. In this way it acts as a cardiac stimulant, but as it has a paralysing effect on the cardiac muscle there is a loss of tone with tendency to dilatation of the heart; hence the large, flabby, fatty hearts of beer-drinkers, and the great retention of fluid in their vessels and tissues. Tobacco is a nervine sedative and cardiac depressant. Cases of heart disease do better without it.

CONCLUSION.

This address has already assumed such lengthy proportions that I must defer the treatment of that large class of cases of chronic degenerative lesions of the vessels, heart, and its valves until some future occasion. I have told you that a modern authority says that "cardio-sclerosis is progressive, and we cannot stay it," so I presume the other branch of my subject can afford to wait. On the other hand, I am inclined to think that if you follow in the lines which I have already laid down, you may not merely stay the progress of these degenerative lesions, but, what is infinitely more important, you may often prevent their occurrence.

A CASE OF HEART-BLOCK, WITH FIBROUS DEGENERATION AND PARTIAL OBLITERATION OF THE BUNDLE OF HIS.

By BYROM BRAMWELL, M.D., F.R.C.P.E.,

SENIOR ORDINARY PHYSICIAN, EDINBURGH ROYAL INFIRMARY.

THE following are the notes of an interesting case of heart-block in which the auriculo-ventricular bundle of His was almost completely degenerated. The case is unique, inasmuch as a complete heart-block has not, so far as I know, been previously observed as the result of rheumatic fever; cases of slight heart-block after rheumatism have been described (see, for instance, Cases XVIII and XXII, pp. 324 and 339, Mackenzie's *Diseases of the Heart*).

Dr. James Mackenzie has kindly read over the case, and given me his opinion with regard to the tracings. Unfortunately the tracings which were taken of the radial pulse and some of the tracings from the neck, showing the venous and carotid pulses, have been lost.

A Case of Heart-block: very slow pulse; fibrous degeneration of the auriculo-ventricular bundle of His; calcareous nodule situated at the right end of the attachment of the anterior mitral flap extending into the septum, obliterating almost completely obliterating the bundle towards its auricular extremity.

Clinical History.

J. F., aged 29, married, formerly a worker on the railway, was admitted to the Edinburgh Royal Infirmary on April 14th, 1907, complaining of pain in the joints, chest, and region of the heart.

Previous History.

The patient has had six attacks of rheumatic fever, at the ages of 15, 17, 20, 22, 23, and 26 respectively; since the first attack of rheumatic fever, when the heart is said to have been affected, he has been short of breath on exertion.

Three years ago, when shunting on the Caledonian Railway, he fell in front of a train; his left hand was crushed, and the left arm had to be amputated. He has not worked since this date.

The present attack of rheumatic fever commenced fourteen days ago; up to that time he was feeling quite well.

Unimportant.

Family History.

Social Conditions and Surroundings.

Fairly good. Formerly a heavy smoker, has smoked much less lately; a teetotaler.

Condition on Admission.

Almost all the joints are swollen and painful. Temperature on the morning of admission 101.8°, on the evening of admission 103°; pulse 106; respirations 24.

Cardiac pulsation seen over an extensive area; apex beat in the sixth left interspace, 2½ in. below and 1 in. outside the mammary line (4 in. from the sternum); a long, loud, harsh systolic murmur and a soft diastolic murmur heard in the aortic area; a long systolic murmur in the mitral area. Radial pulse 106; tension medium; arterial coats not thickened. Lungs normal. Tongue furred; slight constipation; liver not enlarged. Complaints of some headache but sleeps fairly well. Urine: specific gravity 1014; no albumen; a heavy deposit of urates. The red blood corpuscles number 3,920,000, the haemoglobin equals 70 per cent., and the white corpuscles number 7,400.

Treatment.

Sodium salicylate 20 grains, three times daily; milk diet.

Progress.

Rapid improvement; disappearance of joint pains.

On April 7th the temperature was normal and the patient was feeling very well.

On April 10th the patient woke at 2 a.m. with severe pain over the region of the heart; at 6 a.m., while washing himself, he suddenly became weak and breathless. On examination the pulse was found to be beating at the rate of 30 per minute. The patient vomited after breakfast. When seen by me at 10.30 a.m. the radial pulse numbered 26 per minute; the temperature was 99.2°. The cardiac ventricles were contracting at the rate of 26 per minute. The right side of the neck looked full (apparently due to distension of the right internal jugular vein); the right external jugular vein was distended and distinctly pulsating; the venous pulse on the right side of the neck numbered from 80 to 90 beats per minute; the pulsation of the right common carotid artery was feeble and numbered 26 per minute. The right radial pulse was small and feeble. The apex beat of the heart was in the sixth interspace, 2½ in. below and 1 in. external to the nipple line. Pulsation could also be seen and felt in the fourth and fifth left interspaces; the pulsation in the fourth left interspace seemed to occur a little later than the apex beat. A very long and loud systolic murmur was audible in all the cardiac areas; it was perhaps a little louder in the tricuspid area than elsewhere. This systolic murmur was immediately followed by a short murmur and then (that is, after the short murmur) by a sound which seemed to be the second sound. I was not able at the time to interpret the meaning of the second (? diastolic) murmur and of the sound (? second sound) which followed it. I simply state the facts as I thought I heard them—the description was dictated to my house-physician at the bedside.

The pulse waves were equal and measured 2½ mm. in diameter. With each pulsation of the cardiac ventricle and slightly after it, a quick jerking movement of the head, sometimes double in time, occurred as a result of contraction of the neck muscles. This jerking of the head was a curious phenomenon which, so far as I know, has not been noted in any case of heart-block before, possibly it was due to reflex stimulation of the neck muscles through the vagus.

Some of the tracings, taken on April 10th and 11th, of the pulsation in the neck and heart's impulse are reproduced in Figs. 1 to 7.

Fig. 1, which is a tracing from the neck, shows both the venous pulse due to contraction of the right auricle and the carotid pulse. The small waves (a) in the tracing are chiefly

Fig. 1.—Tracing of the movements in the neck due to the carotid and auricular pulses. The small waves (a) are due to the auricle, and the large waves (c) are due to the carotid—an auricular wave in the jugular occurring at the same time as the carotid pulse (see diagram, Fig. 2).

auricular and are superimposed on the carotid pulse when it appears. The big waves are a combination of the auricular and ventricular (carotid) contractions (c + a). The other neck tracings also show the auricular waves. Fig. 2 is a diagram showing more clearly the independent rhythm of the auricle

Fig. 2.—Diagram representing the movement shown in Fig. 1. The perpendicular lines in the upper space represent the systoles of the auricle (A) as shown by the waves a; those in the lower space represent the systoles of the ventricle (V) as shown by the carotid beats. The relation of the V to the A is constantly varying, showing therefore that the systole of the ventricle occurs independently of the stimulus from the auricle.

and ventricle. Fig. 3 is a tracing from the left ventricle; it shows the rise characteristic of the ventricular systole. The small waves in this tracing are due to contraction of the left auricle. Fig. 4 is a tracing partly from the left ventricle (the

upstroke) and partly from the right ventricle (the fall). This tracing shows that both ventricles shared in the slow action.

In these four tracings (Figs. 1, 2, 3, and 4) there seems to be graphic evidence of the contractions of all four chambers of the heart. The small waves (a) in Fig. 1 are jugular waves, due to contraction of the right auricle; the small waves in Fig. 3 appear to be due to contraction of the left auricle; the contractions of the left ventricle are shown in Fig. 3, taken from the (left) apex beat; and the contractions of the right ventricle are shown in Fig. 4.

Fig. 3.—Tracing from the apex, showing the infrequent contractions of the left ventricle. The small waves between the large beats are due to the systole of the left auricle.

Fig. 5 appears to be wholly right ventricle and shows the inverted cardiogram in contrast with that represented in Fig. 3 from the left ventricle. Fig. 6 is, no doubt, left ventricle and shows the long pauses with auricular waves very distinct. Fig. 7 is a simultaneous tracing of the apex beat and of the pulsation in the neck; it was made on April 11th.

Fig. 4.—Taken over the right ventricle, showing a great fall during systole (the inverted cardiogram characteristic of the systole of the right ventricle); it also shows that the right ventricle participated in the infrequent action with the left ventricle.

April 11th. The patient appears to be slightly better this morning. The ventricular contractions and the radial pulse number 30 per minute. No change in the strength and character of the heart beats; a long, loud systolic and short diastolic murmur still present; the radial pulse is rather weaker. During this day the patient had several attacks of very severe angina

Fig. 5.—Tracing from the fifth left interspace, made on April 11th, 1907. This tracing appears to be wholly due to the right ventricle, and shows the inverted cardiogram in contrast to Fig. 3.

pain; he stated that he felt as if he were being crushed between two buffers. The radial pulse during the attacks of pain was almost imperceptible and somewhat irregular. The jerking movements of the head with the apex beats of the heart still continue. There has been a great deal of vomiting. Amyl nitrite inhalations, strychnine subcutaneously, and a menthol mixture were prescribed.

Fig. 6.—Tracing from the apex beat of the heart made on April 10th, 1907. This tracing appears to be due to contraction of the left ventricle, and shows the long pauses between the ventricular contractions with small auricular waves interposed.

April 12th. Much worse; very restless all day. Pulse down to 24 per minute. The pain in the heart has been very severe and distressing. Morphine has been given at frequent intervals. Towards midnight the pulse went down to 22. The vomiting has not been so bad to-day. The pupils now measure from 5 to 6 mm. in diameter. The patient is perfectly sensible.

Fig. 7.—Combined tracing from the apex beat and neck made on April 11th, 1907.

April 13th. 2 a.m. The cardiac pain was so severe that morphine had to be given on several occasions. Pulse 19; respirations 17. An interval of 8 seconds was counted between two of the cardiac beats on one occasion. The radial pulse is very irregular. The patient died at 4.30 a.m.

Post-mortem Examination.

This was made by Dr. Shennan on April 13th, 1907. Both lungs were in places attached to the chest walls by old adhesions. The pericardial sac was obliterated as the result of old

pericarditis. The exterior of the pericardium was adherent to the thoracic wall opposite the apex of the heart.

The heart was injected with formalin in order that the auriculo-ventricular bundle might be carefully dissected out.

On passing the fingers through the auricles a large calcareous mass could be felt, on the upper border of the inter-ventricular septum posteriorly, apparently measuring about 1 1/2 in. antero-posteriorly by about 1 in. vertically and about 1 1/2 in. transversely. On further examination, after fixation, this corresponded to the anterior cusp of the mitral valve, which was extremely calcareous.

There was some bronchitis and congestion of the lungs, but no consolidation. The liver was enlarged, congested, and fatty. The kidneys were large and congested, with some swelling and fatty change. The spleen was firm, large, and congested.

Subsequent Examination of the Heart.

General adhesion of the pericardium to all the cardiac cavities; hypertrophy of the ventricles; old endocarditis with calcareous deposits in the aortic and mitral valves; the anterior flap of the mitral valve markedly calcareous; some narrowing of the mitral orifice; thickening of the tricuspid with some dilatation of the orifice; pulmonary cusps slightly but uniformly thickened.

Dr. E. B. Jamieson of the Anatomical Department kindly dissected out the auriculo-ventricular bundle. His report on its condition is as follows:

The auriculo-ventricular bundle of His has apparently undergone fibrous degeneration, and the few muscular fibres remaining on the surface are very pale. A calcareous nodule situated at the right end of the attachment of the anterior mitral flap extends into the septum, invades and well nigh obliterates the bundle towards its auricular extremity.

NOTE ON THE PULSUS BIGEMINUS.

By E. E. LASLETT, M.D., B.Sc.,

HULL.

My object in publishing this note is to draw attention to a curious, and I believe hitherto undescribed, form of jugular pulse associated with the pulsus bigeminus, which in itself is not a very uncommon phenomenon.

The patient, a man aged 40, was first seen on June 27th, 1906. He had been working at his trade as a painter up to a week before. He had had heart disease to his knowledge for seven years but had never been laid up on this account. At one time he weighed 16 st., but for some months he had been losing flesh. He had been temperate as regards both alcohol and tobacco.

He suffered greatly from dyspnoea, which necessitated his being propped up in bed. He was pale and flabby, and there was considerable oedema of the legs and trunk but no ascites. The pulse was 100, regular, with a large, markedly collapsing beat, and the marked throbbing of the arteries, characteristic of aortic disease, was very noticeable, and perceived by the patient himself. The heart was enlarged to the right, and to the left to 1 in. outside the nipple line. There were double murmurs at all areas of the heart but no thrill could be felt. It was obviously a case of failure of compensation in aortic disease. Tracings taken at this time showed that the pulse was quite regular, while there was a very large auricular wave in the jugular pulse, which was otherwise normal. He was much troubled at night with cardiac asthma, and the usual drugs were tried, without any but temporary relief to this symptom. In spite of treatment by rest in bed and cardiac drugs the oedema and other symptoms of distress persisted, and he died on July 31st. For the last fortnight he was taking 5-minim doses of tincture of strophanthus with citrate of caffeine.

A week before his death his pulse took on a bigeminal character, which was continuous, and persisted until the day before he died, when it became too feeble to detect its true rhythm. The tracing of the jugular and radial pulse when this condition was present is shown in the accompanying figure, from which it will be seen that at the extra beats which are the cause of the bigeminal rhythm, the auricles contracted during the ventricular systole, and there is one large wave synchronous with the extra beat in the radial artery. The increased size of this wave is due, as Mackenzie has pointed out, to the fact that the right auricle is unable to empty itself into the contracted ventricle, and therefore a larger quantity of blood than usual is sent into the jugular veins. The unusual feature in this tracing lies in the fact that the combined wave commences distinctly beyond the middle line—that is, nearer to the post-extra-systolic auricular wave than to the pre-extra-systolic. This puzzled me so much that I sent this and another tracing of two days' earlier date to Dr. James Mackenzie, who most kindly examined them.

The figure shows the character of the jugular pulse associated with the bigeminal rhythm in the radial pulse. The appended diagram explains the nature of the events. A-s signifies auricular systoles; V-s, ventricular systoles; and A-V, the conduction between auricle and ventricle.

for me. He confirmed the existence of this peculiarity, and kindly indicated the diagram appended to the tracing, which shows very clearly the nature of the events. Mackenzie divides extra-systoles into three types—auricular, ventricular, and nodal—the ventricular including the rare form of interpolated extra-systole. He has suggested that the probable origin of the extra-stimulus lies somewhere in the remains of the primitive cardiac tube, in auricle, ventricular bundle, or auriculo-ventricular node. In the nodal extra-systole the auricles and ventricles contract together, or nearly so, and usually prematurely. It may, however, happen that the combined wave appears at the normal period of auricular contraction, and it may then be difficult to determine whether the extra-systole is of nodal or ventricular origin. In the present instance, from the regularity and persistence of the bigeminal character, and the fact that the auricular wave is always synchronous with the ventricular, it is probable that the extra-systoles are of nodal origin. Although there is no time record in the tracing, it may be taken as certain that the *a-c* interval is increased. In an earlier tracing, in which the combined wave was nearer the middle point, the *a-c* interval was less. The increase of the *a-c* interval is no doubt due to the incomplete restoration of conductivity as a result of the short period between the extra-systole and the following normal auricular beat.

I am unable to explain this peculiar rhythm. It is evident that alternate auricular contractions failed to appear at the normal period, but whether the sinus rhythm remained regular or not it is impossible to say. On the day of death the pulse became very feeble and quick, and the patient was too ill to allow of a tracing being taken. It is consequently uncertain whether the heart in the final stage became continuously irregular (nodal rhythm).

THE INEFFECTIVENESS OF CALCIUM SALTS AND OF CITRIC ACID AS USED TO MODIFY THE COAGULATION TIME OF THE BLOOD FOR THERAPEUTIC PURPOSES.

WITH A DESCRIPTION OF A MODIFICATION OF MCGOWAN'S
METHOD OF ESTIMATING THE COAGULATION
TIME OF THE BLOOD.

By T. ADDIS, M.D., M.R.C.P. EDIN.,
CARNEGIE SCHOLAR.

By means of a more accurate method than Sir A. E. Wright's, I have shown that he was mistaken in his statement that soluble calcium salts and citric acid are capable of altering the coagulation time of the blood of people in health. The fact that this initial experimental result of his cannot be confirmed is sufficient in itself to throw great doubt on his later work in this connexion. Since 1893 he has published a number of papers on the use of calcium in the treatment of hæmophilia, and of hæmorrhage in many other conditions, and also in what he terms "serous hæmorrhages"—a group of conditions said to be characterized by an abnormally long coagulation time, which could be cured when the coagulation time was reduced by the administration of soluble calcium salts. Further, citric acid was recommended as a prophylactic against thrombosis in typhoid fever. Although clinical

reports as to the value of this method of treatment have been conflicting, the general idea that the coagulation time in disease can be shortened or lengthened at will, by giving the proper dose of calcium lactate or citric acid, has never been effectively disputed, and has been very widely accepted and acted upon.

It was not possible to test the accuracy of this belief by the method of estimating the coagulation time of the blood which I have described, since it is not applicable clinically because of the presence of a greater or less degree of auto-agglutination of the red blood corpuscles in very many pathological conditions. Another method was therefore necessary, and the modification of McGowan's method, which is described below, is one which is applicable clinically, and which yields results which can be relied upon within certain limits.

In reviewing the different methods I found that the means adopted by Sabrazès and McGowan of determining the presence of a certain definite amount of coagulation is more accurate than those employed in the other methods, although it is not possible to obtain constant or comparable results with either of their methods, because in the case of the former the means of maintaining a constant temperature is not sufficient, and in the latter is wanting altogether.

McGowan believed that for clinical purposes it was superfluous to have an apparatus to maintain his glass tubes at a constant temperature, since variations of temperature between 15° C. and 20° C. did not appreciably affect the coagulation time.

This, however, as I have already shown, is very far from being the case. With my method the following coagulation times were found to correspond with the temperatures between 15.5° C. and 20.5° C.:

15.5° C., 11 min. 46 sec.;	18.5° C., 7 min. 34 sec.;
16.5° C., 10 min. 10 sec.;	19.5° C., 6 min. 2 sec.;
17.5° C., 8 min. 7 sec.;	20.5° C., 5 min. 22 sec.

The necessity of the maintenance of a constant temperature is, therefore, fully apparent. The variable results which are obtained by these and other coagulometers are said by those who use them to indicate true variations in the coagulation time of the blood, but the coagulation time is found to be constant when a more accurate method is used, and those apparent variations are really due to experimental errors, of which the most important is a deficiency in, or a total neglect of, the maintenance of a constant temperature for all observations.

Description of the Method.

McGowan's method consists in partially filling a capillary glass tube, 6 in. long and 1.5 mm. in diameter, with blood under certain precautions, sealing up one end, and at intervals of a minute breaking off a small part until a fine fibrin thread is seen on slowly drawing the fractured ends apart. The coagulation time is the time elapsing between the filling of the tube and the first appearance of fibrin.

Undoubtedly the simplest and most accurate way to keep the tubes always at the same temperature would be to use a gas regulator. But in the wards of most hospitals there is no gas, and it is absolutely necessary that the whole procedure should be carried out by the bedside of the patient. An electrical thermostat would be sufficient, but is expensive, so it was better to dispense with any mechanical regulator, and to make use of the following device.*

When a closed cylindrical vessel is placed in the centre of a similar but considerably larger vessel, and both are filled with

* The apparatus can be obtained from Paul Altman, scientific instrument maker, 56, Lottisen Strasse, Berlin, for 36 marks.

water at a temperature of 20° C., a fall in the temperature of the water in the outer cylinder shows itself before any change in the temperature of the inner cylinder can be seen. If, whenever this is observed, a little hot water be added to the outer cylinder until the water is again at 20° C., the temperature of the water in the inner cylinder may, with a little care, be kept practically constant for any time that may be desired.

When the McGowan's tubes are introduced into the inner vessel their environment has thus a constant temperature of 20° C. This was chosen as the temperature at which all observations were conducted because it is a little above the ordinary ward temperature, which generally varies from 15° C. to 20° C. Usually the ward temperature is only slightly below the temperature of the water in the apparatus, so that it is only necessary to add a little hot water every half hour or so.

The outer cylinder is made of metal and is covered with asbestos. It is 9 in. high and has a diameter of 6 in. Piercing the lid there is on one side a tube leading down almost to the floor, so that where hot water is introduced it may enter below and gradually rise upwards. On the other side there is a thermometer, enclosed for protection in a brass tube, which is open below. The mercurial bulb lies in the water, about half-way between the floor and the lid, while the scale, which reads in half degrees Centigrade, is outside the apparatus. In the centre of the lid there is a circular opening into which the part designed for the reception of the McGowan's tubes is fitted.

The inner cylinder is of glass, 5 in. long and 1½ in. in diameter, and is so placed that it is nearly equally distant from the lid, floor, and sides of the outer cylinder. It is open at the end next the hole in the lid of the outer cylinder. Through these openings both cylinders can be filled with water at 20° C., the inner to the brim, the outer not quite to so high a level, so that when water has to be added it may not overflow into the place where McGowan's tubes are placed. These cannot be put directly into the water of the inner cylinder, because when a part of a tube is broken off to test for the presence or absence of fibrin the water would come into direct contact with the blood when it was replaced. This is avoided by having five brass tubes in the inner cylinder into which they can be put.

These open round the circumference of a brass plate which closes the inner cylinder. Another plate closes the opening in the lid of the larger cylinder, and through the centre of both plates runs a thermometer protected by a closed brass tube, the bulb lying in the centre of the inner cylinder, so that the reading indicates the temperature of the air in the tubes in which the McGowan's tubes lie.

Six small holes, 2 mm. in diameter, in the outer plate correspond in position to the openings of the six tubes in the plate which closes the inner cylinder. Small funnels are placed over these openings to facilitate the introduction of the glass tubes.

In obtaining the blood, a fairly large drop should follow the puncture immediately. This does not occur if the patient's hands are cold, and so it is often necessary to warm them first with a hot-water bottle. Then, if a slip-knot is tightened round the base of the thumb, an entirely painless puncture on the extensor surface near the nail will immediately produce a sufficient quantity of blood.

The best thing to use for pricking the finger is, I think, Jenner's vaccinostyles. One of McGowan's tubes, 8 in. instead of 6 in. long, is then taken and introduced into the drop of blood until about 4 in. have been filled. The other end is then closed with sealing-wax and it is put into the apparatus. The time at which the blood appears is noted. This is repeated with two more tubes, using each time a new prick and making a fresh puncture.

It is essential that there should be no contact with the blood from previous punctures. The apparatus contains receptacles for six tubes, so it is possible to fill and introduce three others from another patient before it is time to examine the first tubes for fibrin.

After eight minutes the first tube is taken out. It is held by the left hand in forceps covered with rubber in order to avoid contact with the fingers which would considerably raise the temperature of the blood. A slight scratch is made with a glass file about ¼ in. from the end. This part is then carefully broken off by the finger and thumb of the right hand, and the two fractured ends drawn slowly apart, holding them up against the light. If a fine filament of fibrin is seen, it is not to be taken as indicating coagulation, but only as showing that the end-point is near.

The reason for this is that the blood at the end of the tube is the part of the blood which has left the wound. This coagulates sooner than the blood which first appears, and as the amount of this acceleration is constant, it is better to disregard it, and to take as the end-point the appearance of a thread of fibrin only in the last inch of the blood. The tube is, therefore, broken a little higher up, and if, as often happens, no fibrin is seen, it is returned to the apparatus and the second tube is taken. The difference between the times when the three drops of blood appeared and the time when a fibrin thread was seen in the last part of the tubes, gives three coagulation times, and the average of these is taken as representing the approximate coagulation time of the blood in the case in question. This tends to reduce the error arising from the deficiency in delicacy of the end-point.

Of course a certain amount of error arises from the fact that the tube must be removed from the apparatus into a medium of inconstant temperature in order to test for the presence of coagulation, but as this time is short, and as there is not a great difference between the ward temperature and 20° C., it is not of great importance.

Altogether, I am convinced that, so far, this is the only method, clinically applicable, which yields results upon which reliance may safely be placed.

The limits of experimental error for this modification of McGowan's method were determined in the following way. I had already found, in observations with my method extending over several months, that my own coagulation time was constant from day to day. It was, therefore, fair to assume that any irregular

variations found in making daily determinations with this method were due to experimental error.

The average of three readings at 20° C. was taken as representing the coagulation time of my blood, and this was repeated daily for fifty days. The average of these fifty observations was 9 min. 50 sec., and the average

A. The complete apparatus with the McGowan's tubes in position.

B. The separator parts. 1. The lid of the outer cylinder. 2. The thermometer enclosed in a tube open at its lower end. 3. The opening through which the part designed for the reception of the McGowan's tubes fits. 4. The plate which closes the opening in the lid of the outer cylinder. 5. The plate which closes the inner cylinder.

variation from this mean was 34 sec.; while the possible variation is given by the longest and shortest times—that is, 11 min. 41 sec. and 8 min. 45 sec.; that is, 1 min. 51 sec. above and 1 min. 5 sec. below the average.

In a large number and variety of pathological conditions only a very small percentage of cases were met with in which the coagulation time overstepped these limits, and these were patients who were very seriously ill. In one or two of these daily observations disclosed variations so progressive and considerable that there appeared to be good reason to suspect a real change in the coagulation time of the blood, but further observations will be necessary to confirm this. In all the other cases daily readings gave slight irregular variations within the limits of experimental error, indicating that in all probability the coagulation time would have been found to be constant if a perfectly accurate method had been used.

The approximate accuracy of the method having been thus determined, the following plan was adopted in order to test the value of calcium lactate and citric acid. A period of about eighteen days was divided into three periods of six days, and during the whole time the coagulation time was taken every other day. During the first period neither calcium nor citric acid was taken, while in the second period calcium was given, and in the third citric acid, or vice versa. This was carried out in 8 cases, namely:

Two of thrombosis.

Advanced arterio-sclerosis with a failing heart and general oedema.

Marked jaundice probably due to cancer of the liver. Tuberculous peritonitis.

Lobar pneumonia.

Lead poisoning with chronic interstitial nephritis.

Dysentery.

Each coagulation time given represents the average of three observations. The calcium was given as calcium lactate dissolved in water. The total average of the coagulation times taken under these three conditions shows that neither the calcium nor the citric acid had any effect:

	Total Average Coagulation Time.
Period without calcium or citric acid	9 min. 39 sec.
Period in which calcium was taken	9 min. 31 sec.
Period in which citric acid was taken	9 min. 34 sec.

The following are the details by which it can be seen that in none of these cases was there at any time any indication of a change in the coagulation time during the administration of calcium or citric acid:

G. G., aged 59. Thrombosis of left internal sphenous vein.

1. Period without calcium lactate or citric acid:
First day, 9 min. 53 sec. Third day, 11 min. 20 sec. Fifth day, 10 min. 50 sec.
2. Period during which citric acid 30 grains was given 4-hourly:
Sixth day, 10 min. 0 sec. Eighth day, 10 min. 20 sec. Tenth day, 9 min. 35 sec.
3. Period during which calcium lactate 60 grains was given 4-hourly:
Twelfth day, 9 min. 40 sec. Fourteenth day, 10 min. 10 sec. Sixteenth day, 9 min. 10 sec.

J. C., aged 61. Thrombosis in veins of right lower extremity. Cause unknown.

1. Period without calcium lactate or citric acid:
First day, 10 min. 39 sec. Second day, 9 min. 40 sec.
2. Period during which citric acid 30 grains was given 4-hourly:
Third day, 9 min. 20 sec. Fifth day, 9 min. 40 sec. Seventh day, 9 min. 0 sec.
3. Period during which calcium lactate 30 grains was given 4-hourly:
Ninth day, 9 min. 20 sec. Eleventh day, 9 min. 55 sec. Thirteenth day, 10 min. 0 sec.

J. L., aged 48. General arterio-sclerosis, aortic and mitral incompetence, general anæmia.

1. Period without calcium lactate or citric acid:
First day, 8 min. 30 sec. Second day, 8 min. 15 sec.
2. Period during which citric acid 30 grains was given 4-hourly:
Third day, 9 min. 30 sec. Fifth day, 9 min. 40 sec. Seventh day, 9 min. 15 sec.
3. Period during which calcium lactate 30 grains was given 4-hourly:
Ninth day, 10 min. 15 sec. Eleventh day, 8 min. 50 sec. Thirteenth day, 8 min. 20 sec.

O. H., aged 65. Deeply jaundiced. Symptoms suggested cancer of the liver.

1. Period without calcium lactate or citric acid:
First day, 8 min. 50 sec. Third day, 9 min. 40 sec. Fifth day, 10 min. 10 sec. Seventh day, 9 min. 35 sec.
2. Period during which calcium lactate 15 grains was given 4-hourly:
Ninth day, 9 min. 40 sec. Tenth day, 9 min. 30 sec. Twelfth day, 8 min. 50 sec.
3. Period during which citric acid 30 grains was given 4-hourly:
Fourteenth day, 9 min. 10 sec. Sixteenth day, 10 min. 50 sec. Eighteenth day, 9 min. 30 sec.

N. I. T., aged 25. Tuberculous peritonitis.

1. Period without calcium lactate or citric acid:
First day, 10 min. 10 sec. Third day, 10 min. 35 sec. Fifth day, 10 min. 0 sec.
2. Period during which calcium lactate 30 grains was given 4-hourly:
Seventh day, 9 min. 15 sec. Ninth day, 9 min. 55 sec. Eleventh day, 10 min. 10 sec.
3. Period during which citric acid 30 grains was given 4-hourly:
Thirteenth day, 10 min. 45 sec. Fifteenth day, 10 min. 10 sec. Seventeenth day, 10 min. 30 sec.

F. W., aged 17. Lobar pneumonia. Crisis on second day.

1. Period without calcium lactate or citric acid:
First day, 9 min. 30 sec. Second day, 9 min. 50 sec. Third day, 9 min. 10 sec.
2. Period during which citric acid 30 grains was given 4-hourly:
Fifth day, 9 min. 10 sec. Seventh day, 9 min. 40 sec. Ninth day, 9 min. 15 sec.
3. Period during which calcium lactate 30 grains was given 4-hourly:
Eleventh day, 9 min. 30 sec. Thirteenth day, 9 min. 25 sec. Fifteenth day, 10 min. 30 sec.

G. O., aged 37. General arterio-sclerosis and chronic interstitial nephritis, the result of lead poisoning. Severe headaches, vomiting, and colic for the first seven days.

1. Period without calcium or citric acid:
First day, 10 min. 10 sec. Third day, 9 min. 25 sec. Fifth day, 11 min. 10 sec.
2. Period during which calcium lactate 30 grains was given 4-hourly:
Seventh day, 10 min. 20 sec. Ninth day, 11 min. 35 sec. Eleventh day, 10 min. 10 sec.
3. Period during which citric acid 60 grains was given 4-hourly:
Thirteenth day, 9 min. 55 sec. Fifteenth day, 10 min. 25 sec. Seventeenth day, 10 min. 0 sec.

W. W., aged 35. Dysentery.

1. Period without calcium or citric acid:
First day, 7 min. 45 sec. Third day, 8 min. 15 sec. Fifth day, 8 min. 20 sec.
2. Period during which calcium lactate 15 grains was given 4-hourly:
Seventh day, 8 min. 35 sec. Ninth day, 7 min. 35 sec. Eleventh day, 7 min. 20 sec. Thirteenth day, 8 min. 15 sec.
3. Period during which citric acid 30 grains was given 4-hourly:
Fifteenth day, 8 min. 15 sec. Seventeenth day, 8 min. 45 sec. Nineteenth day, 8 min. 45 sec.

Some observations were made on patients with typhoid fever, but the results are not comparable with those given above, because a less accurate and constant technique and one which tended to give shorter times was then used. So far as they go, however, they fail to show that any change was produced on the coagulation time, for in seven patients who were taking citric acid, the average of 27 estimations was 7 min. 57 sec., while the average of 39 estimations in two patients who were taking calcium was 8 min. 43 sec.

A well-marked case of hæmophilia with a characteristic family and personal history was admitted for hæmorrhage of four days' duration following on the extraction of a tooth. On the second day after admission, the bleeding still continuing, the coagulation time was 12 min. 35 sec. at 7.30 p.m. At 7.45 p.m. 60 grains of calcium lactate in solution were taken, but two and three hours later the coagulation time was 14 min. 30 sec., and no effect had been produced on the bleeding, which continued for four days more, and ultimately appeared to be stopped by the application of a pledget of cotton-wool soaked in the blood of another person.

A case of urticaria was found to have a coagulation time of 10 min. 15 sec. Calcium lactate was given 4-hourly, and on the two following days the times were 10 min. and 10 min. 15 sec. During these two days the urticaria gradually disappeared, but this was not because the coagulation time had been shortened by the calcium; the urticaria was due to another cause.

These results are, no doubt, few in number, and since no cases of chilblains or of physiological albuminuria are included, do not cover all the territory which Sir A. E. Wright claims for calcium and citric acid, but as in no single instance was any effect whatsoever found to follow their use I think that the general conclusion that they are unable to effect any change in the coagulation time of the blood is fully justified.

As I have shown elsewhere, the reason for this is that the increase or decrease in the content of the blood in ionisable calcium which follows their administration is far smaller than that amount of change which is necessary to produce an appreciable effect on the coagulation time.

I have to thank Dr. A. K. Gordon, of Monsall Fever Hospital, and Dr. Oscar Clark and Dr. Grosvenor, of Gloucester General Infirmary, for having kindly allowed me to make these observations on patients under their charge.

A CASE OF TYPHOID COMPLICATED WITH STAPHYLOCOCCAL SEPTICAEMIA.

N. E. ROBERTS, M.B., C.M., D.P.H.,
VISITING PHYSICIAN, GRAFTON STREET HOSPITAL; LECTURER IN INFECTIONS DISEASES, UNIVERSITY OF LIVERPOOL.

and E. E. GLYNN, M.A., M.B.CANTAB., M.R.C.P.,
LECTURER IN CLINICAL PATHOLOGY, UNIVERSITY OF LIVERPOOL; BACTERIOLOGIST TO THE LIVERPOOL ROYAL INFIRMARY.

The clinical and bacteriological history of this case prove that it was one of typhoid fever, complicated at the end of the second week by a secondary generalized infection with *Staphylococcus albus* and *aureus*.

A nurse at the Liverpool City Hospital, Grafton Street, aged 29, after three months' typhoid work, was transferred to night duty in the scarlet fever wards. On October 31st, 1908—eleven days later—she complained of not feeling well, and was therefore taken off duty. Indefinite symptoms characterized the onset of the illness up to November 5th, when the probability of enteric fever arose, and this was the provisional diagnosis till November 13th. It is sufficient to state that, though the classic signs were not prominent, the weight of evidence was in favour of enteric. Pyrexia was fairly typical, there were two doubtful spots, the spleen was palpable, and Ehrlich's diazo-reaction was positive.

At 8 p.m. on November 13th—probably the fourteenth day of the disease—the patient had the first of a series of severe rigors, which recurred at intervals during the next nine days, giving an unusual clinical picture in typhoid. The rigors lasted from twenty minutes to half an hour, and were followed, as a rule, by a profuse perspiration (see Chart).

As the symptoms were associated with the development of a marked apical systolic bruit, and accentuation of the pulmonary second sound, and as on November 9th the Grunbaum-Widal reaction was negative, it was thought that the case might be one of infective endocarditis simulating typhoid at its onset.

On November 18th, therefore, a bacteriological examination of the blood was undertaken. The skin of the arm was sterilized; 10 c.cm. of blood were withdrawn from the median cephalic vein, and distributed among three flasks containing 100 c.cm. of broth and half a dozen slant agar tubes. After forty-eight hours the flasks contained staphylococci, and a Gram-negative motile bacillus with many flagella. This bacillus, after it had been subcultured for several weeks, was agglutinated markedly in half an hour with the serum of a convalescent typhoid patient in dilutions of 1 in 15, 1 in 30, and 1 in 60, but not with normal serum. The bacillus also behaved in a manner characteristic of typhoid in glucose, lactose, cane sugar and mannite broths, litmus milk, gelatine, and broth.

All the slant agar tubes, each of which contained only a few drops of blood, were covered with colonies of *Staphylococcus aureus* and *albus*, in about equal proportion, but the colonies were too numerous to count satisfactorily. No typhoid-like colonies were visible. Streptococci were absent in all the cultures.

The bacteriological diagnosis of typhoid was further confirmed by the fact that, although on November 9th the Grunbaum-

January 8th. The cardiac bruit had in the meanwhile completely disappeared.

The occurrence of intermittent pyrexia is common enough in the third and fourth week of typhoid, but one of us, who has seen over 3,000 hospital cases of this disease, cannot recall having met with such extreme and unaccountable variations in temperature, combined with repeated rigors, moreover, in the second week of the disease.

The source of the secondary infection with staphylococci could not be discovered though assiduously looked for, but it is worthy of note that the patient immediately before her illness had been nursing scarlet fever, a disease intimately associated with infective processes.

Another point of interest is the fact that the patient prior to the bacteriological diagnosis was treated with antistreptococcus serum, with apparently beneficial results, so it was deemed prudent to continue its administration, notwithstanding the absence of streptococci in the blood.

HOW MUCH FLUID DOES THE BODY REQUIRE?

By ALEXANDER HAIG, M.A. and M.D. OXON., F.R.C.P.,

SENIOR PHYSICIAN TO THE METROPOLITAN HOSPITAL, AND TO THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.

If a man living an ordinary sedentary life, not entailing visible perspiration, takes from 50 to 60 oz. of fluid per diem, then a weight of 150 lb. apparently requires about 50 oz. of fluid, this amount being passed each day through the kidneys. The question is, By how much may this quantity be reduced before physiological difficulties are encountered?

The teaching of the late Sir Andrew Clark on the importance of reducing fluid in cases of morbus cordis first arrested my attention, and I have followed his teaching in such cases with much benefit. In none have I seen urinary gravel induced by reduction of fluid in those who had not previously had gravel. Working at the circulation in high blood-pressure cases (for example, headache, epilepsy, and depression), I found that by lessening fluids I could lower blood pressure 20 or 30 mm. of mercury, this often sufficing to turn the balance.

The above quantities of fluid are more a habit than a necessity, and most people can accustom themselves to do with less than 50 oz. a day. I generally aim at 30 oz. The gain to a diseased or dilated heart is obvious; the total fluids in the body are gradually reduced by several pints, and weight falls a corresponding number of pounds.

A dilated heart resembles a distended bladder, and the latter, we know, may lose all power of expulsion. A heart thus enabled to get a more complete grasp of its contents not only saves a great expenditure of force in twenty-four hours, but valves incompetent in the dilated condition may, even though diseased, become almost completely competent. It is no uncommon thing for the transverse area of the heart to diminish 2 in. in three weeks, even if no drugs are given and no other change made.

I wrote in 1903¹ on the washing out plan, mentioning that I had seen a number of cases in which an attempt to wash out an excess of uric acid had been quite unsuccessful, because uric acid controls the passage of water out of the body, while the water does not to any important extent control the excretion of uric acid. I there mentioned some cases in which excess of fluid had dilated the heart, leading to atrophy of its muscular tissues, and leaving little but a prospect of chronic invalidism.

On a dry diet I have seen astonishing recoveries from morbus cordis. In one case almost no fluid was taken except that in fruit, and the patient passed from hopeless invalidism to the power of bicycling fifty to sixty miles in a day with ease.

The relief from reduced blood-pressure alone is no small

A, Serum reaction—(1-15); B, rigor; C, blood cultured; D, serum reaction + (1-60); E, slight rigor.

Widal reaction, tested at the Municipal Bacteriological Department, was negative, on November 18th, unknown to us, it was reported positive in dilutions up to 1 in 60.

The patient, who was treated for the septicaemia with injections of antistreptococcus serum twice daily, had the last rigor on November 21st, and was discharged cured on

matter for an organ which has to work the whole twenty-four hours, and I have always agreed with the late Sir W. H. Broadbent that we do more good by diminishing the heart's work than by driving it on with tonics.

Consider the condition of the heart, placed in a practically unyielding investment (the pericardium); every dilatation means pressure, and pressure means at least defective circulation in the cardiac veins and capillaries, to say nothing of the influence of the defective action of the left ventricle on the cardiac arterial supply. Thus every dilatation of the right side, if it increases intrapericardial pressure, must mean defective circulation in every muscle fibre of the heart. This risk is removed by lessening fluids, and in morbus cordis this also diminishes the strain on the valves, and so the tendency to recurrent endocarditis.

On the heart the effect is not only to diminish work and aid its mechanical efficiency but also to improve its nutrition enormously. The pressure in the whole arterial system is diminished, and the importance of this in advanced cases of arterial disease or impending cerebral haemorrhage needs no demonstration. The capillaries and venules are no longer over-distended and liable to rupture. The veins previously visible and prominent, especially in the lower limbs, shrink and disappear, and the very texture of the tissues becomes firmer and harder. This was well seen in the case of morbus cordis above mentioned, where fluid was taken chiefly in fruit. In place of the flabby limbs of a beer-drinking butcher this patient developed the iron-wire muscles of our nearest frugivorous relatives. The frugivora, I believe, take little fluid, and that mostly in the form of fruit.

Such changes as I describe profoundly affect the whole vascular system. Several times lately I have been called to see cases of aneurysm in which, I know not why, no attention had been paid to the quantity of fluid. One of these patients was so bad with dyspnoea that I scarcely dared to move him for examination. I found that he was taking 2½ pints of fluid a day. Four weeks later, as the result of reduced fluids, he was walking about, and only sat down for examination. The aneurysm was not cured, but life, which was threatened by the distension of high blood pressure, was at least prolonged.

In the dilated and splashing stomach commonly found with chronic collaemia there is often in addition an increase of heart area, and a capillary reflux of 7 to 8 with a blood pressure of 130 or less, and a quick, often irregular pulse, with palpitation on exertion. A capillary reflux of 7 with a strong heart should show a blood pressure of 140, and one of 8 a blood pressure of 160; thus we can measure the extent of the heart failure. These conditions are commonly seen together, and collaemia is the central factor. When the heart is already overweighted by high blood pressure it is most injurious to give excess of fluids in the false hope of washing out excess of uric acid. Excess of fluid is slowly absorbed from the stomach; while there it dilutes the digestive juices and favours fermentation; when absorbed it dilutes the digestive secretions, diminishing their power, and favouring the increase of microbic putrefaction, malnutrition, and debility. Its tendency is to dilate the stomach muscles of which are, like those of the heart, in poor condition from defective circulation. As a result of such malnutrition and debility excess of fluid will eventually produce some oedema of the ankles, which is not infrequently accompanied by oedema of the cortical membranes, which lies at the root of brain-fag and debility, commonly called "nerves"; of bad temper, nervous excitement, hysteria, or of neurasthenia, depression, and lethargy up to the more fully-developed signs of uraemia—for example, twitching of muscles, headache and coma. Many of these conditions are often promptly relieved and may be cured by lessening fluids, strengthening the heart, and later on removing collaemia by a purin-free diet. I believe that no small part of the increase of such "nerve" troubles is due to increased consumption of fluids, especially where the increase of fluid is not accompanied by any measure to diminish the introduction of uric acid. As a rule collaemic sufferers dislike fluids. Their blood contains excess of fluid, and shows only small percentages of haemoglobin and cells, since the capillaries of all the organs of excretion (kidneys, skin, lungs) are blocked by collaemia. These patients are

easily persuaded to take less fluid, and generally have to be urged to take excess.

Albuminuria and Bright's disease are an additional indication for this treatment, for at least a part of the defective combustion, called Bright's disease, is due to cardiac weakness, and anything improving the condition of the central organ of the circulation improves the general combustion.

The treatment of collaemia with heart failure and its results is to cut down fluids but not to reduce the income of proteids—for no heart tonics will act if food is deficient; to rest the whole body as much as possible so as to lessen the work of the heart; to give heart tonics such as digitalis or nuxvomica in small doses long continued, till the pulse rate is normal and the natural ratio between capillary reflux and blood pressure re-established. I used to be puzzled by cases of neurasthenia and depression in which there were obvious indications for heart tonics, and yet the administration of such tonics made the mental condition worse. In these cases there is always high blood pressure, and to raise the pressure in the skull still more by tonics will do harm so long as there is cerebral oedema; but remove the oedema by diminishing fluids, and the tonics can then be given with benefit. The same applies to the heart—take off the work and improve its mechanical power by diminishing fluids, and the tonics will do treble the good in half the time.

What harm may be done by diminishing fluids? Uric acid gravel, or the presence of large quantities of urate in the ears, joints, and fibrous tissues, forbid diminution of fluid over a long period, for the excretion of such urate store is almost certain to give trouble in the tubules and pelvis of the kidneys if sufficient fluid is not taken. Yet when a patient is obviously dying of heart failure on the one hand, or cerebral oedema on the other, we must immediately cut down fluids and consider the excess of urates afterwards. There might be increased tendency to thrombosis, but, as the ultimate effect is a general improvement of the circulation, this does not seem important, especially if a purin-free diet is adopted.

Constipation is another possible trouble, and sufferers on an ordinary diet will not be better on diminished fluids. But what is the inconvenience of a little constipation if weighed in the balance against heart disease, or uraemia, or cerebral oedema? The use of common laxatives will counteract it while matters are critical, and later there will not be much trouble from constipation if fruit is used daily.

In serious conditions I take thirst as a guide, and I find that most patients can reduce their fluids to 30 oz. a day, and, with the help of fruit, to 25 oz., 20 oz., or less, at least for a time. If salts, salines, and diuretics are given more fluid will be called for, and then we have to decide whether most good is done by withholding drugs and water, or by giving both. As a rule, I am in favour of the former course, though drugs can be used at first, as it takes several days to reduce the fluids of the body. I order that 30 oz. be aimed at, but that fruit or extra water shall be given whenever thirst imperatively demands it.

THE OCCURRENCE OF TUBERCLE BACILLI IN THE BLOOD IN TUBERCULOSIS.

BY

CHARLES E. P. FORSYTH, M.B. ABERD., M.R.C.P. LOND.,
PATHOLOGIST TO THE LIVERPOOL HOSPITAL FOR CONSUMPTION AND
DISEASES OF THE CHEST; LATE ASSISTANT PATHOLOGIST IN
THE LONDON SCHOOL OF CLINICAL MEDICINE, SEAMEN'S
HOSPITAL, GREENWICH, S.E.

It appears to have been little, if at all, recognized that tubercle bacilli may commonly be found in the blood of tuberculous patients.

Very recently Rosenberger¹ published a remarkable series of cases which must bring the question of blood infection in this disease into prominent notice. The cases he examined included many different forms of tuberculosis, and he was able to demonstrate the bacillus in the blood of every patient, whatever the type of the disease, and however early the disease appeared to be clinically. It is

clearly of great importance that his conclusion as to the occurrence of blood infection in every case of tuberculosis should be tested. To mention one matter—if it be completely proved that living tubercle bacilli occur in the blood of practically every tuberculous patient, no matter how early or circumscribed the lesion appears to be, it is without doubt that our ideas as to the use of vaccine-therapy—tuberculin—must be considerably modified.

Using to some extent his methods, I have examined the blood in 12 cases of pulmonary tuberculosis. The method of examination is simple, and is, shortly, as follows:

Method.

The skin of the front of the forearm is thoroughly cleansed with liquid soap, alcohol, and ether. A tourniquet is applied, and, with a sterile syringe fitted with a platinum-iridium needle previously flamed, about 5 c.cm. of blood are drawn from any convenient vein. The blood is at once mixed with about an equal volume of sterile citrated salt solution. The mixture is placed in a swift-running centrifuge for twenty minutes, and some of the deposit taken up on a slide to form a thick film. This is dried in an oven at 60° C., and is then placed in sterile distilled water to lake the blood. Thereafter the film is fixed and stained in the usual way.

It is important to state that every precaution is taken against risk of contamination. A new pipette and new slides, kept in strong sulphuric acid, are used in each case. The centrifuge tubes and flasks are cleansed with caustic soda, pure sulphuric acid, and sterile distilled water, and similar care is taken with the syringe.

Out of the 12 cases, 10 had distinct physical signs and had tubercle bacilli in the sputum. Adopting Turban's classification, there were of Stage I 3 cases, of Stage II 6 cases, and of Stage III 1 case. This gives a total of 10, and all these 10 showed tubercle bacilli free in the blood.

The organisms were of the long or short forms, beaded or uniformly stained, and were acid-fast rods morphologically indistinguishable from the tubercle bacillus. There seems little possibility of doubting their identity with it; seen in the sputum they would be judged absolutely diagnostic.

In each case they were few in number; no groups were seen; usually the bacillus was alone in the field, or at most two appeared together. They were found with more or less difficulty. Often only one was seen after long and laborious search over a whole slide, and in a few cases two and three and four slides had to be examined before success. In one case phagocytosis was noticed, and only in one was there evidence of mixed infection in the blood. In this a diplococcus was seen in fair numbers, and it is being further investigated.

The result of cultures from the blood of these cases and the result of the inoculation of the infected blood into animals remain to be worked out.

One of the two cases in which no amount of search could show the bacillus was a patient with very indefinite symptoms and physical signs, and altogether of doubtful diagnosis. In the other case the physical signs were marked, but repeated examination had never revealed tubercle bacilli in the sputum.

Only 4 of the 10 cases giving a positive result had any fever at the time of examination of the blood. In the other 6 the temperature was normal, and had been so for many days or weeks, all of them getting about well, and showing, in short, the usual chronic course of the disease. I state this to draw attention to the fact that they were by no means rapidly progressing acute cases, or cases of general tuberculosis.

I have to express my thanks to Dr. Henry Clarke, Honorary Superintendent of the Research Laboratory, for kind advice and help, and to the other physicians of the Liverpool Hospital for Consumption and Diseases of the Chest, for the facilities they have given me in this matter.

The fifth International Congress of Dental Surgery will be held at Berlin from August 23rd to 28th. The work of the Congress will be distributed among twelve sections. The General Secretary is Dr. Schaeffer-Stuckert, of Frankfurt-on-Main (Kettenhofweg, 29), to whom all communications relative to the congress should be addressed. In connexion with the congress there will be an exhibition.

CHRONIC NEPHRITIS TERMINATING WITH HAEMORRHAGE FROM THE BOWEL AND PERFORATION OF THE BOWEL.

By LEONARD G. J. MACKEY, M.D., CH.B. BIRM.,

PATHOLOGIST AND PHYSICIAN TO OUT-PATIENTS AT QUEEN'S HOSPITAL, BIRMINGHAM.

THE complications of chronic nephritis are numerous and for the most part well recognized, but the following case presents some unusual features, and calls attention to a dangerous complication about which very little appears to have been written:

A married woman, aged 27, was admitted into Queen's Hospital on account of profuse hæmorrhage from the bowel.

She looked very pale, ill, and thin, and said she had not been really well for three years; and that since the birth of a stillborn child about a year before, she had suffered from vague pains in the epigastrium and in the lower part of the abdomen. On examination of the abdomen there was neither pain, tenderness, nor rigidity. The temperature was normal and remained within normal limits till the day of her death; the heart was hypertrophied and the second aortic sound accentuated; the pulse 112 and of high tension. The urine showed a cloud of albumen and one or two granular casts.

For the two days following admission the motions were fluid and dark with blood; after that they became light in colour, but on several occasions small dark red clots were found. The patient remained quite free from pain, the abdomen was soft and flat and nowhere tender. Feeding was limited to nutrient enemata. Bacteriological examination of the faeces revealed nothing unusual.

Before admission she had been treated for gastric ulcer, and after admission the diagnosis of gastric or duodenal ulcer was considered, and with it the advisability of operation; but the site of the hæmorrhage was uncertain and the patient seemed to be improving, so it was decided to do nothing till she had been a little longer under observation.

On the seventh day after admission she became suddenly collapsed and complained of severe abdominal pain; she rapidly developed the signs of a perforative peritonitis and died on the following day.

Necropsy.

The peritoneal cavity contained a quantity of thin, blackish, offensive fluid, which had obviously escaped from the small intestine through three perforations, which could be seen in the lower end of the ileum. The lower 6 or 7 ft. of the small intestine and the caecum were blackened with numerous hæmorrhages into the wall of the gut, and on opening the bowel I found more than 100 small ulcers in the lower portion of the small intestine. The ulcers were all small, the largest being about 1 in. in diameter, and round or oval; each ulcer seemed to have originated in a patch of hæmorrhage, though there were many hæmorrhages which had not ulcerated; they varied in depth, many had reached the peritoneum, and three had perforated, while others were quite shallow and involved no more than the mucous membrane. The edges of the ulcers were not raised; Peyer's patches were not prominent. The remainder of the alimentary canal appeared to be healthy.

A careful examination of the mesenteric vessels was made and a microscopic examination of the wall of the intestine, but it threw no light on the immediate cause of the hæmorrhages, though it seemed clear that the ulcers were due to invasion of the hæmorrhages by micro-organisms from the bowel.

The kidneys were pale, granular, and contracted, and microscopically showed all the changes of a chronic interstitial nephritis and a great degree of endarteritis of the smaller vessels.

The heart was large and showed marked hypertrophy of the left ventricle.

Quite recently a similar case came under my notice:

A man aged 28, a lead worker, was admitted into the Queen's Hospital suffering from chronic nephritis and arterio-sclerosis, and died suddenly from a cerebral hæmorrhage. The autopsy revealed a marked hypertrophy of the heart and degenerated arteries, a large cerebral hæmorrhage, and an advanced interstitial nephritis, but in addition the lower 6 ft. of small intestine was blackened with numerous small hæmorrhages into its wall, exactly as in the previous case; and on opening the bowel I found superficial ulcers forming in many of the hæmorrhagic spots; but in this case there had been no hæmorrhage into the lumen of the bowel, I take it because the ulceration was not sufficiently advanced.

Thus two very similar cases, differing only in degree, have been seen within a few months of each other in the post-mortem room of a comparatively small hospital, so it is not likely that the condition is one of very great rarity, though it must be one which it is important to recognize.

Whether these two cases must be regarded as cases of hæmorrhage due to increased blood pressure, or whether we must look for some change in the mesenteric vessels, or for some toxin in the part of the bowel affected, I am

not in a position to say, but one cannot help feeling that there is some connexion between the lesion in the bowel and the condition of the kidneys. With a powerful heart and diseased arteries we expect cerebral and retinal haemorrhages and epistaxis as a matter of course. Why, then, should the vessels of the stomach and intestine remain intact?

I beg to thank Dr. Douglas Stanley and Dr. Foxwell, of Queen's Hospital, for permission to publish this note concerning their cases.

ROENTGEN CINEMATOGRAPHY AND ITS IMPORTANCE IN MEDICINE.

By Dr. FRANZ M. GROEDEL,

BAD-NAHEIM.

SCIENTIFIC cinematography has two chief aims—first, to represent a series of movements on the screen; and, secondly, to analyse movements.

Roentgen cinematography has the same two aims in view. As yet, however, no positive result has been achieved. A few investigators (I may mention Macintyre, Levy-Dorn, Eykman, and Alban Köhler) have indeed succeeded, by a skilful combination of views taken at different times, in projecting certain movements of the body on the screen. Apart from the great didactic value of this combination of views no real scientific importance can be claimed for them.

The analysis of a movement is of far more importance than its pictorial reproduction. We can watch the process of the movement on the screen with tolerable distinctness, though not demonstrate it so well as by a cinematographic projection, by which everything is reproduced on an enlarged scale. In many cases, however, it is almost impossible to distinguish the various phases of the movement, owing to the well-known slowness of the human eye, or, rather, of the retina. It will not be until we come to study heart, stomach, and breathing movements by means of cinematographic views that this question will be finally cleared up.

For the production of real Roentgen cinematograms the shortest possible exposure is requisite. The way pointed out by me¹ to attain this has since been followed by several investigators, and experience has confirmed my statements. With every good inductor it is possible, by employing a primary current of sufficient strength, to produce views of the thorax with film intensifiers in $\frac{1}{10}$ to $\frac{1}{20}$ second.

Having thus, a year ago, succeeded in fulfilling this first necessary condition, I immediately proceeded to construct an apparatus for taking a series of Roentgenograms. It soon appeared that there were very considerable difficulties to be overcome, a detailed account of which in this place would lead me too far.² It will suffice here to describe in brief the main principles of my Roentgen cinematograph. A number—for example, 24—of strong drying boxes, each containing a film between two intensifiers, are gradually moved forwards by means of a slide. Immediately in front of a leaden screen supplied with a corresponding opening, against which the patient leans, the drying boxes fall through a slit into a case, which is proof against Roentgen rays. The tube is attached behind the patient. In front of the tube moves a large leaden disc, 1 cm. thick, which contains two openings diametrically opposite each other. When one of the openings is in front of the tube, the foremost plate is exposed, and when the opening is just covered the drying boxes are pushed forward and the foremost plate is then thrown off. The whole apparatus, which weighs more than $1\frac{1}{2}$ cwt., is moved by means of an electric motor. It can take at least four views in a second.

If the apparatus is fixed for an exposure of $\frac{1}{10}$ to $\frac{1}{20}$ second, views of the heart in pulsation, or the diaphragm in motion, can be obtained with extremely sharp outlines. If it is fixed to $\frac{1}{10}$ second, the movements of the stomach can be distinctly reproduced. For joint movements the time of exposure varies according to whether the Roentgenogram is taken with plates or film-

intensifiers. The primary conditions will be found in the work above mentioned.

Thus we are now in a position to reproduce all the movements in the human body by means of Roentgen cinematography, to study the different phases and to analyse the movements, which the human eye itself is mostly unable to do. Much preparatory technical work has still to be done, it is true, but the way has now been cleared.

The question as to what practical use Roentgen cinematography will be to scientific research must at present remain unanswered. Certain motions, such as pulsation of the heart and the involuntary movements of the stomach, can now be examined with scientific exactitude for the first time. As regards other movements, such as breathing, we have yet to ascertain whether the views we have hitherto held were right or not. As has been repeatedly stated, the eye is not properly adapted for analysing a movement. Therefore we are perfectly justified in expecting revelations in quarters which have hitherto seemed perfectly cleared up. It is only necessary to call to mind what a revolution instantaneous photography and cinematography have produced in regard to the pictorial and plastic representation of moving objects.

We shall only be able duly to appreciate Roentgen cinematography from a practical point of view when we have studied cinematographically the changes of the movements in the interior of the body in a pathological condition. In this respect, to quote but a few examples, the study of the pathological state of breathing, the various abnormal forms of heart pulsation, the pathological changes in the movements of the stomach, etc., all afford an ample field for scientific research.

From the tests I have as yet made with this apparatus, I will here only mention that I have already succeeded in reproducing not only the movements of the joints, the stomach, and the breathing, which are comparatively easy, but also the pulsation of the heart, as I fully demonstrated before the Verein für innere Medizin in Berlin on March 1st, 1909.

NOTES ON A CASE OF TETANIC SPASM

WITH REFERENCE TO THE DIFFERENTIAL DIAGNOSIS BETWEEN TETANUS AND STRYCHNINE POISONING.

By W. SINCLAIR STEVENSON, M.B., CH.B. EDIN.

HOUSE PHYSICIAN, ROYAL BERSHIRE HOSPITAL.

THE following case illustrates very well the difficulty which is occasionally met with in the differential diagnosis of tetanus and poisoning by strychnine:

L. H., a young woman of 24, unmarried, was admitted to the Royal Berkshire Hospital on a Wednesday suffering from intermittent spasm of the face and trunk. It appeared that she was a domestic servant, though she had left her last place a fortnight before, and had since been living at home. She said that she had twice recently fallen downstairs. There was no history of any other accident. Three days previously she noticed that the muscles of her face and lower jaw began to contract spasmodically. By the following day the muscles of the face were less affected, but the jaws were firmly closed, and could not be separated. On Tuesday her back became affected, and she assumed a position of mild opisthotonos.

Condition on Admission.

When seen on Wednesday evening she was in a very weak state. The pulse was rapid and compressible. Temperature 102°. Respirations 30. The muscles of the lower jaw, neck, and back were in a state of tonic contraction, the lower jaws about 4 in. apart, and it was impossible to separate them any wider without using undue force. The muscles of the face were unaffected, but the head was retracted in a moderate degree, and the trunk was arched backwards and was quite rigid. The abdomen remained soft and could be palpated without difficulty during the severest spasms. Her arms were affected to some extent, the elbows being firmly pressed in to the sides and the forearms flexed and supinated; the hands were flexed on the forearms. Her lower limbs were stiff and the feet flexed as a rule, but could easily be straightened. The rigidity of the legs was sufficiently marked to prevent the successful testing of the reflexes. Respiration was shallow and rapid, but regular. The spasms, as a whole, showed periods of exacerbation, but even during these the respiration, though more rapid, remained

¹ I leave a full description of the apparatus constructed for me by Messrs. Reinster, Gubbert, and Schell, in Erlangen, in the *Deutsche med. Wochenschrift*, 1909, No. 10.

perfectly regular, and there were no signs of dyspnoea. The urine was of high specific gravity and contained a slight trace of albumen. Unfortunately, no attempt was made to ascertain the presence or absence of strychnine in the urine.

After she had been kept quiet in bed the tonic contractions passed off to some extent. She remained in the position of opisthotonos and her head was retracted throughout, but all the other muscles relaxed considerably.

From this time onward she suffered from periodic tonic contractions of the muscles mentioned before at varying intervals; sometimes the attacks would come on every other minute, and then again she would have no attacks for a couple of hours. As the end approached they became increasingly frequent, and at last almost continuous, but in spite of this her breathing was scarcely affected.

She was able to take her fluid food well and could speak intelligibly, but scarcely moved her jaws in doing so. Discomfort was complained of during the attacks, but apparently she never had any actual pain. There was no vaginal discharge, and till an hour before her death she was in possession of all her faculties.

She was given three injections of tetanus antitoxin—chloral and bromides in large doses had been tried previously without effect—but her temperature rose to 104° F., and she died within forty-eight hours.

A few hours before she died I was informed that facts had just come to light showing that she had recently given birth to a full-time child which had just been discovered in an advanced state of decomposition in her trunk.

Such a state of things had not been suspected in any way, as she was afterwards proved to have given birth to the child without disturbing any one in the house, and to have performed her usual duties on the following day. She was also known to have bicycled about the country three days later.

Necropsy.

At the subsequent *post-mortem* examination very little positive evidence as to the nature of her disease was forthcoming. Rigor mortis was present in both lower limbs, but the back, upper limbs, and the head and neck were not affected.

The breasts were not noticeably enlarged, but milk could be expressed from the nipples. The nipples themselves afforded evidence of pregnancy, and the uterus was soft, enlarged, and typical of the third to fourth week after parturition. Internally, on the posterior wall of the fundus, was a small amount of soft, friable, purulent material, which, when examined bacteriologically for the presence of tetanus bacilli, proved negative. Both lungs were congested. The heart was in the state of systole, and contained a little fluid blood. The blood throughout the body was quite fluid. The bladder was contracted and empty. The brain and spinal cord showed no lesions, and beyond a few petechial hæmorrhages in the membranes of the cerebro-spinal system, and a curious "crimson lake" colour of the muscles generally, nothing further could be discovered.

Dr. Krater's experiments have demonstrated that strychnine is eliminated from the body by the kidneys within forty-eight hours, and as she had been under close observation for three days it was not thought advisable to have the viscera examined chemically.

The diagnosis in this case seems to lie between the poisons of strychnine and tetanus. Other conditions giving rise to similar spasms are tetany, lesions of the spinal cord or brain, hydrophobia and hysteria. Of these the last may, I think, be dismissed at once, as there was no evidence of hysteria in the girl's previous history, and her conduct at the time of her confinement was so cool and collected as to render the presence of such a condition extremely unlikely. Hydrophobia is disposed of by the history, by the presence of trismus and opisthotonos and by the absence of respiratory involvement.

Cerebro-spinal affections are put out of court by the presence of trismus, and the absence *post-mortem* of any pathological lesions in the nervous system.

Further, there were no other symptoms pointing to a cerebral lesion.

Tetany is more difficult to exclude, but the fact that her hands were not seriously involved, and that there were no complete intermissions of the spasms, are decidedly against it.

We are left, then, to decide between tetanus and strychnine, and I have tabulated the main symptoms, with reference to the way in which they favour one or the other.

Taking these in order:

Absence of a Wound.

There was no history of any wound, nor was any abrasion of the skin discoverable at the *post-mortem* examination.

On the other hand there was the purulent condition of the involuting uterus. Parturition must have taken place under conditions the reverse of aseptic. The fact that no

Patient's Symptoms.	In favour of Tetanus.	In favour of Strychnine Poisoning.
1. No history of any wound, absence of tetanus bacilli	No	—
2. No history of any poison having been taken	—	No.
3. Slow onset; prolonged course of disease (ten days)	Yes	No.
4. Early trismus	Yes	No.
5. Facial expression; risus sardonius absent	No	Yes.
6. Opisthotonos	Yes	Yes.
7. Muscles of abdomen unaffected	No	No.
8. Arms and hands unaffected	No	Yes.
9. Legs unaffected	No	No.
10. Persistent rigidity	Yes	No.
11. Lack of pain	No	No.
12. High temperature	Yes	Doubtful.
13. Absence of complete rigor mortis, especially of back	—	No.

tetanic organisms were found is not a matter of much importance, as it is comparatively common for those organisms to be absent from the seat of infection forty-eight hours after the onset of the disease.

Ingestion of Strychnine.

There was certainly no evidence that strychnine had been administered, but the circumstances of the case were such as to lead one to imagine that this state of affairs was extremely probable.

The first two points are therefore rather against tetanus

The Slow Onset.

The slow onset would fit in very well with the diagnosis of tetanus, and would be correspondingly against that of strychnine. I believe that the longest recorded incubation period between the ingestion of strychnine and the onset of the symptoms was in Dr. Macredy's case, where the time which elapsed was eight hours, and in this case laudanum had been taken at the same time as the strychnine. In these cases, however, there was a definite attempt to commit murder or suicide, or else the poison was taken accidentally, and in every instance fairly large quantities of the poison were taken. Is it not within the bounds of possibility that this girl had been taking strychnine in minute quantities for some time, perhaps with a view to the induction of abortion, and that some form of cumulative action took place, giving rise to quite atypical and prolonged symptoms?

Against this, however, is the fact of the rapid excretion of strychnine in the urine, and the impossibility of her having obtained further supplies of the drug while in hospital. Also, presuming that the drug was taken to induce abortion, she could not have taken any further doses for a fortnight before her symptoms appeared.

Trismus and Risus Sardonius.

The jaws were affected from the beginning, in marked contrast to strychnine poisoning, where the masseters are among the last muscles to be affected. The contraction of the jaws was not typical, as they were both actively and passively movable to the extent of a quarter of an inch.

Risus sardonius, supposed to be one of the most constant symptoms of tetanus, was entirely absent in this case from first to last.

Opisthotonos.

This is equally well marked in both diseases, though perhaps rather more violent in strychnine poisoning. In this case it was present but not to excess.

Contractions of Muscles.

The abdominal muscles were quite lax and unaffected throughout, and the lower limbs were but slightly involved. This condition would seem to be equally rare in both diseases.

The fact that the arms and hands were more or less involved is distinctly in favour of strychnine.

A point which was specially noticeable was that outside influences, noises, jars, movements of the bed, bright light, etc., had no effect whatsoever in causing or increasing the intensity of the spasms.

Persistent Rigidity.

The persistent rigidity and partial relaxation from time to time point strongly to a chronic variety of tetanus.

Pain and Temperature.

The absence of all acute pain, even during the severe exacerbations of the spasms, seems to be quite an unusual feature.

A high temperature used to be thought diagnostic of tetanus, but more recent researches have shown that strychnine poisoning gives rise to high temperatures as well. In both diseases the temperature is apt to rise in a marked degree after death. The presence of this *post-mortem* rise was not ascertained here.

Rigor Mortis.

In strychnine poisoning the back especially is generally rigid for a long time after death, and in a certain famous case it was found to be so two months after. It has, however, been known to pass off after twenty-four hours. It is usually present very shortly after death.

On the whole the balance of evidence seems to be slightly in favour of a chronic form of tetanus. The case was a remarkable one, for the balance between the two conditions, especially when she was first seen, was so evenly adjusted that each slight alteration in her symptoms seemed to incline it first in one direction and then in the other.

As time went on it became increasingly difficult to entertain the idea that the case was one of strychnine poisoning, especially when one considered that the duration of such a case from the onset of the symptoms averages two hours.

But even supposing that the spasms were due to a chronic form of tetanus, many of the symptoms still remain to be accounted for in some other way.

I am indebted to Dr. Francis Hawkins, under whose care the patient was in this hospital, for the permission to publish these notes.

PRELIMINARY NOTE ON THE HISTOLOGY OF EGYPTIAN MUMMIES.

By MARC ARMAND RUFFER, M.D.,

ALEXANDRIA.

SOME time ago my friend Professor Elliot Smith, F.R.S., gave me some fragments of mummies of the XXI dynasty (dating from 1000-1050 B.C.), and I endeavoured to examine these fragments by histological methods. As far as I knew then, this was practically the first attempt to study microscopically the minute structure of tissues mummified for about three thousand years; at any rate, I found nothing bearing on this subject in the literature at my disposal, but I was informed that Professor Looss of Cairo had shown the striation of mummified muscular fibres to his colleagues. I demonstrated some of my sections at the Sheffield meeting of the British Medical Association and at the December meeting (1908) of the Cairo Scientific Club. Quite lately my friend Mr. Shattock has read a paper on a similar subject before the Royal Society of Medicine.

METHOD.

It was found impossible to obtain good microscopical sections without first restoring, to some extent at any rate, their flexibility to the tissues, as their brittleness and hardness broke the edge of the microtome knives; even when a fair section was obtained, this invariably crumbled up when transferred to the slide. I need not describe the various methods tried and rejected, but it will be sufficient to note that, by combining an alkaline salt such as carbonate of soda with a hardening reagent such as alcohol or formol, the mummified tissue placed in the mixture gradually swells up and resumes its former shape.

The solution which has given me the best results is composed of alcohol 100 parts, water 150 parts, 5 per cent. carbonate of soda solution 60 parts. In many cases, however, such a solution softens the tissues too much, and more alcohol must then be added.

After a period of time, the length of which depends on the bulk and nature of the tissue, the solution is replaced by 30 per cent. alcohol, and more alcohol is added day by day. After two or three days the softened tissue is transferred to absolute alcohol, then chloroform, paraffin, and cut *secundum artem*. During these manipulations the tissue remains pliable, though it shrinks a good deal. Very thin sections do not present any particular advantages, and I generally use three divisions of Minot's microtome. Such preparations stain readily with the ordinary dyes, but for tissues such as muscular fibre teased preparations, after maceration in 1 in 10,000 caustic potash, give excellent pictures.

RESULTS.

I have prepared sections of muscle (voluntary, cardiac, and involuntary), blood vessels, skin, intestine, stomach, liver, kidney, bone, mammary glands and testicles, and the main characters of all these organs and tissues can be readily recognized. The striation of muscular fibre, for instance, the muscular coats, the submucous tissue, and occasionally even the glands of the intestines and the convoluted tubules, the straight tubules and glomeruli of the kidneys, the various layers of the skin can be identified with certainty. I have no doubt that coarse pathological changes, such as inflammation, cirrhosis, tubercle, or cancer, could be demonstrated by this method.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

NUTMEG POISONING.

NUTMEG poisoning itself is rare, and this case is especially interesting in that, although the amount taken was so small, it led to very definite symptoms and also to my hearing of two similar cases. I was sent for to see a man, aged 22, who had suddenly been taken ill after a midday meal of cold mutton and milk pudding. The pudding was a small one and he had eaten the whole of it himself. It was flavoured with about a quarter of a moderately-sized nutmeg. Within a few minutes he felt his face flush and he began to itch all over and went up to his bedroom. Here he was immediately sick and vomited his dinner, and at the same time his nose began to bleed. He then lay down on his bed and did not remember anything more till I roused him. I saw him about half an hour later. He was lying face downwards on the bed in a completely collapsed condition. His face was swollen, especially his lips and lower eyelids, and he was cold and markedly cyanosed. The pupils were contracted, but not pin-point. The radial pulse was rapid and scarcely palpable; the heart was thumping and irregular. On speaking to him he appeared dazed, but was able to give me a clear description of what had happened. His tongue was clean, slightly swollen, and he complained of a feeling of fullness in his throat. He also had some slight abdominal pain, but this soon passed off. About an hour later the cyanosis had disappeared and was replaced by a diffuse flush. His face was still swollen, and he still complained of slight itching. The pupils were now normal. There was no further vomiting, and beyond a feeling of drowsiness there were no further symptoms, and he awoke the next morning feeling perfectly well. The vomit obviously consisted of his dinner in an undigested condition. It did not smell of nutmeg. Careful inquiry elicited no other cause for what was evidently a case of acute poisoning. The patient was a healthy, well-developed youth.

The two other cases were described to me by his mother, a publican's wife. Some years ago two barmaids in her employ were awakened at night with abdominal pains, vomiting, and diarrhoea. Their faces were noticed to be swollen and blue. On going to bed they had each taken half a nutmeg in a glass of stout, as they had been assured that this would cure a rash they had. They recovered without further symptoms.

Holnedale, Parkstone.

K. MAYOR GIBBINS.

MÈNIÈRE'S DISEASE.

I READ with much interest the able paper by Dr. W. Syme, in the JOURNAL of April 10th, on aural vertigo. May I mention a few points noted in a personal attack, and gathered from cases that have come under my care?

Under the term "Mènière's disease" is grouped a class of cases, rare in occurrence and unique in character, in which vertigo is caused by perversion or abeyance of the labyrinthine function, the cause of which may be either of an irritative or destructive character, whilst there is always present coincident disease of the semicircular canals.

The vertigo occurring in Mènière's disease is its most prominent symptom, and is of a functional character, and may show itself in a person seemingly in good health, or the subject only of some slight neglected auditory disease. He finds he has a noise in one of his ears, and suddenly becomes giddy. Surrounding objects appear to be revolving; if in a room there may be a sensation as of walls and ceiling falling in upon him, or he may feel that he is going through movements of gyration, which have been compared to the sensation caused by long-continued rotary movements of the body. If the vertigo be slight, the patient may be able to walk unsteadily; if in a greater degree, walking is impossible, associated with inability to stand without support. In a severe attack the patient falls, or rather is suddenly thrown to the ground. If in bed when the attack comes on he may complain of the bed rising or sinking, or of rotation. There is no loss of consciousness, except, perhaps, momentarily in severe cases; nor do the facial or other muscles show any muscular spasm. In one of my patients, if sitting, the legs were thrown out violently, and the hands became blanched—the latter condition due possibly to some disturbance of the inferior cervical ganglion and brachial plexus. The attack is followed by a feeling of extreme prostration. The paroxysm may only last a few moments, may recur many times a day, or only at rare intervals. Tinnitus is commonly persistent, and before the onset of the attack may be found to be increased.

The mental anxiety is no doubt a reflex condition, and is often most persistent and distressing; the patient may be afraid to walk across the street, or to be left alone, although the general health may be good and a long time may have elapsed since an attack; this state of apprehension of a recurrence of the attack may last for months or even years. Successive attacks may recur at variable intervals, depending largely on the recurrence of any of its causes.

Common to the majority of cases will be found three cardinal associated symptoms—vertigo, tinnitus, and deafness. Vomiting may be present, but is not constant.

I think it may be granted that most of the cases seen are the result of some congestive or inflammatory derangement of the auditory nerve, usually of the nerve terminals of the labyrinth; if due to this condition, on placing a watch on the affected mastoid, it will be heard very imperfectly, or not at all, and, further, that all cases of functional vertigo are not cases of *vertigo ab auro laesa*.

Deafness, to a greater or less extent, is constant, but not an essential symptom. Clinically, we find a certain proportion of cases occurring in subjects with normal auditory conditions; when present, the deafness is in the internal ear, and as the deafness increases the tendency appears for the patient to improve. My experience leads me to agree with Trouseau, who called this affection stomachic vertigo—*vertigo a stomacho laeso*—that dyspepsia plays an important part in many of the cases seen. Gout and influenza are also well-known qualities in its production, particularly in patients where there may be overtaxing of the mental faculties and anxiety of mind.

With regard to treatment, we must endeavour to remove the exciting cause, be it gastric, gout, or neurasthenia. I avoid quinine and sodium salicylate owing to their well-known sequelae: I consider strychnine the remedy *par excellence*, alone or given in conjunction with dilute hydrobromic acid, with counter-irritation behind the ear by a stimulating liniment or blister, followed later by galvanism. In an obstinate case, on the advice of my friend the late Mr. H. Bendelack Hewitson, a seton was introduced behind the ear, and worn for some time with success. Irritating and painful as the wearing of a seton is, I should certainly recommend its trial before advising the more

radical operation of destroying the labyrinth, which should only be carried out as a last resource.

J. FLETCHER HORNE, M.D. St. And., F.R.S.E.,
Honorary Consulting Surgeon, Beckett Hospital, Barnsley.

MAMMARY CANCER RECURRING SIXTEEN YEARS AFTER OPERATION.

WITH reference to Dr. D. McNeill's case of mammary cancer recurring and causing death fourteen years after the primary operation (page 841), I lately lost a patient from the same cause, on whom the original operation was performed on October 9th, 1891; her death, from recurrence, took place at the age of 55, on June 11th, 1908, sixteen years and eight months! In my case subsidiary operations were performed in 1895, 1897, and 1898.

APPARENT UNILATERAL DEVELOPMENT OF THE MAMMA
IN THE MALE.

(By JOSEPH H. WHELAN, M.D., R.N. (ret.),
Medical Superintendent.)

C. A., aged 26, A.B., a bright, intelligent Swede, presented himself at the hospital on February 18th, 1909, with a well-developed, apparently female type of breast on the left side, well shown in the photograph. He stated that eight years previously it was much the same as that on the right side, which is the usual rudimentary male organ. Since then—that is, practically during his sexual life—it had gradually and painlessly enlarged symmetrically. The areola was large and the nipple prominent. He said that he had felt no subjective sensations in the latter at any time, that it was not erectile, though at times it exuded a clear fluid; but he was naturally reticent on the subject of his peculiarity. He was very desirous to have the organ removed, as it was the cause of unpleasant attentions from his comrades on board ship. In other respects he was entirely a well-developed male.

On February 24th I removed the breast, which weighed in the fresh state just under ½ lb. It was perfect in form and appearance.

I sent the specimen to Professor David Hepburn, F.R.S. Edin., of the University College, Cardiff, who took a great interest in the case from an anatomist's point of view. The following was found on dissection: The superficial surface of the specimen was covered by subcutaneous fat, and on removing this layer it presented a convex surface with depressions suggesting lobulation, spreading from the nipple as a centre. The deep surface was smooth and fairly flat. On section the naked eye detected no appearance of cysts, and the colour of the mass was uniformly white. By the microscope the tissue was simple fibrous material, but scattered through it were dilated ducts lined by nucleated epithelium. It had been hardened and preserved in strong formalin solution.

Mr. W. COATES, President, in the Chair.

Excision in Suppurative Arteritis.

MR. J. E. PIATT related the case of a boy aged 4 years, admitted to the Royal Infirmary with a very extensive deep cellulitis of the forearm. Incisions were made on the day of admission, but two days later haemorrhage occurred and the brachial artery was tied. Eight days afterwards haemorrhage again occurred, and it was therefore decided to open up the wounds and search for the bleeding vessel. The upper part of the radial artery was found to be in a sloughy condition, and 2 in. of the vessel were removed, the divided ends being ligatured with catgut. The patient, although greatly exhausted at the time of operation, afterwards recovered well and the functional use of the arm was perfect. In a similar case which he brought before the Society fifteen years previously he had removed 4 in. of a sloughing brachial artery with complete success, the patient making a perfect recovery. He pointed out that this method of treatment was merely an extension of the ordinary rule for the treatment of secondary haemorrhage—namely, dealing with the vessel at the site of the bleeding—and that in the cases mentioned it was the only alternative to amputation of the limb. The method was more likely to be of use in the case of the arm than of the leg, owing to the freer collateral circulation.

Radiography of the Kidneys.

DR. W. J. S. BYTHELL, in a paper upon the radiography of renal and ureteral calculi, gave examples to show the advances made in x-ray work, whereby it was possible to distinguish the size and structure of the kidney itself, and thus to a large extent make out the pathological condition of that organ. Such cases included several of pyonephrosis and tuberculous kidney.

Chronic Alcoholism.

DR. GEORGE ASHTON, in a communication on the hypodermic injection of atropine and strychnine in chronic alcoholism, said he had tried this treatment in three cases, all confirmed alcoholics. The solution used was a mixture of liq. atropin. sulph. and liq. strychnin. hydro. in the proportion of 1 to 4. Five minims of this solution were injected twice daily into the outer surface of the calf of the leg. The first patient had seventy injections, the second had thirty-four injections, and the third thirty injections. The general health was considerably improved, but the underlying disease—the craving for alcohol—was unaffected. His patients strongly objected to the repeated pain of the injections and to the dryness of the mouth, caused by the atropine. He had reluctantly come to the conclusion that the treatment was absolutely useless.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Sir PATRICK MANSON, K.C.M.G., President, in the Chair.

Beri-Beri: The Etiology of Beri-Beri.

A PAPER on beri-beri was read on behalf of Dr. L. BRADDON, of the Federated Malay States, who showed that the first noticeable fact in the etiology of the disease was that it attacked only rice eaters, and next claimed that only those were attacked who ate rice of a certain kind. If rice was husked, and allowed to remain lying in bags, it developed a poison which induced beri-beri. Tamils, of whom there were over 150,000 in British Malaya, never suffered from beri-beri, and this immunity he believed to be due to the fact that the rice they used—their staple article of food—was treated in a different way. While in the husk the rice was "cured" or parboiled and dried, and he believed that in this way the development of the noxious agent was prevented. In the endemic area 97½ per cent. of all cases of beri-beri occurred in

Chinese, who always ate uncured rice. Fletcher had shown at the Selangor Lunatic Asylum that of 120 lunatics who were fed on uncured rice 43 developed beri-beri, while of 140 who were fed on cured rice only 2 were affected. Still more conclusive were the experiments which had been carried out at Durian Tikus by the officers of the Federated Malay States Research Institute. A working party of 300 men were divided into two groups; half were fed on cured rice for a year, and half were fed on uncured rice for a year. Of the former none were affected; amongst the latter beri-beri was very prevalent. The diets were then reversed, with the consequence that those who had been free before were now attacked, and vice versa. Moreover, by moving the groups of labourers about the element of place infection was excluded. Not only was cured rice a preventive of the disease, but it was a powerful remedy for beri-beri when once established; and in the Singapore Lunatic Asylum, and in other places in Malaya, they had excellent results from this treatment. Fresh rice—newly husked rice—was innocuous, and this he thought indicated that when the husk was removed after some time an epiphyte developed on the outside of the grain and generated a nerve toxin. The conditions which had been described as beri-beri in non-rice eaters were not clinically allied to the beri-beri of the Eastern tropics; in uncured rice which had been husked for some time would be found the true cause of the disease.

A paper on the same subject was read for Dr. A. R. WELLINGTON of Sarawak. It detailed his observations in the mining and agricultural districts of that Dependency. He had carefully examined the theory that bed-bugs were carriers of infection, but he had been unable to find much evidence in support of that view, or, indeed, of any other theory of parasitic infection. Nevertheless, since bed-bugs in the General Hospital at Kuching had been exterminated, there had been no fresh cases there. Beri-beri was unknown amongst the Dyaks in their own country—the interior of Borneo—but if they came to Sarawak, they suffered as much as the Chinese. In Simanggang Gaol and in Baram the disease had been checked by feeding the inmates on fresh rice. On the other hand, at Brooketon coal mines, beri-beri was at one time rampant. Now there was none, although no change had been made in the rice which was used; this experience had been repeated in many instances, notably at Poak and at the Bidil Mines. Instances of apparent infection, mediate or contact, had been noted, and examples were given. There were also instances in which place infection seemed to be the predominant factor.

DR. CARNEGIE BROWN said that the theory that beri-beri was caused by some alteration in rice had been frequently investigated—especially in Japan—and had been rejected on the grounds that no change could be detected in the rice, and that it was not in accord with clinical facts. These conclusions, however, possibly went too far. Beri-beri had been eradicated from the Japanese navy by general sanitary measures and by the addition of considerable quantities of animal food to the dietary, and there had been no special treatment of the rice ration, which was still issued; but its amount must have been decreased, and Dr. Braddon's argument of diminished toxin was a reasonable one. Among the difficulties in the way of the rice theory were, first, that a disease indistinguishable from beri-beri was often seen in persons of whose diet rice formed no part; and, secondly, that the incriminated rice was the principal food of large communities who lived in the endemic area, and never suffered from the disease. The evidence supplied by asylum neuritis, ship beri-beri, and similar conditions could not be lightly brushed aside by the affirmation that they were not beri-beri. In Italian sailing ships, where rice was largely eaten, beri-beri was unknown; in Norwegian ships, where rice was never consumed, and the sailors preferred rye and wheaten bread to anything else, the disease was so common that a commission had been appointed to report on its prevalence. The most prominent clinical feature of beri-beri was that it was a disease of association. In the districts and towns with which Dr. Braddon dealt there were thousands of Chinese households who lived all their lives on the rice which was said to engender beri-beri, and

yet, so long as home life continued, not one member of the family was attacked by the disease. On the other hand, if a man from one of these houses went to work on a mine, or if he had the misfortune to get into gaol, or into an asylum or hospital, he was extremely likely to acquire beri-beri. The feeding experiments which had been detailed so clearly by Dr. Braddon were, however, very striking.

Colonel LEISMAN said that personally he had always been inclined to think that the epidemiology and the clinical features favoured the idea of protozoal infection, but the most careful researches appeared to furnish no support of this theory. Meantime there was good reason to think that there was some connexion between beri-beri and rice, and he believed that at some future time the association would be proved.

Dr. JAMES MAXWELL (Formosa) said that in that country they had a certain percentage of beri-beri, although the people lived in their own houses, and always husked their rice as they wanted it.

Dr. G. C. LOW thought that ship beri-beri could not be separated from tropical beri-beri. It was certainly not scurvy, and he fully believed that it was identical with the beri-beri of which Dr. Braddon spoke.

Dr. T. S. KERR said that since husked rice had been introduced into the asylums and hospitals of the Straits Settlements there had been no fresh cases of beri-beri amongst patients admitted for other diseases.

Sir PATRICK MANSON said that Dr. Braddon's theory was supported by a strong array of figures and facts; it was not, however, quite complete. One incident looked as if the infection was place-infection and independent of the diet. The questions raised were so important that the discussion would be continued at the next meeting.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DISEASES IN CHILDREN.

At a meeting on March 26th, Dr. E. CAUTLEY in the chair, Mr. MACLEOD YEARSLEY showed a case of *Word-deafness* successfully treated. Originally the child could not appreciate heard speech, which she merely repeated aloud; when, however, she was able to see the speaker, and lip-read, the speech was immediately answered rationally. The word-deafness apparently prevented the higher centre being effective. After long practice heard phrases were now understood and answered without the motor response of repeating the question. The exhibitor thought it difficult to explain the case on any hypothesis other than that of weakness of the auditory centres. Dr. EDMUND CAUTLEY showed the brain from a case of *Cerebral diplegic spasticity*, which had been shown to the Section on February 20th, 1909. The whole of the frontal and parietal regions was converted into a bilateral cystic form, bounded medially by a wall containing a moderate amount of brain substance. According to the history, the child had been healthy till the age of 7 weeks, and then had an illness which could be accounted for as encephalitis or meningitis. The *post-mortem* appearance made it more probable that the condition was congenital and dependent on developmental error in the prosencephalon. Dr. LANGMEAD said that there was a specimen in the museum of Great Ormond Street Hospital which closely resembled the case. It showed some narrowing of the small cerebral vessels. Dr. G. CARPENTER said he had neither seen nor read of a case like it, but had seen a lobular cystic condition, which Dr. Ernest Jones reported was, in his opinion, syphilitic. During life the child had been spastic, with head retraction, and showed atrophic patches in its choroid. Dr. WHIPHAM showed a case of *Transposition of the viscera* in a girl aged 6. There was a mitral systolic murmur at the heart's apex. The child had had chorea twice. The CHAIRMAN thought that such cases were not so uncommon as one was led to believe in books. He believed that prognosis of life was just as good as if the heart were not transposed. Dr. F. J. POYNTON and Dr. LANGMEAD thought that if the heart was on the right side of the body there was greater liability to endocarditis. Dr. PARKES WEBER asked whether proposers for life assurance should be rated up if the viscera were transposed. Dr. WHIPHAM thought not. Dr. PARKES WEBER referred to cases in which several children of the same parents had had jaundice, some of

them having died. Dr. PORTER PARKINSON read a paper upon three cases of *Henoch's purpura*. In Case i the patient, a boy aged 8, was treated with two injections of horse serum without any improvement; he eventually recovered, but when discharged the urine was still albuminous. In Case ii the treatment was at first calcium chloride, and later three injections of horse serum. Two fresh groups of purpuric spots appeared while the child was taking calcium. In Case iii, a boy aged 6, as the abdomen became distended, it was thought that intussusception might be present. The abdomen was opened, but none found. The diagnosis then lay between measles and Henoch's purpura. The exhibitor inclined to the latter diagnosis, but the absence of blood and albumen in the urine was unusual. The case supported a suggestion of Mr. Hugh Lett that it was advisable not to operate for intussusception in a case of Henoch's purpura unless an abdominal tumour could be felt. Mr. HUGH LETT said the presence or absence of intussusception in Henoch's purpura was very important. He had reported a case in which intussusception had developed during the illness, and was reduced by operation. Seventeen days later another intussusception occurred, and the child died. He thought that the crucial feature to be relied upon was the presence of a sausage-shaped tumour, and that there should be no operation where a tumour was not felt. He had operated upon 23 cases of intussusception, in all of which he felt a tumour either from the abdomen or per rectum. In two or three of them he could not feel it without an anaesthetic. Surgical operation in Henoch's purpura was a very serious matter, and in some cases the patient had died of haemorrhage from the wound. If he saw another case of undoubted intussusception with purpura, he would be inclined to try injection before operation. Dr. LANGMEAD said that a tumour might be present simulating intussusception, but due to extravasation of blood; and Dr. E. I. SPRIGGS referred to another case showing this condition. The CHAIRMAN thought the term "*Henoch's purpura*" should be dropped, as the disease was simply purpura haemorrhagica with abdominal symptoms; and Dr. PERNET agreed.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

At a meeting on April 6th, Dr. BURTON BROWN, President in the chair, Dr. GORDON SHARP, in a paper on *Heart tonics*, said that almost the only way of judging of the effects of digitalis or other heart tonic was an indirect one—namely, by observing whether the drug would remove a cardiac dropsy after rest in bed and nursing had failed. To credit any substance as a heart tonic because it appeared to tone up the pulse, lessen the area of heart dullness, or relieve palpitation was evidence of an uncertain kind, because there was room for so much divergence of opinion on these points. Digitalis acted much more quickly than was generally supposed. The tincture was the handiest preparation. If rejected the drug could be given in pill form. It acted quickest when it was given in doses as large as could be tolerated. Digitalis was the only real heart tonic. The diuretic action of strophanthus seemed to be direct, namely, on the secretory tubules of the kidney, as opposed to the indirect diuretic action of digitalis (and in part so in squill) through the circulation. Although it did not act in cardiac dropsy like digitalis it might by its stimulant action on the kidneys produce a certain amount of diuresis. Given in 20 to 30 minims doses of the tincture, it had in many cases of cardiac dropsy a general analgesic action but no effect on the dropsy. It gave comfort to the patient.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

At a meeting on April 2nd, Dr. E. H. TWEEDY, President, in the chair, Dr. PIERCEY showed a small uterus removed for *Recurrent haemorrhage* from a patient, aged 50, the mother of some children. She had been curetted in the first instance, and some thickened membrane had been removed. Some improvement was made, but the haemorrhage recurred. Atrocousis was applied, but after another violent recurrence the uterus was removed. The specimen showed enormously thickened uterine walls, and

the position of the endometrium indicated in section by a thin line showing almost complete absence of endometrium. Dr. HOLMES recalled a case of Sir Arthur Macan's in which the hæmorrhage recurred after atmocausis and hysterectomy was performed. The vessels of the uterus were distinctly atheromatous, and it was doubtful if atmocausis would cure in such a condition. Dr. JELLETT expressed great doubt as to the value of atmocausis in cases in which there was no endometrium. The hæmorrhages apparently came from blood vessels more or less diseased, and the superficial effect of atmocausis could not be permanent. He did not see how a second application of atmocausis would produce more than a temporary result, as in the first application. He thought there was nothing left in such cases but hysterectomy. Sir WILLIAM SMYLY said he saw a great theoretical difference between atmocausis and curetting. In the latter they removed the thickened membrane, and hoped that healthy membrane would grow. If not, they had to curette again. Atmocausis, however, destroyed the membrane and tissues of the uterus, and the depth of the slough depended on the heat of the steam and the duration of the application. If they did not get a sufficient slough the first time, they had to repeat the application. In an old woman the obliteration of the uterus, which atmocausis was apt to cause, was desirable. He thought it was a very good method, and it was not so severe as hysterectomy. Professor ALFRED SMITH said the effect of atmocausis was rather speculative, and in the great majority of cases they would find the best treatment to be removal. The President said that in two cases he "atmocaused" two young women twice each, after they had been curetted ineffectively. The atmocausis failed on the first application and succeeded on the second in each case. He seldom "atmocaused" for more than fifteen seconds. It was better to do too little than too much, and on the second occasion they might give twenty seconds with better results.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.—At a meeting on April 6th, Dr. MAY THORNE in the chair, Dr. JULIAS HAMILTON spoke of the value of *Open-air professions for women* physically unable to earn their living in towns. As warden of a horticultural college she had noticed that delicate women improved enormously in health even after one term's work. She considered that horticulture in all its branches was very suitable as a profession for women suffering from weak eyes, bronchitis, dyspepsia, and various nervous complaints, and as the demand for women gardeners was much greater than the supply, they could be sure of earning a living when their training was completed. Miss SHEPPARD opened a discussion on *The examination of the eye in school children* by relating some of the early history of the movement. Several years ago she had examined the eyes of about 1,000 children in a school at Whitechapel, and found that about 33 per cent. had serious defects. The first effort at systematic examination of all children of school age was made in 1902 by the London School Board, who appointed six medical officers for that purpose. Miss LENEY said that she had examined 7,600 children, and found that 70 per cent. had some eye defect—generally an error of refraction; 5 per cent. had some external disease of the eye, and 2½ per cent. suffered from strabismus. Miss ROBERTS gave an account of the unsatisfactory condition existing in the large majority of the London schools at the present time. In Standards i to iv the teacher examined the vision, taking both eyes together, so that if one eye were blind this might not be discovered until the child reached the higher standards. If the vision were less than $\frac{6}{6}$ the child was examined by the medical officer, who also examined Standards v to vii. Even with this method about 10 per cent. of the children were found to have serious defects; only about one-half were treated, but now the Children's Bill had come into force an improvement might be hoped for in this respect. Miss MOFFATT commented on the difficulty of obtaining treatment for children in the country, where expense was incurred in taking them to the nearest hospital town. Miss THORNETT remarked that many of the slighter cases of defective vision depended on ill health due to the wretched conditions under which the children lived; in many cases fresh air was more needed than spectacles.

Rebiews.

OPHTHALMOLOGY.

THE charge is frequently brought against those who confine themselves to one particular line of practice that they look upon their patients as if they consisted solely of the particular part or organ to which they direct their special study, and there is no doubt that this charge is sometimes justified. The most successful practitioner is he who can take a broad-minded view of the condition of the patient himself, and who uses all the information he can gather for his patient's benefit. Possibly ophthalmic surgeons, whose domain in practice is so small an organ, are sometimes apt to overlook the underlying constitutional causes of some ocular manifestations of disease, and in order to prevent any one falling into such an error we cannot do better than commend to ophthalmic surgeons an excellent little book by Dr. MAITLAND RAMSAY on *Diatheasis and Ocular Disease*.¹ Three chief diatheses claim attention—the neurotic, the scrofulous, and the arthritic. The description of these three types is most lifelike, and when reading these interesting chapters, it is easy to conjure up in one's mind the exact type of person described. Take the neurotic diathesis for example:

Of spare build, restless and unwearied, with a mind so active that it allows neither him nor his immediate circle any repose, he feels pain very acutely, and consequently what may in reality be a very trifling ailment assumes to him very serious proportions. His nerves overdeveloped, tyrannize over his body, and his excellent memory makes him a terror to the young practitioner, whom he never allows to forget anything he may have told him.

How true to life is this description, which is quoted only as an example of the graphic manner in which the author portrays his types. The condition of the eyes is next described, Chapter V dealing with inflammation of the conjunctiva and sclerotic, and Chapter VI with inflammation of the uveal tract; here the author has a wide field, and discusses the various abnormal states of the system which give rise to iritis and choroiditis; kidney disease and glycosuria are considered in dealing with inflammations of the retina and optic nerve. With regard to toxic amblyopia and retrobulbar neuritis, the author does not look upon tobacco and alcohol as being so much the actual cause of the disease as rather causes of defective metabolism and excretion of the toxic products; in support of this view he cites the case of a woman aged 45 who had never smoked nor taken alcohol, and yet who had all the symptoms of toxic amblyopia with gouty iritis later on; she was of the sanguine arthritic diathesis, and quite recovered with careful dieting and an antigout treatment. This case tends to confirm the treatment of toxic amblyopia recommended by Charles Wray, who makes his patients drink large quantities of water and take a good deal of exercise; by these means he has even cured patients who would not give up tobacco, though those who will give it up and carry out the treatment are cured in a quarter of the time; Dr. Maitland Ramsay lays great stress on the condition of the urine which always contains oxalic acid crystals and an excess of urates. The final chapter, on glaucoma, contains some very sound advice for the general practitioner and for the ophthalmic surgeon. The book, like others by the same author, is lavishly illustrated. Several of the pictures are taken from his *Atlas of External Diseases of the Eye*, and all of them are produced as plates, of which there are seventeen. The book is well worth reading and studying; it is really original and calls attention to an aspect of ophthalmology which is only too frequently neglected to the great detriment of the patient.

Professor AXENFELD of Freiberg has so recently been the honoured guest of our Association that any work issued under his direction has for us a special interest. His new textbook² is a symposium, the various chapters,

¹ *Diatheasis and Ocular Disease*. By A. Maitland Ramsay, M.D., Ophthalmic Surgeon to the Glasgow Royal Infirmary, etc. London: Baillière, Tindall, and Cox. 1909. (Cr. 8vo, pp. 132; plates IV, 3s. 6d.)
² *Lehrbuch der Augenheilkunde*. Herausgegeben von Theodor Axenfeld. Jena: Gustav Fischer. 1909. (Sup. roy. 8vo, pp. 694. Brochüert M.14, gebunden M.15.)

written by eleven professors, being addressed not to the specialist, but to the general practitioner and the student. The work begins with a good account of therapeutic methods, by Axenfeld, who also writes the second chapter, on the objective examination of the eye. This subject is treated in a clear, masterly manner, and the chapter contains many hints and minutiae which the student is rarely taught and has generally to learn by experience. Ophthalmoscopic diagnosis, by Flschmig, is excellent, especially when he discusses and explains the various appearances seen at the nerve entrance—a subject to which he has given great attention—but the plates are very poor; that of the normal fundus is, perhaps, one of the worst, the macula being shown as a dark-brown oval surrounded by a white mass of exudate. In the chapter on subjective testing, by Heine, the elementary explanations of the optical properties of prisms and lenses, well known to every student, might have been omitted, and more space devoted to refraction, which is most inadequately treated. The cardinal value of retinoscopy is not insisted upon, nor are we told that this test can be carried out at arm's length as well as at a distance of over a metre. Lister's mirror, which greatly simplifies the process, seems to be unknown to the author. Maddox's rod is not mentioned, and Worth's work, which marks an epoch in our knowledge of squint, is barely alluded to. The statement that occlusion of the best eye to develop the vision of its fellow has been generally abandoned on account of the poor results obtained contains a double error: the method is being more and more widely used, and the results are often very good. Bielschowsky, who writes the chapter on squint and heterophoria, is obviously well acquainted with Worth's work; his views are diametrically opposed to Heine's, a curious example of divergent opinions in a book intended for the general reader! Von Hippel's description of trichiasis operations shows great want of practical experience; Waldhauer's operation, which always causes a secondary trichiasis, is praised, whereas the two best methods—van Millingen's and Snellen's—are not described. Nor do we imagine that any one else uses a keratome for these operations, as is shown in one of the diagrams. Schirmer not only gives elaborate instructions for slitting up the canaliculi and passing probes to cure dacryocystitis—an utterly obsolete, painful, and useless procedure—but states that the results of such treatment are very hopeful! The directions for extirpation of the sac are meagre and inadequate. We are advised to open a lacrymal abscess by an incision "at least 2 cm. long," and when the swelling has subsided not to excise the sac, but to use probes, and attempt to preserve it. Axenfeld on conjunctival disease constitutes a valuable monograph, and Flschmig treats corneal disease in a masterly fashion—in fact, all that is written by these two authors could hardly be improved. Krueckmann writes one of the best descriptions of iritis which we have ever read, while the highly artistic and yet accurate drawings make the condition very clear. But chronic irido-cyclitis is not mentioned, nor is oral sepsis alluded to as a frequent cause. We can find little or no information about central choroiditis; in fact, the important subject of macular disease receives very inadequate treatment. Operations are treated so badly that the subject had better have been omitted entirely: the directions are misleading, and the diagrams are in many cases poor. Perhaps the worst is Fig. 364; a cataract section is being made on a microphthalmic cornea with an almost blunt pointed knife. We are advised to make the incision 1 mm. from the horizontal diameter; this would often result in an unnecessarily large wound. Peters's chapter on glaucoma touches upon the theory of the disease but very inadequately. He still adheres to the notion that excavation is the result of pressure, and states that it is a slow process. He would appear to be unaware that Schnabel has seen total excavation of the disc develop in fourteen days. Taken as a whole, the book cannot be recommended as a guide to the inexperienced; it is very unequal, being in some parts really first class, in others mediocre or worse. In many respects the teaching is not in accord with modern practice, and many conditions are not even mentioned—as, for example, "retinitis pigmentosa albescentis." Many of the illustrations are most beautiful, and accurately show the disease, others indifferent, and some bad.

RETINAL HAEMORRHAGE.

THE monograph we have under review, which gives an account of the anatomical changes found in four eyes affected with retinal haemorrhages enucleated on account of secondary glaucoma, is a thesis for the degree of M.D. written and defended by Fraulien ANNA DAHLSTRÖM at the University of Upsala. The clinical material was obtained from, and the pathological work carried out in, Geheimerat Sattler's clinic at Leipzig. The thesis is illustrated by five plates of the most beautiful water-colour paintings of microscopical sections we have ever seen. They are perfect both as works of art and as clearly showing the changes described in the text.

The scope of the research is purely histological. The four eyes were hardened, imbedded, and cut in serial sections, and from a laborious and painstaking examination of the sections the pathological processes have been reconstructed. The author gives an exhaustive summary of the various theories which have been advanced to account for the onset of glaucoma, in which full justice is done to English ophthalmologists, including the recent work by Henderson of Nottingham. Each theory of glaucoma is criticized very fairly with reference to the changes found in the four eyes examined. For example, Miss Dahlström does not find the enlargement of the lens postulated by Priestley Smith to account for glaucoma. As far as the cause of the high tension found in these eyes can be explained by the result of a careful histological research it would appear to have been due to two factors: (1) An active hypersecretion from the diseased retinal vessels, and (2) an obliteration of the filtration angle, the result of senile changes, sclerosis of the ligamentum pectinatum, and in two at least of the eyes, due to the presence of iritis followed by extensive adhesion between the iris and lens capsule. But in no case were the histological evidences of irido-cyclitis very well marked.

The first cause suggested is open to the criticism that the classical researches of Leber and those of most modern investigators afford no confirmation whatever of the theory that any appreciable quantity of the interocular fluids transudes from the retina or choroid. The almost exclusive source is the ciliary body, which in the eyes examined was small and atrophic. But, in any case, the question is not of any great moment; for the examination of an eye which is extensively diseased, in which there are large haemorrhages and in which the high tension is only the final stage of a definite pathological history, cannot be expected to elucidate the difficult and obscure problem of the genesis of primary glaucoma. At present, no one hypothesis has been formulated which is entirely satisfactory and which accounts for all the observed facts. The truth probably is that many etiological factors are responsible for the disease, and that in any given case these factors participate to a greater or less extent. In one case a large lens may be the prominent feature, in another high blood pressure, associated with diseased arteries, may determine the onset of high tension.

SYPHILIS.

THE second volume of the *System of Syphilis* opens with a monograph by Mr. D'ARCY POWER on the surgery of syphilis, occupying 251 pages and illustrated by 35 plates, many of which are coloured. The title chosen must be taken in a wide sense, indeed as practically covering a great part of the field of syphilis. For it must not be forgotten that in this country syphilis was for a long time the appanage of the surgeon and was outside the province of the physician proper. Now that it is known, though frequently lost sight of, that the lues venerea is responsible for a large amount of visceral morbidity this monopoly no longer holds good. Mr. Power has confined himself to the parts of the organism which claim the attention of surgery, such as the bones, joints, teeth, rectum, and so forth. Altogether this part of the volume will well repay perusal. It will be remembered that a very complete historical account of syphilis appeared in Volume I, so that the

* *Anatomische Veränderungen in vier wegen Durchstichsneuritis exstirpierten Augen mit Neigung zum Glaucoma.* Von A. Dahlström. Leipzig: A. Edelmann, 1908. (Med. 8vo, pp. 148; Taf. v.)

† *Oxford Medical Publications. A System of Syphilis.* Edited by D'Arcy Power, M.B., F.R.C.S., and J. Keogh Murphy, M.D., M.R.C.S. London: H. Frowde, and Hodder and Stoughton, 1908. (Royal 8vo, pp. 395. Plates 35. 42s.)

historical survey which serves as an introduction to Mr. Power's article has led to some unnecessary overlapping. But it must readily be conceded that his short review makes very good reading. The unfortunate experiment of John Hunter is insisted on. This cannot be done too often, for such hasty generalizations as Hunter's based on limited evidence, however convincing it may appear to the observer, have led to dire results. There is, again, overlapping as regards the treatment of syphilis, a subject also dealt with by Colonel Lambkin. Mr. Power does not mention that sodium sosoiodate can be dissolved in water by the addition of a little ammonium iodide, and is employed in that form for intramuscular injection. Colonel Lambkin starts his paper with the question, "Is it necessary to treat syphilis?" Though admitting the possibility of spontaneous recovery, a categorical "Yes" must be given to such a question, and the author mentions the serious complications that may ensue when treatment has been omitted. It must also be emphatically pointed out how dangerous it is to be deluded by so-called benign syphilis. Colonel Lambkin refers to Fergusson's account of syphilis among our troops in Portugal, but this point has already been criticized in the BRITISH MEDICAL JOURNAL (Syphilis in the Uganda Protectorate, October 3rd, 1908, p. 1037), and need not be dwelt upon in this place. Colonel Lambkin is not quite correct in stating that Professor Fournier employs almost entirely the ingestion method. The outbreak of syphilis in Uganda forms the subject of another paper by the same author, which is instructive reading, but the occurrence and the various letters written on the point must be well known to our readers. Dr. W. J. Gow deals with syphilis in obstetrics in a satisfactory manner. He appears to lean towards the maternal origin of congenital or hereditary syphilis as opposed to the paternal. The evidence certainly appears to support the former very strongly indeed. The work of Matzenauer, reviewed in these columns some few years ago, should be read by those interested specially in the subject of the heredity of syphilis.

In his recent book on *Syphilis*,⁴ Mr. BEDDOES gives a very good and readable survey of the disease in its various forms and phases. The subject is dealt with in a clear and practical manner, so that the book may be recommended, but one or two points may be touched upon in passing. In the paragraphs on pathology plasma cells do not appear to be mentioned. As to differential diagnosis of the cutaneous manifestations, some diseases, such as pityriasis rosea, might, perhaps, have been a little more explicitly discussed. Although the author recognizes the utility of intramuscular injections in a general way in syphilis of the nervous system, it would have been desirable (p. 164) to insist on the value of the insoluble preparations in this respect. With regard to the marriage of syphilitics, a good deal depends on the opinion held as to so-called paternal heredity. To those who consider that paternal infection of the child may occur, the periods mentioned by the author will appear all too short. It must be borne in mind, however, that evidence distinctly points to congenital syphilis as being derived solely through a syphilitic mother, who indeed may present no sign of syphilis. Recent investigations in this direction by means of Wassermann's reaction have given positive results in instances of the latter description. Again Langbelet (cited by Matzenauer, *Die Vererbung der Syphilis*, 1903, p. 81) has recorded a case of a man with quite recent florid syphilis, who notwithstanding married. His wife did not contract syphilis, and bore a healthy child, which was subsequently accidentally infected from a syphilitic lesion of the lip of its own father. Again, a man suffering from recent syphilis may beget a healthy child, and subsequently infect his wife (von Düring, cited by Matzenauer, op. cit., p. 87; see also Discussion on Inherited Syphilis, Reports of the Society for the Study of Disease in Children, vol. viii, 1908, p. 52 et seq.). But to be on the safe side longer periods of prohibition of marriage are necessary, as the author admits. This important question, however, is one that cannot be discussed in this place.

The discovery of *Spirochaeta pallida*, since renamed *Treponema pallidum*, and the extraordinary amount of work connected with it, has quite thrown into the shade the various micro-organisms previously asserted to be the cause of syphilis. Among the latter, the bacillus of von NIESSEN,⁵ which has never been recognized by any other observer, as far as one knows, had, it was thought, quite disappeared into the bacteriological limbo, but its discoverer has never acknowledged defeat and now dons his armour once more, challenging any and every opponent of his syphilis bacillus. Unfortunately, the treponema appears to be now so strongly entrenched as to defy all competitors and to be adjudged victor. The industry and pluck of Dr. von Niessen must be acknowledged, especially in this country, where the sporting instincts are part of the national genius. One looks through the numerous plates and wonders at the enormous range of variation in the pleomorphism of the particular bacillus depicted. Polymorphism has in micro-organisms long been an admitted fact, but here the protean morphology recalls to mind the man who did not believe in ghosts because he had seen so many. From a note opposite Plate viii von Niessen appears to entertain the opinion that the spiral forms of his bacillus are identical with Schaudinn's *Spirochaeta pallida*—a point that Schaudinn did not admit when preparations were submitted to him by von Niessen. In addition to the photomicrographic reproductions of the bacillus, there are numerous illustrations of results of its inoculation in various animals, cultures, and so forth. The very complete bibliographical lists up to 1895 and from 1895 to 1908 may be found valuable. The work is excellently got up, and redounds to the credit of the publisher and the printers.

Dr. SPILLMANN's essay on syphilis of the bones⁶ is based in part upon information and specimens supplied by Fournier, whose name should be warrant for its quality. It cannot be said, however, that the book contains any serious contribution to our knowledge of the subject or that the author has devised any striking plan for guidance through the intricacies of its ramifications. It is surprising that in a book which is dated 1909, there should be no mention of the *Spirochaeta pallida*, even when an opinion is hazarded that the nocturnal incidence of the osteoscopic pains may bear some definite relation to the special qualities of the "causal agent" of syphilis. The predilection of the virus for lymphoid tissues and more particularly for the bone-marrow is noted, but there are no observations upon the recovery of the spirochaete therefrom. Upon the reaction of the central and superiosteal marrow—for the deeper layer of the periosteum is classed with the marrow proper—great stress is laid in considering the initiation of the early secondary manifestations in the bones, and in fact of all the sclerosing and protic changes.

The author does not surmount the difficulty of distinguishing histologically between the discrete and diffuse gummatous changes in the bones; he relies for explanation of the softening of the central parts, as also for the death of bone, too much upon the mechanical effects of pressure, and too little, if at all, on the changes in the vessels themselves; nor does he allow anything to the possible direct lethal action of the virus. Ricketts is mentioned, but only to dismiss it, as a factor in determining the special selection of bone by the syphilitic poison. To speak as he does of suppuration as an exceptional event is surely putting the case too strongly.

The account of syphilis of the spinal column and its simulation of Pott's disease is very good, both from the morbid anatomy and clinical points of view. In dealing with the suppurative complications of naso-cranial syphilis the occurrence of septic pneumonia and empyema might have been mentioned. It is an interesting clinical observation that the bone pains, when attacking the sternum and ribs, instead of the more commonly affected tibia, may be mistaken for an asthmatic crisis or for angina pectoris.

The chapter on diagnosis is as good as any part of the book, but, as might be expected, it would be easy to add to the list of conditions likely to be confused; there is no mention of the "guinea necrosis" described by Paget, which

⁴ *Syphilis: Its Diagnosis, Prognosis, Prevention, and Treatment*. By Thomas Fust Beddoes, M.B., B.C. Camb., F.R.C.S. Eng. London: Rebusan, 1909. (Cr. 8vo, pp. 232. 5s.)

⁵ *Der Syphilis-bacillus. Seine Geschichte, Lebensdauer, Kultur, und spezifische Pathogenität für Tiere und Menschen*. Von Dr. med. von Niessen. Leipzig: O. Neumann, 1908. (Double cr. 4to, pp. 84. Tafeln xxxv. M. 25.)

⁶ *Syphilis Osseae (Syphilis Acanth)*. Par le Dr. Louis Spillmann, Paris: G. Steinheil, 1909. (Post 8vo, pp. 134; 12 plates. Fr. 5.50.)

occurs, as Erichsen pointed out, after fevers; nor of osteitis deformans, which has been confused with chronic diffuse syphilitic osteitis. A little too much stress is laid on the presence of enlarged glands as serving to distinguish a sarcoma from a syphiloma of bone, and it is open to question whether radiography is quite the infallible touchstone it is here represented to be.

Dr. Spillmann excels in his descriptions of the appearances of gross lesions, and of dried specimens of the bones, which are here illustrated by some excellent photographs. The merit of the book lies in its usefulness as a compact essay on this particular aspect of a protean disease, and when it is mentioned that it forms one of a series dealing with many sides of the question it will be plain that the limited task essayed has been carried out with some success.

SURGICAL TEXTBOOKS.

The fifth and latest volume of the *American Practice of Surgery*,⁸ an encyclopaedic work, is the first of the series devoted to regional surgery, and fully maintains the high standard of excellence which has hitherto characterized the System. The volume is bulky, and a large portion of it is taken up by a very able contribution on the surgery of the head, by Dr. E. Archibald, of Montreal. In this and also in a supplementary article on the surgery of the cranial nerves, the author brings to bear on the discussion of many interesting questions the results of much personal experience and of a wide study of the literature. Here the reader will find full and most reliable instruction on the latest views on old problems in cranial surgery, and on modern development in diagnostic and therapeutic methods. The length of this section is fully justified, not only by the importance of the subject, but also by the rapid advance in so many of its branches. Under the heading of "Surgical Affections" are included, amongst other non-traumatic lesions, hydrocephalus, syphilis (both cranial and intracranial), chronic forms of meningitis, and even spontaneous cerebral haemorrhage. Much space, of course, is given to tumours of the encephalon, the radical removal of which, except in cases of infiltrating malignant forms, may, the author concludes from a review of recent statistics, be regarded as a legitimate operation. In his practical and well-illustrated article on the surgery of the face, Dr. de Nancrède deals very inadequately with modern methods of treatment by light, radium, and the x ray, which, in certain affections of this region, have certainly found much scope for beneficial action. The plastic operations on the face, which constitute so much of the surgical work on this region, have received full consideration in other parts of the System, and the subject of hare-lip together with a cleft-palate is discussed in a separate article by Dr. J. S. Stone. In the preparation of his article on the surgery of the eye, Dr. G. Harlan seems to have worked under rather unfavourable conditions, as the whole of this large subject is dealt with in little more than 100 pages. Though insufficient here and there in some important subjects—that of glaucoma, for instance—it is on the whole a useful, practical treatise and affords a good review of the present state of ophthalmology. The article on diseases of the ear, by Dr. R. Lewis, junr., is wanting in some points of both pathological and clinical information, but it contains a lucid and complete section on the mastoid operations indicated in acute and chronic forms of purulent otitis, which, together with contributions on sinus thrombosis and pyogenic brain disease of otitic origin, the former by J. D. Richards, the latter by Dr. Reik, add much to the practical value of the volume. The article in which Dr. F. Hartley describes the different methods of laryngectomy is a further reminder of the great attention that has in this volume been paid to operative surgery.

In preparing a fresh edition of his well-known *Manual of Operative Surgery*,⁹ Mr. Waring has carried out in a

⁸ *American Practice of Surgery*. A Complete System by Representative Surgeons of the United States and Canada. Edited by Joseph Decaut Bryant, M.D., and Albert Henry Buck, M.D. In eight volumes. Volume V. New York: William Wood and Co. (Imp. 8vo, pp. 973, illustrations 460. Subscription.)

⁹ Oxford Medical Publications. *Manual of Operative Surgery*. By H. J. Waring, M.S., M.B., B.Sc. Lond., F.R.C.S., Senior Assistant Surgeon, St. Bartholomew's Hospital; Consulting Surgeon to the Metropolitan Hospital; Examiner in Surgery, University of London. Third edition. London: Henry Frowde, and Hodder and Stoughton. 1909. (Cr. 8vo, pp. 782, 521 illustrations, 12s. 6d.)

very satisfactory manner the pleasant though onerous duties that are imposed on a successful author. This work, which is now in a third edition, has been carefully revised, and though much obsolete matter has been omitted, it has, unfortunately we think, been found necessary to enlarge the volume. A decided improvement has been effected by the addition of illustrations, which for the most part compare very favourably with many of the sketchy and diagrammatic drawings that have been carried over from previous editions. Although by its excellence and the wide favour it has gained it may fairly be regarded as beyond criticism, we still hold that this manual contains far too much superfluous matter. If it be considered that it was written as a textbook for classes in operative surgery, it is hard to conceive what service can be done, with this purpose in view, by the retention of the chapter on the methods of warding off wound-infection, and the addition of descriptions of operation which can only be performed on diseased and injured tissues.

The fourth volume of KÖNIG'S *System of Surgery*,¹⁰ written by Dr. OTTO HILDEBRAND, has now reached its third edition. It covers much the same ground as the first volume of Erichsen under the title "General Surgery," but deals less with treatment; and though, as is stated on the cover, "revised," it gives the impression that little has been added beyond short accounts of such matters as the *Spirochaeta pallida*, spinal anaesthesia, and so on. To give eight pages to hospital gangrene when less than one can be afforded for noma, and only ten for osteo-arthritis, is hardly in accordance with the relative importance of the conditions in the twentieth century. Again, to take random examples, to the account of phossy jaw no mention of its association with tuberculosis has been added; brandy is still advocated in the treatment of delirium tremens; and the section on glands recalls the writings of French army surgeons on the subject of fifty years ago rather than the cases from recent literature. At the same time there is an excellent description of tumours, and the chapters on injuries and diseases of the tissues afford all the information necessary for those reading for examinations. Our only quarrel with the book is that, instead of mere revision, some rearrangement was required to give it the full value it ought to have.

In its scope and the arrangements of its material, Professor KÜESTER'S volume on general surgery and surgical technique¹¹ differs to some extent not only from English but also from German textbooks on the principles of surgery. It is not a bulky and comprehensive treatise, but the result of a successful attempt to afford within the compass of a single handy volume a good foundation for general surgical knowledge, together with sound instruction on the practical details of modern surgical work. The needs of the advanced student who is engaged in clinical work, and also those of the busy practitioner, for instruction that is concise and yet full and useful, are met by this work, in which the disputable and dispensable are rigorously excluded in favour of subjects of decided practical importance. The first section deals, under the heading of General Surgical Technique, with the details of antiseptic and aseptic methods, with general and local anaesthesia, with the different procedures which in this country are classed as the details of minor surgery, and with the treatment of clean wounds. In the second section, which is devoted to general surgical pathology and therapeutics, there are chapters on morbid growths, on injuries of both the soft parts and bones, and a review of the important subjects of wound infections and general infective diseases. The remaining pages are taken up by a somewhat cursory survey of the surgical diseases of the different structures of the body. The book, of course, like other treatises on general surgery or surgical principles, contains few allusions to the surgical diseases of the

¹⁰ *Allgemeine Chirurgie*. Von Dr. Otto Hildebrand, Professor of Surgery in Berlin. Third edition. (König's Lehrbuch der Chirurgie, vol. IV.) Berlin: A. Hirschwald. 1909. (Sup. roy. 8vo, pp. 1008, illustrations 438. M. 20.)

¹¹ *Grundlege der Allgemeinen Chirurgie und chirurgischen Technik*. For the Use of Practitioners and Students. By Professor Dr. Freiherr v. Küster. Berlin. Berlin and Vienna: Urban and Schwarzenberg. 1903. (Sup. roy. 8vo, pp. 420, 291 illustrations, M. 10.)

different organs or regions. In his clear and thorough teaching of the latest developments in surgical technique and pathology, Professor Kuester is assisted by a profusion of good original illustrations.

GUNSHOT WOUNDS.

It may be reckoned to the credit side of the account that Major C. G. SPENCER has drawn largely on the writings of Mr. Makins, whose account of surgical experiences in South Africa has been used by every subsequent writer, for the purposes of his excellent little book on *Gunshot Wounds*.¹² The manual is intended to meet the need for a short introduction to the subject, and will satisfy the requirements of the young army surgeon. The peculiar conditions of naval warfare and the distinctive characters of the injuries, about which we know something since the Russo-Japanese sea fights, will necessitate a treatise of wider range for the naval surgeon; but the material in this book will be valuable to him so far as it goes. In a preliminary chapter on the mechanics of projectiles Major Spencer gives one of the clearest and simplest expositions of this by no means easy subject we have read. There follows an account of the general characters of gunshot wounds which is up to date and has the qualities naturally expected from wide experience. In discussing the "first field dressing," perhaps it would have been well to express boldly the feeling of incomplete satisfaction with the present pattern to be read between the lines. The American plan of having a light metal case sealed after sterilization, and the German and Japanese devices for securing aseptic handling, are improvements valuable enough to call for adoption. The succeeding chapters deal with regional and tissue injuries; that on wounds of vessels is notable in that the fogs of the old and occasionally incorrect nomenclature are not allowed to obscure the clear picture of immediate and remote consequences of injury. The author is no doubt in the right in not saying anything about recent methods of vascular suture, although in the future they may modify practice considerably. There is nothing very new to be said about abdominal injuries, but the routine adoption of masterly inactivity with discriminating resort to operative interference is well argued. It will not be long before the chapter on the surgery of the chest at base hospitals will have to include a description of positive and negative pressure chambers.

PUBLIC HEALTH.

CANDIDATES for the Public Health Diplomas are already well supplied with textbooks, most of which are revised at more or less frequent intervals, so that it requires not a little courage on the part of an author to put forward yet another. The reason given by Dr. GILBERT E. BROOKE for adding to the list is a desire to compress into one volume enough information to enable a candidate to obtain a sufficient knowledge of all the subjects required for the public health examinations. Although we cannot agree with Dr. Brooke as to the propriety of placing in the hands of a student a single volume purporting to contain all that is required for a particular examination, we consider that his *Essentials of Sanitary Science*¹³ may still serve a useful purpose. It is not by any means a cram book, though it may very properly be the only book, or almost the only one, to be studied during the month immediately preceding an examination. One of the fullest and most complete chapters is that which deals with geology, and upon this subject the public health student will find sufficient information for examination purposes. For the most part the statements made by the author are reliable and in accordance with present-day ideas. The chapter dealing with bacteriology might be expanded with advantage. There is no mention of the methods which should be adopted for

the bacteriological examination of air, water, or foods, while there appears to be some confusion in the author's mind as to the purely artificial distinction of the words "bacteria" and "bacilli." On page 185 he seems to use the term "bacteria" for non-sporing and "bacilli" for sporing organisms, but he does not consistently maintain this distinction, for on page 198 he speaks of the typhoid *bacillus* and on page 201 he refers to the Klebs-Loeffler *bacillus*. In future editions of this work the author should make it quite clear in his account of the technique of Widal's reaction that it is not a drop of blood taken from a suspected case of typhoid fever which is examined, but of the serum of the blood. He will no doubt also on revision add to the list of theories of acquired immunity from disease, and will not omit to mention Ehrlich's side-chain theory.

In a work written by an engineer upon the cause and prevention of typhoid fever we turn instinctively to that portion which deals with water supplies. Mr. WHIPPLE, in *Typhoid Fever: Its Causation, Transmission, and Prevention*,¹⁴ has shown much praiseworthy industry in gathering together records of the effects of contaminated water supplies upon the incidence of typhoid fever in a large number of towns in America, and he has come to the conclusion that generally speaking a very low typhoid death-rate indicates a pure, and a very high rate a contaminated, water supply. By the aid of diagrams he discusses the influence of public water supplies on the typhoid fever death-rates of cities, and claims to prove that when a city changes its water supply from a polluted river to that of driven wells or constructs filters to purify a contaminated water there then follows a lessened incidence of typhoid fever. Although we are not sufficiently sanguine to expect to extinguish typhoid fever by the abolition, if it were possible, of all bad water supplies, we are in entire agreement with Mr. Whipple in his crusade in favour of a pure water supply. His researches extend over a long period of time and over a large area of country, and he has put together his results and his conclusions in a very able and convincing manner.

NOTES ON BOOKS.

A WELL-KEPT lawn is a beautiful as well as a useful part of a garden, and a photograph of such a one forms the frontispiece to an inexpensive book on *Lawns and Greens: their Formation and Management*, by Mr. T. W. SANDERS,¹⁵ the editor of two gardening papers, and the author of several more elaborate works. The scope of his new book is indicated in the title, and it will be sufficient to add that the author gives special chapters to cricket grounds and golf greens. The latter contains some general observations about laying out a green which are, perhaps, rather too dogmatic, but the sections on the formation of teeing grounds and putting greens will be useful in this day of inland links. The last parts of the book deal with appliances and with miscellaneous data about seeds and manures.

In issuing the first two volumes of their *Scientific Primers—Biology* (Gibson) and *Chemistry* (Tilden),¹⁶ Messrs. Dent have given practical recognition to the acknowledged fact of the growing interest taken by the general public in scientific work. Different attitudes have been adopted by Professor Gibson and Professor Tilden in the two volumes. Professor Gibson has aimed rather at the general public, and has dealt especially with such features of biology as adaptation, sensitivity, and the larger ideas of the subject. He has a remarkable and original chapter on the skeleton from the engineer's standpoint. Professor Tilden has preferred to deal with chemistry as required by

¹² *Typhoid Fever: Its Causation, Transmission, and Prevention*. By G. C. Whipple, Consulting Engineer; with an introductory essay by William T. Sedgwick, Professor of Biology, Massachusetts Institute of Technology. New York: J. Wiley and sons; and London: Chapman and Hall, 1908. (Post 8vo, pp. 443, 50 figs. 12s. 6d.)

¹³ *Lawns and Greens: their Formation and Management*. By T. W. Sanders, F.L.S. London: W. H. and L. Collingridge. (Cr. 8vo, pp. 138, 1s.)

¹⁴ *Dent's Scientific Primers*. Edited by J. Reynolds Green, Sc.D., F.R.S. *Biology*, by R. J. Harvey Gibson, M.A., Professor of Botany in the University of Liverpool. *Chemistry*, by W. A. Tilden, D.Sc., F.R.S., Fellow of the University of London, Professor of Chemistry in the Imperial College of Science and Technology. *Botany*, by Dr. Reynolds Green, F.R.S., Editor of the Series. London: J. M. Dent and Co. (Fesp. 8vo, pp. 128 and 113 respectively. 1s. each.)

¹⁵ Oxford Medical Publications. *Gunshot Wounds*. By C. G. Spencer, M.B., F.R.C.S., Professor of Military Surgery, Royal Army Medical College, London; Henry Frowde, and Hodder and Stoughton, 1908. (Cr. 8vo, pp. 299, 5s.)

¹⁶ *Essentials of Sanitary Science*. By Gilbert E. Brooke, M.A., D.P.H., L.R.C.P. Lecturer in Hygiene and Examiner in Chemistry and Physics to the Medical Schools of the Straits Settlements. (Kimpton's Essential Series.) London: H. Kimpton. (Cr. 8vo, pp. 426; 62 illustrations. 6s.)

the elementary student in the laboratory. He starts with a gross example of the split infinitive in his first sentence, a defect that Messrs. Dent's reader might surely have expunged. Otherwise both volumes are admirably written and admirably produced. The third volume of the series is on *Botany*, and it is written by Dr. REYNOLDS GREEN, F.R.S., the editor of the series. He has dealt with the subject from the biological side, and has presented the study of a plant as the study of a living organism; in this way he has made his own book live, in contrast to the dry-as-dust catalogue of names by which a former generation of students was repelled. The remaining volumes of the series are to deal with *Astronomy*, *Geology*, *Physiology*, and *Zoology*.

The *Formulaire Consultations Médicales et Chirurgicales*, by Professors G. LEMOINE and E. GERARD¹ of Lille, the first edition of which was favourably noticed in the JOURNAL (1905, vol. ii, p. 388), has reached a fourth edition. In its new edition the book has been adapted to the new French *Code* issued last year, and in its preparation the authors have had the co-operation of M. Vanvert, Surgeon to the Lille hospitals. The changes rendered necessary are chiefly to be found in the first part, which deals with the various drugs in alphabetical order; the second part of the book is a therapeutic index with notes on treatment, which preserve the brevity commended in the first edition.

Formulaire Consultations Médicales et Chirurgicales. Par G. Lemoine et E. Gérard. Avec la collaboration de J. Vanvert. 4ème édition. Paris: Vigot Frères. 1909. (Fcap. 8vo, pp. 920. Fr. 7.)

MEDICAL AND SURGICAL APPLIANCES.

Carabosse's Improved Shoulder Exerciser.

WE have received the following description of the apparatus illustrated in the accompanying photograph for stretching the ligaments of the shoulder-joints.

It consists of:

1. A wheel fixed on a suitable stand; it is 4 ft. in diameter, and can be made to revolve in a vertical plane. The movements may be produced by hand, pedal, or otherwise. To one spoke a sliding clutch is attached, with which is connected a stirrup-shaped handle.

2. A chair, consisting of a seat capable of being moved up and down by a vertical screw support placed centrally. The back of the chair consists of a T-shaped structure, the vertical limb of which fits into brackets attached to the seat, and can be raised or lowered to suit the length of the back of the person using the apparatus. A belt is fixed to the stem for encircling the waist of the sitter. To each end of the crosspiece a belt is fixed for encircling the

shoulders. The sitter, when securely strapped to the chair, has the movements of his spinal column limited to a minimum, and the shoulder-blades are practically immobile when the shoulder-straps are securely fastened. The sitter, with his mesial plane parallel to that of the wheel, and a little further than an arm's length from it, grasps the stirrup-shaped handle, which is at first attached near the centre of the wheel. On bringing the wheel into motion, by the operator's hand or the pedal, the hand of the sitter is circumducted through a small circle at first. The circle of circumduction is gradually increased by shifting the clutch towards the rim. About sixty revolutions a minute is a desirable speed. The seat rotates on a platform, so that, without unfastening the sitter, his other arm can be subjected to similar exercise.

The Bournemouth Hydropathic Company is the owner of the patent rights attaching to the apparatus, and will on application supply it at little over net cost to any purely charitable institution.

THE PATHOLOGY OF INSANITY.

To whatever criticisms the London County Council may lay itself open on other sides, there is at least one on which its policy is unassailable. There are no diseases which more directly affect the welfare of the community, and which at the same time can be more successfully dealt with by enlightened administrative methods combined with proper medical treatment, than those which come under the head of insanity. It is therefore not too much to say that there are none as to which accurate knowledge in regard to causation and possible means of prevention is more urgently required. It is to the credit of the Council that when it took over the charge of the lunatics within the area of its jurisdiction it clearly recognized this necessity, and took steps to meet it by establishing a well-equipped laboratory for the study of the pathology of insanity. But the best-laid schemes may come to naught for the want of the right man to carry them into execution. The Council was therefore happy in finding ready to its hand for the purpose Professor F. W. Mott, who by the breadth of his scientific training, by his special knowledge of neurology and by his experience as a general physician, was peculiarly well fitted for the post. How fully he has justified the hopes of those who placed him at the head of the Claybury Laboratory is shown by the large additions to knowledge—in a region not many years ago a blank space on the map of pathology—that have been the fruits of the work done there by him and under his inspiration and guidance. The *Archives of Neurology* which have appeared from time to time under his editorship are a record of well directed and persevering research which is in the highest degree creditable to himself and to his assistants and pupils, and of which the body under whose auspices it is carried out may well be proud. The publication of the *Archives* is an event to which students of neurology and of mental disease throughout the world now look forward with well-grounded confidence that it will bring them pregnant suggestions and fresh facts throwing light on the problems in which they are interested.

The fourth volume, which has just appeared,¹ does not belie the promise of its predecessors; we can give it no higher praise. It may be noted that the title has been altered to *Archives of Neurology and Psychiatry*, a change indicating an enlargement of the scope of the publication, which seems to be warranted by the increasing readiness of medical officers of asylums to contribute scientific papers bearing upon the causation, treatment, and pathology of insanity. The hope is expressed that in this way the *Archives* may henceforth be a yearly periodical instead of appearing at irregular intervals. There can be no doubt that this would greatly contribute to the advance and spread of knowledge in regard to the subject to which it is devoted, and in the interest of humanity as well as science it is desirable that the hope will be fulfilled.

In the preface to the volume under review Dr. Mott refers to the hope expressed by him in the previous volume that the London County Council would see its way to establish in London a hospital for the investigation and treatment of mental disease still in the curable stage. The munificent offer made by Dr. Henry Maudsley, to which reference has more than once been made in the JOURNAL, has brought the foundation of such a hospital within the sphere of practical politics; and how fully the zeal of humanity which prompted the offer is according to knowledge is shown by an article from the pen of that distinguished physician which forms an appropriate introduction to the present volume. With that article

¹ *Archives of Neurology and Psychiatry* (with introductory paper by Dr. Henry Maudsley). From the Pathological Laboratory of the London County Asylums, Claybury, Essex. Edited by Frederick Walker Mott, M.D., F.R.C.P., F.R.S., Director of the Laboratory and Pathologist to the London County Asylums; Physician to Charing Cross Hospital; Fullerian Professor, Royal Institution; Corresponding Member of the Société de Psychiatrie de Paris; Foreign Associate of the Société Clinique de Médecine Mentale. Vol. iv, 1909. Printed for the London County Council, and may be purchased either directly or through any bookseller from P. S. King and Son, 2 and 4, Great Smith Street, Victoria Street, Westminster, S.W., agents for the sale of the publications of the London County Council.

and the proposal which forms its subject we deal elsewhere (p. 1020). Here it need only be said that we note with pleasure the fact that the Asylums Committee of the London County Council is favourably disposed to a scheme which is an essential part of Dr. Maudsley's proposal, and which has been repeatedly urged in the JOURNAL—that is, the removal of the pathological laboratory from its present home in the wilderness to London. It is unquestionable that the usefulness of the laboratory as a place of research, and still more as a centre of teaching, is greatly lessened by its comparatively inaccessible situation. The Pathological Subcommittee of the London County Council some time ago recommended that the laboratory should be removed to London, but, doubtless owing to economic reasons, the recommendation has so far remained the expression of a "pious opinion." While fully recognizing the difficulties that lie in the way, we think that the ultimate advantages of the proposed transfer would be so great as to outweigh any consideration of immediate cost.

A matter of great importance touched on by Dr. Mott in his preface is a proposal made by him some time ago that a special diploma in mental disease should be given by universities and licensing bodies to persons who have gone through an adequate course of training. This would tend to raise the standard of professional efficiency in lunacy practice, as the diploma in public health has raised it in the province of sanitary science. The suggestion, which was at first somewhat coldly received by those to whom the profession looks for guidance, has now, we believe, found favour in their eyes, and some steps have been taken to carry it into effect. We think the idea is thoroughly sound, and that its fulfilment would tend to the advancement of knowledge and thereby to the benefit of the nation.

Passing to the other contents of the volume, we find first the full text with illustrations of the Morison Lectures on the pathology of syphilis of the nervous system in the light of modern research, delivered by Professor Mott at the Royal College of Physicians of Edinburgh in January last, and published in this JOURNAL February 20th, p. 454, and February 27th, p. 524. In those lectures he brings the evidence of the Wassermann method of diagnosis to strengthen the thesis "No syphilis, no tabes," which he has already so powerfully advocated on the basis of statistics and observations relating to the etiology of the disease. The hypothesis that it is a bacterial toxæmia caused by a diphtheroid organism finds no support in the results of an elaborate bacteriological investigation of general paralysis made by Dr. J. P. Candler, Assistant Pathologist to the London County Asylums. Full details are given of the methods of investigation employed. We need only indicate his conclusions:

1. That diphtheroid organisms, some pathogenic and others non-virulent to man and animals, are extremely common organisms in Nature.
2. That they can be found with considerable frequency and representing several different species in all parts of the human body, but especially on serous and mucous surfaces.
3. That the genito-urinary tract affords a very frequent nidus for some varieties.
4. That diphtheroid organisms may be found either in pure culture or associated with other micro-organisms in diseases which have been proved beyond doubt to be due to another specific factor.
5. His own observations led him to believe that diphtheroid organisms cannot be isolated from cases of general paralysis with any greater ease of frequency than from cases unassociated with that disease.
6. That during the progress of general paralysis the impairment of tissue resistance facilitates the occasional entry of micro-organisms into the blood stream.
7. That the organisms which gain entry are not confined to any particular species, but may include several varieties, among which, according to the observations of others, the diphtheroid class must be included.

After discussing the grounds on which Drs. Ford Robertson and McRae base their contention that an organism of the diphtheroid species, termed by them *Bacillus paralyticans*, is the specific etiological factor in the genesis of general paralysis and tabes, Dr. Candler points out that neither his own researches nor those of Professor A. Marie, who has independently investigated the subject, support this view. That general paralytics, he adds, are liable to secondary infections and complications is not disputed; moreover, he admits the possibility that diphtheroid bacilli may play some part in these secondary infections and that the use of an antiserum prepared from

such bacilli may be followed by transitory beneficial effects. His opinion, however, is that the assumption that a particular group or groups of diphtheroid organisms act as the specific factor in the production of general paralysis is unwarranted and has not yet been substantiated by any published research.

Dr. Mott contributes interesting reports of a case of gummatous meningitis in a congenital syphilitic; of a case of localized syphilitic pachymeningitis cerebri, with speech affection; of the results of the examination of the nervous system in a case of chronic lead encephalitis; and of a case of embolism of the anterior division of the left middle cerebral artery. A paper of especial value is one on tuberculosis in the London County Asylums in which he has collected an immense body of carefully-sifted facts. The conclusions are so important that we give his summary of them:

1. The evidence adduced does not support the contention that infection is one of the *strongest* causative elements in the prevalence of tuberculosis in the London County Asylums; still less does it support the view that the causes of tuberculosis *inhere* in the asylums themselves and not in the character of the patients sent to them.
2. Notification during five years from all the London County Asylums does not show any ward incidence comparable with that shown by the notification of dysentery during the same period; therefore, if tuberculosis is communicable, it cannot be regarded as an infectious disease in the same sense as dysentery, small-pox, scarlet fever, etc.
3. The average proportion of living patients reported as tuberculous is 20 per 1,000 inmates of the London County Asylums, but the incidence of reported cases shows very considerable variations, the lowest being Cane Hill, 10.6, and the highest, Claybury, 40.3. The personal equation must largely contribute to these wide differences.
4. Association with mental disease of the cases reported during life indicates that young subjects suffering from melancholia, dementia præcox, and imbecility are especially prone to the disease.
5. Post-mortem statistics confirm this correlation, but, in addition, show that a large number of general paralytics die with recent active tuberculosis which is not diagnosed during life; this is especially the case in regard to female general paralytics.
6. In 14.8 per cent. of the autopsies made at the London County Asylums during the past five years active phthisis was found. Again, a great variation in the returns from the various asylums was noticeable, for which the personal equation must be held largely responsible.
7. It cannot be shown that the variation in the incidence of tuberculosis in the various London County Asylums depends on any measure upon the class of patient received, the parish areas from which they are drawn, the construction and age of the asylum, or the dietary or treatment. Cane Hill Asylum, situated on a high chalk down, has a comparatively lower death-rate and a lower tuberculosis death-rate than any of the other London County Asylums. The relatively higher death-rate from tuberculosis at Claybury may be explained to some extent by the fact that the necropsies are made by a skilled pathologist, but it might be attributed to the clay soil and cold, damp climatic conditions, although the total death-rate is lower than at most of the other asylums.
8. A comparison of the phthisis death-rate for 1907 at the several age-periods per sane living in London and per 1,000 of the total living insane population (48,372) resident in the London County Asylums show that the mortality from phthisis among the insane is highest at a much earlier age-period than among the sane. At the age-period 45 to 55, when it reaches its maximum among the sane, it is a question whether the incidence among the insane is much greater than among the sane pauper population.
9. The comparison also shows that the death-rate from phthisis for the insane between the ages of 15 to 35 is about fifteen times that for the sane for the same age-period. All things, however, must be made for the fact that the majority of the inmates of the asylums belong to the poorest classes.
10. The Jewish population at Colney Hatch (mainly aliens) show a higher death-rate (25.7 per cent. of total deaths) from tuberculosis than the Christians.

The following is the explanation of this fact given by Dr. Mott (p. 96): "It is generally acknowledged that syphilis is the cause of this disease, and the history of sterility, miscarriages, and stillbirths which is so frequently found in female general paralytics, together with other reasons, supports the contention that the reason that the female paralytics show a much higher incidence of active pulmonary tuberculosis than the males does not rest upon the fact that they are much less able to acquire the seeds of infection in the asylum, but that the social conditions under which a good number of them lived prior to admission, of exposure to cold and wet, of insufficient nourishment, poverty, overcrowding, and alcoholism, combined with an inborn mental and physical deficiency in a considerable percentage, produced a more suitable soil for the development of tuberculosis."

This, Dr. Mott thinks, is because the Jewish patients are largely composed of aliens who have not been long in this country; they come from Russia, for the most part, where they and their progenitors have lived in great pauperism and degradation, and, therefore, unlike the prosperous Jews, whose progenitors settled in this country several generations back, have already the seeds and soil of consumption in their bodies when they arrive in this country.

11. Evidence is not forthcoming to prove that the staff in the London County Asylums contract tuberculosis from the patients.

12. During the past ten years 1,982 necropsies were made at Claybury Asylum by skilled pathologists, and active phthisis was found in 416 cases (20.9 per cent.). Tuberculous ulceration of the intestines was found in 73 males (36.3 per cent.) and 115 females (53.4 per cent.) of the cases dying with active tuberculosis. Twenty-five per cent. of the deaths with active phthisis occurred within one year of admission, and practically 70 per cent. within five years of admission.

13. The *post-mortem* statistics for the past six years show that 51.6 per cent. of all the patients dying exhibited either obsolescent or active tuberculosis or both. It was inferred from the *post-mortem* examination that not more than 10 per cent. of the cases with active phthisis at autopsy could have acquired the disease in the asylum.

14. Infection with the disease depends upon dosage and resistance.

15. The prophylactic measures for the prevention of tuberculosis are good in the London County Asylums as regards milk, food, personal cleanliness, ventilation, clothing, warmth, and exercise in the open air, and the liability to infection from preventable causes is less than in the houses from which the majority of the insane are taken. The only further prophylactic measures consistent with proper and due economy appear to be (1) the earlier and more frequent diagnosis of active phthisis with a view to isolation and treatment; (2) the adoption of the verandah system of open-air treatment at all the asylums; and (3) the encouragement of patients suffering with phthisis to expectorate into proper receptacles, and thus possibly diminish the amount of intestinal tuberculous ulceration caused by autoinfection.

Among the papers published in the *Archives* are two by distinguished foreign investigators: one by Dr. Ariens Kappers, Director of the Neurological Institute, Amsterdam; the other by Dr. Giacomo Pighini, of Reggio Emilia. In neither case was the work done at Claybury, but the papers are included because they were offered as being connected with work that had appeared in previous issues. Dr. Kappers's researches on the evolution of the smell area, embodied in a paper entitled *The Phylogenesis of the Palaeo-Cortex and Archi-Cortex compared with the Evolution of the Visual Neo-Cortex*, correspond with those of Dr. Mott on the evolution of the visual area in mammals, published in the third volume of the *Archives*. The following is a summary of his conclusions:

The granular layer in the cortex is primary in character, and has originally receptive functions.

The infragranular layer, as already pointed out by Watson, has projection and intraregional associative functions. It increases phylogenetically after the formation of the granular layer and before the formation of the supragranular pyramids (Mott).

The supragranular pyramids—already proved by Dr. Mott to be the latest to appear—have chiefly associative functions of a higher order, and therefore are just as much dependent on the surrounding regions as on the region where they are found.

The first tactile neo-cortical centre (occurring in reptiles) belongs to the trigeminal sensibility. This is explained by the associative functions between olfactorium and oral sensibility.

The neo-cortex originates from the palaeo-cortex, and not from the archi-cortex. This explains why the corpus callosum (commisure of the neo-cortex) in the lower mammals originally runs ventrally together with the anterior commissure (commisure of the palaeo-cortex), and not dorsally with the psalterium (commisure of the archi-cortex).

Dr. Waldemar Koch and Mr. Sydney Mann contribute a chemical study of the brain in healthy and diseased conditions, with special reference to dementia praecox. According to the authors, analysis of the brain at different ages shows that with its growth there is a decrease in the amount of moisture, proteins, extractives, and ash, while the cerebrins, lipoids, and cholesterol increase. Comparison of brains from cases in which the causes of death were of an entirely different character showed no variations of importance. Analysis of the brain in nine cases of dementia praecox showed a diminution of the neutral sulphur. This variation appears to be independent of the cause of death, and so far has not been found in other forms of insanity. The authors therefore think it not unreasonable to suppose that the subjects of this disease may possess a general bodily inherent deficiency for oxidation processes. Five brains from cases of general paralysis were examined as controls; they did not show any marked changes in the neutral sulphur content of the brain. Compared with the normal, the results show that the destructive changes in this disease affect the brain generally, not one constituent in particular. Some support to the view that in dementia praecox there

is a general inherent bodily deficiency for oxidation processes is afforded by Dr. Pighini's observations on the increase of neutral sulphur in the urine in this disease. That investigator selected four typical cases of dementia praecox in the acute, and eight in the more advanced stage, and studied the metabolism of the various food elements by means of numerous analyses of the food administered and the excretions. He found that in the acute phase there is a negative balance of nitrogen (urea, uric acid, xanthin bases) and of phosphorus and sulphur, indicating a marked dissolution of the phosphorized and sulphurized proteins of the organism. In the advanced phase there is a proportionate retention of nitrogen and phosphorus, a loss of sulphur proportionate to these elements, and an independent loss of calcium. In both phases there is an altered water metabolism, and a relaxed excretion of chlorine.

Dementia praecox also forms the subject of a paper by Mr. G. H. Harper Smith and Mr. Rae Gibson, who give the results of a bacteriological examination of the cerebro-spinal fluid in the disease. They were led to the conclusion that the reported discovery of any organism in the cerebro-spinal fluid in dementia praecox should be regarded with great caution, and, in the light of the difficulties they have encountered, they suggest that any such organisms may be the result of external contamination.

We have no space to do more than mention the other papers contained in the volume. Dr. Candler reports a case of haemorrhage into the suprapneal capsule. The importance of this occurrence, he says, lies in the fact that such a lesion may occur giving rise to obscure abdominal or nervous manifestations difficult of diagnosis, and may even be a cause of death without any appreciable symptoms whatever. Dr. Helen G. Stewart gives notes and observations on forty cases of new growths, including eighteen intracranial tumours. She also contributes a description of the brain of an epileptic imbecile showing extensive heteropia of the grey matter, and a preliminary note on brain-weights and measurements in the insane. Dr. H. Devine reports and comments on an interesting case with impulsive obsessions of suicide and automutilation. Dr. Geoffrey Clarke gives a short account of the incidence at Long Grove Asylum from its opening on June 18th, 1907, to October 31st, 1908. The volume ends with the statistics relating to the percentage incidence of intracerebral and subdural haemorrhage and deposit in the insane by Dr. Mott.

Much of the work recorded in this volume of the *Archives of Neurology and Psychiatry* is necessarily of a highly technical character. But even those who have no time to study these abstruse investigations should be grateful to the patient workers who are labouring in dark mines which may at any time yield priceless gems of knowledge. It is only by such work that the hidden treasures of new truth can be gained.

The volume is abundantly and beautifully illustrated, and all concerned in its production are to be heartily congratulated on the result of their labours. To the London County Council special honour is due for the liberality with which it promotes the cultivation of a field of scientific knowledge which, but for such encouragement, could scarcely be reclaimed and put to profitable use.

THE International Congress of Psychology will hold its sixth meeting in Geneva this year from August 3rd to the 7th, under the Presidency of Professor Th. Flournoy. The programme includes discussion of general and special topics, questions of standardization, demonstration of apparatus, and individual papers. The general topics to be discussed are feelings—"sentiments" (by Külpe and Sollier), subconscientness (Dessoir, Janet, Prince), measure of attention (Patrizi, Ziehen), religious psychology (Höfding, Leuba). The special topics are the psychopedagogical classification of backward pupils (Decroly, Ferrari, Heller, Witmer), pedagogical psychology (Ioteyko), orientation at a distance (Thauziès), perception of position and movement of the body and limbs (Bourdon). Under standardization will be included terminology, standard colours, enumeration of errors in testimony experiments, notation of age of children, mathematical determination of numerical results of experiments. Communications relative to the Congress should be addressed to the General Secretary, Professor Ed. Claparède, 11, Avenue de Champel, Geneva.

LITERARY NOTES.

THE publishing business established at Edinburgh over forty years ago by Messrs. Edward and Stuart Livingstone has been bequeathed to Dr. Alexander Walker. Dr. Walker, who has retired from practice, is carrying it on with his son under the management of Mr. H. M. McKechnie, who was for some years assistant with Mr. Young J. Pentland. It is the intention of the firm to maintain the reputation it has gained for the production of high-class medical literature.

In a supplement to its March issue, the *Indian Medical Gazette* gives a report of the proceedings of the Medical Congress held at Bombay last February. It is well arranged, and summarizes without superfluous detail a large amount of good work.

The *Eugenics Review*, of which we have received the first number, is to be the organ of the Eugenics Education Society. In a "foreword" Mr. Francis Galton emphatically disclaims "rivalry in any form with the more technical publications issued from time to time from the Eugenics Laboratory of the University of London now located at University College." On the contrary, the purpose of the *Eugenics Review* is to supplement them. Elsewhere we are told that the new review is not like unto other reviews. "It has a definite plan and purpose, the noblest that can be imagined—the betterment of the Human Race." Among the contributors to the number before us are Mr. M. Crackanthorpe, K.C., the Rev. Dr. W. R. Inge, and Sir Edward Brabrook, C.B.

Another new periodical on our table is the *British Health Review*. The editor, Mrs. L. Hodgkinson, in an opening article, discusses the medical profession and the public. The writer foresees a great change in their relation to each other. It is comforting to be assured that the doctor's position must enormously gain in importance, "for, instead of relegating the medical profession to the ambulance service of humanity, we shall regard its members as the guardians of health, and generals in the battle with all the preventable diseases that decimate our ranks to-day. They shall teach us to out-general these evils, to use the weapons of precision with which they will arm us, to rally to our aid every friendly force, every natural advantage, until in this warfare also we may beat our swords into ploughshares, and 'the trumpet shall sound Release.'" One object of the *British Health Review* is, we gather, to dissipate the ignorance of the public in regard to the machinery of life and the processes by which health is maintained. Another is to create a better understanding between the medical profession and the public, "making it clear to the former that none of our old gratitude for their sympathy and humanity has deserted us in the new call we make upon their more intellectual qualities, and to the latter that the greater half of the responsibility for disease and degradation rests upon their own shoulders, and can in no wise be shifted or ignored." The editor has for this reason invited many well-known doctors and surgeons to put before the readers of the *British Health Review*, in a language understood of the people, what it is essential for them to know. The intention is excellent, but the trail of the diet faddist is over the periodical; and though it would, perhaps, be too much to say, from an inspection of one number, that it is written by cranks for cranks, we cannot honestly say we think it likely to fulfil its useful but somewhat difficult mission.

In a paper reprinted from the *New York Medical Record*, Dr. Herbert S. Birkett, of Montreal, gives a brief account of the history of medicine in Quebec from 1535 to 1838. Canada celebrated the three hundredth anniversary of the foundation of Quebec on July 3rd, 1908, but the history of medicine in that province began seventy-three years before, when Jacques Cartier built a rude fort on the banks of the St. Charles facing the Indian village of Stadaconé. Leaving his men to construct an abode against the coming winter, he sailed up the river St. Lawrence as far as the village of Hochelaga, the site of which includes a part of the grounds of McGill University. On his return he found his crew suffering from scurvy. Among them was a man who evidently had some knowledge of medicine, for he made a

post-mortem examination on the body of a young man named Rougemont, in order to ascertain the cause of death, and, if possible, save the remnants of the ship's company. The following is the record of the first autopsy performed in Canada:

He was found to have his heart white, but rotten, and more than a quart of water about it; his liver was indifferent faïre, but his lungs blacke and mortified, his blood altogether shrunk about the heart so that when he was opened, great quantitie of rotten blood issued out from about his heart; his milt towards the backe was somewhat perished, rough as if it had been rubbed against a stone. Moreover, because one of his thighs was very blacke without, it was opened, but within, it was whole and sound: that done as well as we could, he was buried.

The captain, having witnessed an apparently marvellous recovery from scurvy in an Indian, found that the specific used was the bark and sap of a tree called in the native tongue "Améda." This tree is known to-day as "l'épinette," or the spruce. The method of preparation was as follows:

To take the bark and leaves of the said tree, and boile them together, then to drink of the sayd decoction every other day, and to put the dregs of it upon his legges that is sicke; moreover they told us that the vertue of that tree was to heale any other disease.

The sailors were much troubled with the "French Pockes," but after liberal doses of the bark they were "cleane healed." This fortunate result led to such a demand for the remedy, that men were ready to kill each other in their eagerness to test its efficiency—

so that a tree as big as any oak in France was spoiled and lipped bare, and occupied all in five or six daies, and it wrought so wel, that if all the phisicians of Montpellier and Lovaine had bene there with all the drugs of Alexandria they would not have done so much in one yere as that tree did in six daies, for it did so prevaille that as many as used of it, by the grace of God, recovered their health.

When Champlain arrived in Canada in 1608 there was in his company a surgeon named Bonnerme, who however soon died of scurvy or dysentery. Among the earliest settlers in Quebec was Adrien Duchesne, a surgeon of Dieppe, who probably arrived in 1618. When Champlain surrendered the fort to Sir David Kirke in 1629, Duchesne remained and practised his profession under the English flag. His practice extended from Quebec to the post at Three Rivers midway between Quebec and Montreal. Another contemporary of Champlain was Robert Giffard, who went to Quebec in 1628 as surgeon to the company of "The Hundred Associates." He took a considerable part in inducing families to settle in the colony, and was a member of the Council, a body empowered to enact local laws and to adjust differences between private persons. He practised in Quebec and the surrounding country, and was visiting physician to the Hôtel-Dieu founded in 1639. In 1658 Jean Madry, a surgeon of Quebec, while on a visit to France obtained from Barnois, first surgeon in ordinary to the King and head of the College of St. Côme, "Letters of Surgeon" for himself, "with power to establish in all parts of Canada the authority of surgery in order that the sick might receive more efficient medical care." These letters were registered in the Sovereign Council at Quebec, but they do not seem to have been much service to the profession. Madry was elected the first Mayor of Quebec, but the office was abolished after five weeks. About this time the need of a larger number of doctors was felt by the growing community and Jean Martinet undertook to teach his brother-in-law, Paul Prudhomme, by the system of apprenticeship. A physician of note of this period was Gauthier, who discovered the wintergreen plant which bears his name (*Gaultheria procumbens*). Another important doctor of the time was Michel Sarrasin, head of the medical staff of the Hôtel-Dieu. He was delegated by the French Académie des Sciences to make a special study of animals and plants in Canada. He made anatomical researches on the beaver, the muskrat, the seal, and the groundhog, and discovered the pitcher plant known to-day as the *Sarracenia purpurea*. Even in the eighteenth and early part of the nineteenth century there was no means of learning the art of healing in the Province of Quebec except by apprenticeship. The first student who went abroad to study medicine was François Blanchet, born in 1776. He was an active politician and a journalist as well as a physician. As was natural in a country

where there was no provision for medical education and where the demand for medical assistance far exceeded the supply quackery was rampant. To remedy this state of affairs the Intendant Bigot in 1750 introduced an ordinance which may be considered the code of the medical profession in Canada. This provided that no one should practise medicine without passing an examination. Those wishing to practise in a city were to be examined before the Physician of the King in the presence of the Lieutenant-Governor of the Jurisdiction. Those wishing to practise in the outlying districts were to pass an examination before the Physician of the King and a subdelegate. This ruling continued until 1788, when the British Parliament passed an Act which provided that no one should practise physic and surgery within the Province of Quebec, or midwifery in the towns of Quebec and Montreal, without a licence. A licence was to be obtained by passing an examination conducted by capable persons appointed by the Governor or Commander-in-Chief of the Province. This ordinance had a radical fault. It placed the study and the practice of medicine absolutely in the hands of the executive power, and this opened the door to partiality, injustice, and administrative tyranny. The Ordinance of 1788 was repealed in 1831, and by an Act passed in 1847 the medical profession in Lower Canada was incorporated under the name of "The College of Physicians and Surgeons of Lower Canada," and was empowered under certain restrictions to frame its own statutes for the regulation of the study of medicine in all its departments, and by-laws for its own government. In 1849 an amendment to this Act was passed, which authorized the Provincial Medical Board to issue licences.

THE ANAESTHETICS BILL.

MR. NORMAN G. BENNETT, Honorary Secretary of the British Dental Association, has issued a letter calling the attention of the members of that body to the fact that a measure entitled the "Anaesthetics Bill, 1909," was presented to the House of Commons on March 25th. The object of the bill, he says, presumably is to protect the public as far as possible against deaths arising from the administration of anaesthetics by unqualified persons. The bill proposes to do this by the following provisions:

1. Prohibiting the administration of any general anaesthetic by other than a legally qualified medical practitioner. Dentists registered "before the commencement of this Act" are exempt so far as the administration of anaesthetics "during a dental operation or procedure" is concerned.
2. On and after January 1st, 1911, no person may be registered under the Medical Acts "unless he shall have produced evidence that he has received theoretical and practical instruction in the administration of anaesthetics."

Mr. Bennett states that the executive of the British Dental Association is of opinion that it is unjust and unwise to deprive dentists who may be registered after "the commencement of the Act" of the right to administer anaesthetics for dental operations; and that the omission of local anaesthetics from the prohibition enjoined is calculated to defeat the object of the bill. This opinion is based on the following considerations:

1. There is no evidence to show that the employment of anaesthetics by dentists for dental operations has been a danger to the public.
2. Registration in the *Dentists Register* gives the right to practise dentistry or dental surgery in all its branches. The administration of anaesthetics, as an integral part of the practice of dentistry, and of the privileges acquired by registration, has never before been challenged.
3. The curriculum of the dental student is of such a nature that the average dentist has more experience and skill in the use of anaesthetics for dental operations and the avoidance of dangers than the average medical practitioner.
4. In country districts the deprivation of the right of dentists to administer anaesthetics would be a great hindrance to practice, and react with great hardship on the poorer class of patients who cannot afford to travel to the larger towns, where the dentist and the doctor may be found in close proximity.
5. Whilst the bill would entail no hardship upon the very rich or the very poor, who, in the one case can well afford to pay fees to both operator and anaesthetist, and in the other can continue to attend at the hospital, it would press very hardly upon the lower middle class, who would be unable to pay the double fee.
6. The proposed measure, prohibiting the use of general anaesthetics by unregistered persons for dental operations, would

of itself defeat its own object, because it would inevitably lead to the exclusive use of local anaesthetics. Most preparations for the production of local anaesthesia contain cocaine, and the use of this drug is attended by considerable risk, because of its variable effect on different persons. If the object of the bill is to be attained, it is essential that local anaesthetics should be included with general anaesthetics in the prohibition enjoined by the bill.

Mr. Bennett invites members of the Dental Association to place these considerations, by way of a private letter, before their Parliamentary representative, and to ask his support for the amendment of the bill in the two essential particulars, namely:

- (a) That all dentists, registered before and after the commencement of the Act, should be exempt from the prohibition so far as the administration of anaesthetics for dental operations is concerned.
- (b) That local anaesthetics should be included with general anaesthetics in the prohibition.

The bill, it is said, will be brought forward for second reading towards the end of this month.

THE PLAGUE.

PREVALENCE OF THE DISEASE.

INDIA.

DURING the weeks ended January 23rd, 30th, February 6th, 13th, 20th, 27th, and March 6th, 13th, and 20th, the deaths from plague in India numbered 2,306, 2,897, 3,076, 3,162, 3,087, 3,750, 4,100, 4,593, and 4,530, giving a total of 31,481 between January 16th and March 20th, 1909. In the Bombay Presidency during the nine weeks in question, the deaths from plague numbered 6,599 (580 first week, 1,061 last week); in Bengal the numbers were 4,732 (first week 205, last week 2,277); in Madras Presidency the deaths have been insignificant in number: United Provinces, 4,921 (first week 334, last week 1,047); Punjab, 6,541 (first week 334, last week 1,047); Central Provinces, 3,151 (first week 334, last week 250); Rajputana 2,322 (first week 335, last week 334); Burma 3,544 (first week 357, last week 233). The total number of deaths from plague in India between January 1st and March 20th, 1909, amount to 35,801, giving an average of 453 per day. It will be seen that the year 1909 is showing, as did 1908, a marked retrocession in the number of deaths from plague. In districts where plague has been especially severe, as in the Punjab, the population has been so markedly reduced in numbers that wages have increased considerably, owing to the scarcity of finding labourers. One effect of this difficulty of obtaining labourers is that machinery is being introduced into the Punjab to an extent unknown hitherto.

HONG KONG.

DURING the weeks ended February 23rd, March 6th, 13th, 20th, 27th, and April 3rd and 10th the fresh cases of plague numbered 4, 3, 4, 1, 5, 6, and 1; the deaths from the disease during the weeks in question amounted to 3, 2, 1, 5, 4, 5, and 0 respectively.

JAPAN.

BETWEEN December 17th, 1908, and January 20th, 1909, the cases of plague reported were 32.

STRAITS SETTLEMENTS.

One case of plague reported, February 1st, 1909.

MAURITIUS.

One case of plague reported during the week ended February 13th, 1909.

EGYPT.

FROM January 6th to March 12th the fresh cases of plague numbered 25, and the deaths from the disease 13. The cases are reported from Deirut, Mallawi, and Bahiava.

TURKEY.

IN Bagdad, from January 4th to February 8th, 12 fresh cases of plague reported, 7 fatal.

GERMAN EAST AFRICA.

On January 8th, a fresh case of plague was reported.

THE AZORES.

IN the island of Terceira, cases of plague still occur: during the two years, January, 1907, to January, 1909, the cases of plague numbered 232, with 112 deaths from the disease.

IN the island of Fayal, between July, 1908, and January 31st, 1909, the cases of plague reported were 19, of which 6 proved fatal.

SOUTH AMERICA.

Chile.—At Talta and Mejillones plague is reported.

Peru.—Plague occurred in several towns during 1908. In Callao and Lima, during January, 1909, several fatal cases were reported.

Brazil.—On February 1st, plague was epidemic in Bahia. IN Rio de Janeiro 57 cases were reported between November 16th, 1908, and January 17th, 1909.

Ecuador.—From Milagro and Tolté, between November 17th, 1908, and January 17th, 1909, 47 cases of plague were reported.

Medical News.

THE Duke of Northumberland, President of the Royal Sanitary Institute, will preside at the annual dinner to be held on May 11th at the Langham Hotel.

THE Road Club (Carlton House, Regent Street, S.W.) has recently arranged to provide free accommodation for the motors of country members visiting London at the club's garage in Jernyn Street.

THE Royal Mail Steam Packet Company has published an illustrated booklet giving particulars of the Whitsun pleasure cruises that can be made by their steamers to Spain, Portugal, Gibraltar, Morocco, Canary Islands, and Madeira.

ON April 14th Dr. Thomas Sellar, who has practised in Aberlour (Banffshire) and district for twenty-five years, was presented by patients and friends with a motor car. Nearly every family in the district was represented in the subscription list.

THE British Balneological and Climatological Society has chosen Torquay as the place for its provincial meeting this year, the date fixed being Saturday, May 8th. Arrangements have been made to allow of members remaining over Sunday to explore the neighbourhood.

It is announced that Dr. Tatham, who for the last sixteen years has held the office of Superintendent of Statistics of the General Register Office, will shortly retire under the age clause, and that he is to be succeeded by Dr. T. H. C. Stevenson, School Medical Officer, Somerset.

LECTURE and laboratory courses in tropical medicine, public health, and sanitation, including school and factory inspection, have been inaugurated at the New York Post-Graduate Medical School and Hospital, and will be given with the co-operation of the United States Army and United States Navy Medical Corps.

THE Spring meeting of the South-Eastern Division of the Medico-Psychological Association will be held, by the courtesy of Dr. E. S. Pasmore, at the Croydon Mental Hospital, Upper Warringham, on Tuesday, April 27th. Dr. Pasmore also invites the members to luncheon at 1.30 p.m. Dr. T. Clave Shaw will read a paper on the clinical value of consciousness in insanity.

A SERVICE for members of the University of London will again be held on presentation day in Westminster Abbey. It will take place at 6 p.m. on Wednesday, May 12th, when the sermon will be preached by the Rev. Canon Barnett. Further particulars can be obtained from the Honorary Secretaries of the Westminster Abbey Service Committee, 88, Gower Street, W.C.

A CONFERENCE of the Friendly Societies' Medical Alliance was held at Darlington on April 12th, when it was reported that the alliance comprised thirty-one associations with a membership of 283,983, an income of £49,649, and an expenditure of £49,222. A resolution was passed to the effect that the conference would not recognize any decision accepting a wage limit for medical attendance.

THE Lord Mayor of London will preside at a meeting on behalf of the National League for Physical Education and Improvement to be held at the Mansion House at 4 p.m. on Wednesday next. The Bishop of Ripon, Lord Ashbourne, and Lord Halsbury will address the meeting, calling attention to the work of the league and emphasizing the necessity for improving the physical welfare of the nation, whether for defence or commercial prosperity. Tickets of admission can be obtained from the Secretary, 11, Southampton Row, London, W.C.

A PROVINCIAL sessional meeting of the Royal Sanitary Institute will be held at the University, Birmingham, on Saturday, May 8th, when a discussion on tuberculosis and the milk supply will be opened by Mr. J. Malcolm, F.R.C.V.S., Veterinary Superintendent, Birmingham Corporation, at 11 a.m. In the afternoon a visit will be paid to the farm at Tyburn, where a herd of cattle is in the process of being freed from tuberculosis, and afterwards to the sewage purification works of the Birmingham Tame and Rye District Drainage Board.

THE Society for the Propagation of the Gospel in Foreign Parts has recently created a medical mission department, and the first public meeting in connexion with it is to be held at the Church House, Westminster, next Wednesday, at 8 p.m. The speakers include Professor Clement Cooper, of Shanghai; Dr. Hugh Weir, of Korea; Dr. Jane Walker, Dr. Champeys, and Sir Dyce Duckworth. Information respecting the new department will be gladly supplied to those interested by its Secretary, the Rev. W. P. Dott, 15, Tufton Street, S.W. For the meeting no tickets are required.

THE British Committee, of which the honorary secretaries are Mr. D'Arcy Power, 10A, Chandos Street, W., and Dr. Clive Riviere, has received a communication from the central office of the Royal Hungarian State Railway at Buda-Pesth stating that that office has been entrusted with the duty of finding accommodation for members attending the sixteenth International Congress of Medicine, to be held at Buda-Pesth from August 29th to September 4th. The accommodation is arranged in three classes, and the intending visitor must give notice and remit the price beforehand.

THE first portion of the Royal National Orthopaedic Hospital, the institution which represents the three orthopaedic hospitals previously existing, was declared open by Princess Alexander of Teck on April 20th. This is the outpatient department and nurses' home, and consists of a building of several floors. The lower part, entirely given up to the out-patient work, provides a waiting hall, six consulting rooms, an orthopaedic gymnasium, and massage and electrical annexes. The upper floors, which have been furnished by subscriptions from nurses and their friends, constitute a complete nursing home. The building has three entrances, those for nurses and for the medical staff being in Bolsover Street, and that for patients in Euston Road. Of the total anticipated expenditure some £25,000 still remains to be collected.

THE object of the Factory Girls' Country Holiday Fund is fairly well covered by the title. In its essence the fund is a kind of beneficent tourist agency for young women working in London factories; in addition to making arrangements with cottagers for the accommodation of factory girls, the fund pays a part of the expenses out of the money placed at its disposal by subscribers. This sufficed last year to enable it to send over 5,000 girls for a fortnight of fresh air and country life. The total expense was £3,925, of which £1,550 was paid by the girls themselves. The fund, which is managed on thoroughly business-like principles and well worthy of support, has for honorary secretary Miss Paget, 28, Camden Hill Square, W.

THE directors of the thermal brine springs at Oeynhausen Spa, Westphalia, issue an illustrated pamphlet giving full particulars of the chemical constituents of the springs, of the arrangements for the comfort and treatment of patients, and of the means of reaching Oeynhausen from this country, the routes being by Flushing, Hook of Holland, Ostend, or Calais. There are four springs rich in carbonic acid gas, and two simple brine springs. The bathing arrangements are good, and by mixing and heating the baths can be given at different temperatures and different strengths in salt and gas. The place is especially known as suitable for treatment of disorders of the nervous system, but its waters resemble those of Nauheim, and are used also for disorders of the heart and vascular system. There is an institute fitted with mechanical appliances suitable for use in disorders of the joints and bones. The waters have also been recommended in diseases of women, in affections of the respiratory organs, and in disorders of metabolism and digestion.

AT the Nursing and Midwifery Conference and Exhibition held last week in the Grafton Galleries, London, Dr. T. Outterson Wood, in the course of an address, said that the great want felt at the present time in the nursing world was one uniform system of training, examination, and certification, that a definite standard of proficiency might be reached which would entitle successful candidates to a qualification, not of this or that hospital—which might be a variable quantity—but of one great qualifying body. Nurses might broadly be divided into the following classes: (1) The general hospital trained, including medical and surgical; (2) the hospital nurse, who has in addition special training, such as fever, children, etc.; (3) obstetric nurses, or midwives; (4) the mental or asylum trained, including male and female. He referred to the several organizations that existed to register the above classes. There was the Royal British Nurses' Association, which was promoting legislation for the State registration of nurses. The Medico-Psychological Association of Great Britain and Ireland had already one uniform standard of training, examination, and certification. There was also the Asylum Workers' Association and Queen Victoria's Jubilee Nurses, while the midwives had their own association, known as the Midwives' Institute. Dr. Wood said that he was glad to see that in the bills before Parliament for the State registration of nurses the medical profession was well represented upon the proposed council. If State registration became an accomplished fact, the scale of fees would have to be arranged upon a reasonable basis, as otherwise many nurses would be deterred from registering, and the movement would be a failure.

British Medical Journal.

SATURDAY, APRIL 24TH, 1909.

A MENTAL HOSPITAL FOR LONDON.

IN the JOURNAL of February 22nd, 1908, there was published a letter addressed by Dr. Henry Maudsley to Mr. H. P. Harris, Chairman of the London County Council, in which he offered to contribute £30,000 towards the cost of establishing in London a properly equipped hospital for mental diseases. The outline of the scheme suggested in conference with Mr. Harris was that the hospital should be for 100 patients suffering from recent and mostly acute insanity; that some 60 or 75 of these should be of the poorer class, for whom the parishes would pay, as is the case now with those sent to county asylums; and that the remainder should be private patients who would pay a sum sufficient to prevent their being a burden on the ratepayers. An integral part of the scheme was that the hospital should be an educative as well as a curative institution, and that for this purpose, as well as for the conduct of research into the pathology of insanity, it should have attached to it a laboratory such as that at Claybury, where, notwithstanding difficulties arising from its remote situation, Dr. Mott and his assistants and pupils have done so much excellent work. Dr. Maudsley's offer was, on the recommendation of the Asylums Committee, gratefully accepted by the Council, which further voted a sum of £100 for the preparation of sketch plans of such a hospital as Dr. Maudsley had in view. These facts were announced in the report of the Asylums Committee for the year ended March 31st, 1908, where it was further stated that inquiry was being made for a suitable site. In the JOURNAL of December 19th we pointed out how fully the committee was in sympathy with the proposal to build a hospital for mental diseases, and how clearly it perceived the need of a central pathological laboratory in close touch with the hospital. So far, however, the scheme has made no visible progress towards concrete embodiment. We have reason to believe that the Council is moving in the matter, but we confess we should be glad to have fuller assurance that the hospital will not be allowed to remain, like a phantom *Dreadnought*, stranded on the rock of short-sighted economy.

In the circumstances we are fain to regard as a good augury the fact that Dr. Maudsley has contributed to the new volume of Dr. Mott's *Archives of Neurology and Psychiatry*, recently issued by the London County Council, an introductory essay in which he sets forth his views as to the aims and uses of a mental hospital. With his well-known lucidity and grace of style the distinguished writer discusses the factors concerned in the production of insanity and the different manifestations of brain disease. According to him, the varieties of insanity fall naturally into two principal classes. When the material element is damaged, either by direct injury or by toxins introduced into the body or engendered in it by some mishap in the processes of metabolism, its disordered energies are displayed in the in-

coherencies of delirium and acute delirious mania. In the other class of cases the disorder shows itself rather in a dissociation of the federal tracts or centres and in the steady organization of disorder. These "organized insanities" differ in symptoms, pathology, and mode of causation from the insanities of positive nervous deterioration. In them, says Dr. Maudsley, the question is not so much one of material injury to nerve element as of the steady development of a morbid character from the root of a bad constitutional inheritance. Nursed passion or prejudice ripens into bad habit of thinking and feeling, and bad habit grows into organized disorders. This leads him to the suggestion that part of the work of a mental hospital might be systematic instruction in mental hygiene in its widest sense; such instruction should be based on demonstration by actual examples of the natural and necessary effects of bad habits of thought and feeling.

Dr. Maudsley goes on to point out that as there are two different classes of insanity, so there are two different orders of inquiry to be pursued in the investigation of the disease. There is first a pathological inquiry into the physical and chemical causes of the mental derangement, and into the minute changes of structure associated therewith; for this purpose a well-equipped laboratory in the hospital is indispensable. In the next place, a more general inquiry should be made into the individual character, the hereditary influences which have wrought in its constitution, and the circumstances of life which have affected its development. Dr. Maudsley points out that it is not sufficient to consider the organism only as a physiological machine liable to derangement by subtle toxic matters; it is necessary to study the patient also as a social being. Broadly speaking, he says, insanity is such derangement of mind as prevents its victim from discharging his normal functions in the social body of which he is a member; therefore the nature of the social medium and his relations to it must always be well considered in a true exposition of its causation and character.

Passing to the consideration of the educative function of a mental hospital, Dr. Maudsley says that, alike in the interest of medical men who may be called upon to certify and are liable to an action at law for what they do, and of those who are liable to be certified and may afterwards be socially prejudiced by the fact of certification, it is most desirable that medical students should have a thorough knowledge of what constitutes a good and sufficient certificate of insanity, what certification involves, and in what cases it is justified. At present, we are told, it would hardly be an exaggeration to say that more than half the certificates signed are sent back by the superintendents of asylums for correction or amendment. Then a well-staffed mental hospital would supply clinical instruction to students such as would adequately fit them for their work when they go into practice. It would also supply a succession of trained medical men, interested in the special study and imbued with a scientific spirit, available to take office in the county asylums. A small hospital would also serve as an excellent training ground for nurses and attendants, who could afterwards go into the service of the large asylums efficiently prepared for the responsible duties they would have to discharge.

Dr. Maudsley strongly expresses the belief that a complete clinical and pathological study of insanity cannot be made without a thorough knowledge of all

the diseases treated in general hospitals and the morbid effects discovered in their pathological laboratories. A mental hospital should, therefore, be in close and constant touch with the medical work and thought of the general hospitals. On the other hand, these would in this way have the opportunity of enlarging the range of their work so as to include a study of the special mental features of the different bodily diseases. May not, Dr. Maudsley asks, every bodily disease perchance its special mental complexion? Every sound thinker must agree with him that the distribution of diseases, mental and bodily, into separate compartments, and the corresponding isolation of minds limited to the study of them, contradict the very principle of the unity of body and mind and form a most serious hindrance to the progress of medical science.

Passing to the question of treatment, Dr. Maudsley says that a small hospital filled with a constant succession of patients would evidently afford opportunities of such particular attention to individual cases as cannot well be given in a large asylum crowded with persons in all stages of mental disease for mere detention. Not only could more close and exact observations be made, but the attendance of physicians and students stimulating one another by constant intercourse, and occupied at the same time with the study of diseases in the general hospitals, would sharpen observation, suggest inquiries, keep fresh the interest, and prevent routine of thought, feeling, and treatment. The insane patient also could hardly fail to benefit by the surrounding atmosphere of sanity. On the purely practical side, he adds, it is hardly possible to overrate the good which may be done by individual treatment applied particularly to the susceptibilities of the individual character. He goes on to point out that another probable advantage of the close observation day by day of the individual patient would be a perception by physicians and nurses of the favourable psychological moment when at the dawn of convalescence the opportune removal from the asylum to a convalescent institution or to private care might save the tottering reason of the patient who, then awakening to the painful consciousness of his sad surroundings, and realizing the seeming hopelessness of the situation, might otherwise sink into despair, abandon hope, and drift into dementia.

That there are crowds of incurable cases of insanity congregated in large asylums is, according to Dr. Maudsley, undoubtedly due in some measure to the common neglect of early treatment when the malady is most curable. The longer the disease has lasted the smaller are the chances of recovery, and the time soon comes in some cases when, if neglected, there is no remedy. Here, as everywhere, the right treatment is to stop the beginnings of mischief. He thinks it may reasonably be expected, therefore, that besides the prevention of incipient insanity by wise counsel and treatment in its out-patient department, the early treatment of acute insanity in a special hospital will obviate the present necessity and perhaps lasting expense of placing some patients in a lunatic asylum—the very name of which is perhaps a terror, the remembrance a sort of nightmare, and the social consequences a lifelong prejudice.

We have given, for the most part in the author's own words, the gist of Dr. Maudsley's illuminating essay. Coming from a man of such knowledge, judgement, and experience, it will, we hope, stimulate the London County Council to vigorous action in carrying into effect, with the least possible delay,

a scheme as to the usefulness of which in the public interest there can be no possible doubt. Dr. Maudsley has not only shown those responsible for the care of lunatics in the County of London what should be done, but has offered to bear a large part of the cost. It now only remains for the Council to see that his benevolent intention is not defeated by the dread of interested or ill-informed criticism.

THE PREVENTION OF PUERPERAL FEVER.

THE last word as to the prevention of infection in the puerperium has still to be said, and, judging from the differences of opinion expressed by the professors of the obstetric art, that word will not be spoken for some time to come. In the meantime we have to face facts, and the two facts which affect the problem are, first, that puerperal fever is a preventable disease; and, secondly, that deaths from this disease still continue to take place. The introduction of antiseptics and later of asepsis has materially diminished the incidence of infection, but not to the extent which has been seen in surgery.

It is difficult to fix the blame in the proper quarter, for, on the one hand, we are assured that midwives are largely responsible for the infections, and that the practitioner is not free from fault, while, on the other, there are those who hold that the patient herself forms the source of danger through the bacteria which infest her external, and even her internal, parts, though there are others who regard the vaginal inhabitants as the chief safeguard against infection with pathogenic bacteria. We may therefore feel grateful to Professor Hofmeier for giving us the advantage of his experience of 10,000 births in the Würzburg obstetric clinic.¹ It must be recognized that certain difficulties stand in the way of obtaining the very best results in a German university clinic, since in the first place the students and pupil midwives examine the patient more frequently than can be quite good for her; and, secondly, the difficult cases which are referred to the clinic for treatment are frequently examined with but prefatory care outside by the practising midwife or medical man before being transferred. These factors apply equally to all clinics, and it is therefore interesting to compare Hofmeier's report from the Würzburg school with Professor Krönig's clinic at Freiburg, in Baden, where methods diametrically opposed to what is taught elsewhere are adopted.

Hofmeier's patients included abnormal cases in the high proportion of 15.36 per cent. The complications met with included all the conditions which give the obstetrician the most trouble and anxiety. The morbidity, calculated on the basis that every case which shows one reading of the thermometer of over 100.4° F. must be regarded as pathological, proved to be 11.48 per cent. The percentage of patients who had one or more rises of temperature as a result of the puerperal process was 6.35, but only 2.18 per cent. became seriously ill. Among the 10,000 women 56 died, 9 of puerperal infections. Of these 9, only 4 can have been infected in the hospital; but the brief records of these 4 cases show that only in 1 could it be definitely shown that the infection arose in the clinic, while the probability of an outside infection in the remainder was great, so that under the most unfavourable interpretation, 0.04 per cent. died of infection; among the last 7,000 patients not a single life was lost from this cause. The results,

¹ *Munch. med. Woch.*, September 15th, 1908.

therefore, may justly claim to be placed among the best obtainable. Kronig teaches that the genitals, both external and internal, should neither be washed nor disinfected, and that no vaginal examinations should be carried out, but that all should be made *per rectum*. Yet Hofmeier not only allows vaginal examinations, but trusts to a conscientious disinfection of the hands of the students and midwives and of the external parts of the patients.

Professor Max Henkel, of Griefswald, believes¹ implicitly in Ahlfeld's hot-water alcohol disinfection of the hands, but states that those who do not think this method trustworthy have in sterile rubber gloves a trustworthy means of preventing the introduction of bacteria from without. He states that among the bacteria of the vagina streptococci are often to be found, and is of opinion that the chief danger for the patient lies in the small scratches and tears, through which the virulent bacteria may enter. For this reason he objects to all unnecessary examinations, especially before the membranes have ruptured. He holds that in the majority of cases the presentation can be made out by external examination. Hofmeier, in replying to those bacteriologists who state that no hands can be rendered sterile, takes the different ground that the search for the last bacillus is a matter of indifference. Hands which have been well washed with soap and water and subsequently disinfected with a 1 in 1,000 solution of corrosive sublimate are sufficiently sterile for practical purposes. If these precautions are carried out, he contends that the number of digital examinations made is immaterial.

On the other hand, it cannot be admitted that an incidence of over 2 per cent. of serious febrile infections in childbirth is ideal, if these infections are to be regarded as really preventable. It is only fair, however, to the clinics and to the methods adopted in them to inquire what proportion of these febrile disturbances can be ascribed to faulty asepsis in examining. Seanzoni has given a reply to this question. He found that in a series of 157 "precipitate" births, of the 97 women who were not touched by any examining finger at all, 21.6 per cent. had a rise of temperature to between 102° and 104° F. Again, among 112 women who were delivered without any contact from without, 17 had fever which could be attributed to causes other than puerperal infection, and 11.5 per cent. a rise of temperature, up to 102.5° F., presumably from infection. Hofmeier regards these cases as proving that the parturient woman can infect herself. The doctrine of *noli me tangere* is therefore not trustworthy, and we have to consider in obstetrics the sin of leaving undone those things which we ought to have done as well as of doing those things we ought not to have done. Hofmeier teaches careful disinfection of the hands and cleansing of the external parts of the patients—things we ought to do. More difficult to determine is whether disinfection of the internal parts should be left undone. If the infection is due to the flora of the vagina, then internal disinfection should be recommended, but experience is scarcely encouraging. If the infection is due to the intrusion of external bacteria, then Hofmeier's experiment of applying a mercury perchloride compress to the external parts should have lessened the morbidity, but it did not. Practice and not theory must settle the point, and it is to the obstetricians that the profession must look for a method which will safeguard

women from all forms of puerperal infection. In spite of the excellent results *quoad vitam* which have been achieved, the fact that fever still continues to attack a certain percentage of lying-in women proves that the ideal conditions have not yet been discovered, but at present it would seem that the woman herself is her own worst enemy.

RESEARCH DEFENCE SOCIETY.

IT is just a year since we published a letter from the Earl of Cromer announcing the formation of a society whose function it should be "to make known the facts as to experiments on animals in this country: "the immense importance to the welfare of mankind "of such experiments; and the great saving of human "life and health directly attributable to them." At that time the society had been in existence for some three months, and already numbered more than 800 members. Since then its membership has increased to 2,270, and branches have been formed in Birmingham, Bournemouth, Brighton, Cambridge (University Branch), Dublin, Edinburgh, Leeds, Liverpool, Manchester, Norwich, Oxford, Shrewsbury, Torquay (Devon Branch), York, and in other places. A number of lectures have been delivered under the auspices of the society, which has also published pamphlets and leaflets giving information to all who ask for it as to experiments on animals and their results.

We congratulate the energetic secretary, Mr. Stephen Paget, on the work of the society, and especially on a new enterprise by which its activity is displayed. A selection of its publications has just been issued in book form.¹ The volume, which is beautifully printed, contains, in addition to a preface, the address given by Lord Cromer at the inaugural meeting of the society held on June 19th, 1908; a summary of the report of the Inspectors on Experiments on Animals made during 1907 in Great Britain and Ireland; and some facts as to the administration of the Act taken from evidence given before the Royal Commission on Vivisection. Professor Starling deals with the use of dogs in scientific experiments, showing that for a large number of important researches that animal is indispensable, owing to its size and the marked analogy of its digestive system to that of man. Practically the whole of our knowledge of the production of lymph in the body is derived from experiments on dogs. For our knowledge of the causation of the heart sounds and their interpretation, for the investigation of the pulse, of the work of the heart, and of the relations between the blood pressures and the heart, and the blood vessels respectively, we are also indebted to experiments on the same animal. Observations on dogs furnish the key to the laws governing the movements of the intestines. Our conceptions of the process of digestion, which must guide physicians in the treatment of its disorders, have been revolutionized by experiments on dogs. Professor Starling says that although he has been engaged in the experimental pursuit of physiology for the last seventeen years, he has never seen pain inflicted on a dog in a

¹ Publications of the Research Defence Society, March, 1908–March, 1909. Selected by the Committee. London: Macmillan and Co., Limited, St. Martin's Street, 1909. (Pp. 216.) It may be mentioned that four pamphlets, included in the volume, were not among the loose set of pamphlets sent to every member of the society last summer. These four pamphlets will now be sent to every member. (We are asked to state that the volume may be procured by members at cost price—1s. 8d., including postage—on application to the Secretary, at 70, Hayley Street, W.)

physiological laboratory in this country. He points out further how pain would defeat the purpose of the experimenter. As he tersely puts it, "A physiological experiment which is painful is thereby a bad experiment." The use of anaesthetics in experiments on animals is illustrated by the evidence given before the Royal Commission by witnesses of acknowledged authority on the subject. The evidence given by Lord Justice Fletcher Moulton before the same Commission, an abstract of which was published in the *BRITISH MEDICAL JOURNAL* of March 21st and 28th, 1908, forms a most important section of the book; coming from a man of legal training and judicial mind, it is perhaps the most striking testimony that has yet been given as to the value of vivisection. Professor Cushny shows how accurate knowledge of the action of drugs has been obtained by experiments on animals; and the value of antitoxin in the treatment of diphtheria is proved by the statistics of the Metropolitan Asylums Board Hospital and of those of New York City and Paris. Dr. A. Gardner Robb, of Belfast, gives a number of facts showing the value of antimenigitis serum (Flexner and Jobling) in the treatment of epidemic cerebro-spinal meningitis. The American figures show a reduction of mortality by more than one-half since the use of the serum. Dr. Gardner Robb's own experience has been that of 275 unselected cases under his care in the Belfast Fever Hospitals before the use of the serum, 72.3 per cent. died; while of 98 cases treated with the serum, only 29.6 per cent. died. An article by Dr. Bashford on advance in knowledge of cancer is reprinted from *Nature*. Professor Osler's evidence as to yellow fever and malaria is next given, and the book ends with an essay on the extinction of Malta fever by Sir David Bruce, in which the story of this triumph of the experimental method is told in a clear and convincing manner.

We strongly recommend this collection of facts as an antidote to the fictions sedulously propagated by the antivivisectionist societies. It should be carefully studied by all who wish to be well posted in regard to matters which, by many even of the household of medicine, are too often taken for granted or treated with indifference. Every one who stands for medical science within his own sphere, however small it may be, is liable to be called upon to give a reason for the faith that is in him; in this little book he will find the fullest justification of animal experimentation as applied to the art of healing, and an exposure of the fallacies of those who denounce that method of research. To those who take part in newspaper controversies or public debates on the subject it is indispensable. It appeals to the public perhaps even more than to the profession; the case for vivisection is put in a manner so simple and lucid that the book is especially suitable for the enlightenment of lay persons who are able to appreciate evidence, and whose mind's eyes are not blinded to plain facts by prejudice, or what theologians call "invincible ignorance." We commend it most earnestly to our readers, not only for their own edification, but as a means of helping them to dissipate error and spread the light.

THE Bristol City Council decided on April 20th to contribute, in the proportion of one penny in the pound on the rates, towards the support of the projected university for Bristol and the West of England. This rate will yield about £7,000 a year.

THE PRIEST AND THE PHYSICIAN.

At a meeting of the Church Medical Union held on April 19th, Mr. W. R. Fisher, who was in the chair, said that the movement which the Union had started might be defined as the co-operation of the Church and the medical profession in the healing of the sick. Mr. Geoffrey Rhodes, the Secretary of the Union, speaking on "Medicine and the Church," said that the discoveries of psychology showed that mind and body reacted on one another. In considering the question of mental healing, a sound conclusion was most likely to be reached if the lines of careful theological study and close scientific research were followed. These they would get in the deliberations of their spiritual leaders and medical men. There was a danger of people being led off the track by unqualified healers. They were not to neglect natural means in the hope of a miracle being performed. They were bound to consider themselves humbly as students, but they could express firm belief in the vital principle that the doctor of medicine and the clergyman should work in all cases in the closest consultation. From the general tenor of the speeches we get the impression that the main object of the Union is to show that the Church has a ministry of healing which can beat Christian Science on its own ground. The Union is especially anxious to reassure the doctors that it intends to work in co-operation with them, not to supplant them. We have no doubt of the excellence of the intentions of the promoters of the movement, but their notions of the end they have in view and of the means by which they are to reach it seem to be vague to the degree of mistiness. The discovery that mind and body react on each other, which Mr. Geoffrey Rhodes attributes to psychology, dates from a very early period in the history of medicine. Thousands of years ago the liver was believed to be the seat of courage, the spleen of depression, the bowels of compassion, and the heart of affection. The old physicians well knew the good effect on the mind of remedies that expelled the "black bile" which produced melancholy, and of laughter which "despopulated" the spleen. Modern faith healing has really added nothing to the knowledge of this kind possessed from immemorial antiquity. Enlightened practitioners of medicine will welcome such help as clergymen can give in ministering to a mind diseased; but it must be on the clear understanding that the care of the body belongs wholly to the doctor. We go further and say, with special reference to the "close consultation of the minister of the gospel and the doctor of medicine" which Mr. Rhodes thinks necessary, that the doctor may be willing to advise the minister when the circumstances of the case seem to call for it, but if he is to do his duty to his patient he cannot consent to meet a clergyman or a spiritual healer in consultation. The course of the Emmanuel movement in America is enough to show that there is a danger that the close alliance with the medical profession which the Church Medical Union professes to desire may easily be used as a means of "covering" unqualified practice.

POOR LAW MEDICAL OFFICER AND A CORONER'S JURY.

AN inquest was held at West Hartlepool by the Coroner for the Stockton Ward District of the County of Durham with regard to the death of a retired master mariner, 69 years of age, who after attending a football match was taken ill in the street and died in a few minutes. It appeared from the evidence given by the police, as reported in the *Newcastle Chronicle*, that as soon as possible after their attention had been directed to this case one of their own

officials took upon himself to communicate with the district Poor Law medical officer by telephone and request his attendance on the patient, but as he declined to be responsible for any remuneration his request was not met. This led to one of the jury remarking that the doctor had evidently refused his services on the question of pay. The jury, after hearing medical evidence, returned a verdict that the death was due to apoplexy—that is to say, from a natural cause—but this non-criminal verdict was accompanied by the following rider: "We desire 'to express our disapproval of the conduct of the 'parish doctor in refusing to attend this urgent case 'unless guaranteed a professional fee.'" How the coroner could have allowed such an opinion as this to be incorporated with the verdict we are quite at a loss to understand. We are not surprised at the jury, unacquainted as probably most of them were with the rudiments of the law bearing on the case, being anxious for this addition to the verdict—no doubt from a desire to be, or to appear to be, charitable, though not at their own expense. The coroner, however, must have known, or, at any rate, ought to have known, that any such censorious rider was no part of the duty of his jury, and that it ought not to have been recorded. It was the duty of the jury to return a criminal verdict if such was justified by the evidence given; but if this could properly not be done, their duty was then at an end. It is true that the coroner in his remarks attributed the incident to "the red-tape 'arrangements of the Poor Law system,'" but we see no account of the Poor Law medical officer in question having been present at the inquest, and therefore assume that he was unjustifiably censured in his absence, without having had any opportunity to defend his own action—a proceeding not sanctioned in any other court of justice, so far as we are aware, in any part of the United Kingdom. The jury, in fact, had no right to express their disapprobation of the conduct of any individual. To do so was unquestionably *ultra vires*, and it is quite possible that mischief or hardship may result from it elsewhere.

INTESTINAL BACTERIA.

PROFESSOR METCHNIKOFF¹ regards it as a settled point that amongst the inhabitants of the large intestine there are three important types of putrefactive bacteria—namely, *Bacillus putrificus*, *Bacillus sporogenes*, and *Bacillus welchii*. With regard to the pathogenic powers of these three types opinions differ, the bacillus of Welch, often known as *Bacillus aerogenes capsulatus*, being apparently the one with which disease is most frequently associated. In experiments on guinea-pigs Metchnikoff found that the *Bacillus welchii* presented remarkable variations. When freshly obtained from pus or from the intestinal contents, it rarely possessed a marked degree of infectivity, and the guinea-pigs usually resist considerable doses inoculated intraperitoneally. But the bacillus readily gained in virulence; after a few passages it acquires an extremely high pathogenicity, and produced death in the guinea-pigs within one or two hours after introduction into the peritoneal cavity. A young chimpanzee, however, was made to ingest large quantities of *Bacillus welchii* without suffering the slightest ill effects. With a view to investigating the production of toxins by the three types of putrefactive intestinal anaerobes mentioned, Professor Metchnikoff cultivated them *in vacuo* in a medium consisting of finely minced meat and water. Under these conditions toxins were produced, the effects of which were tested upon rabbits, generally by intravenous inoculations and sometimes

by introduction per rectum. The material introduced consisted of the filtered liquid portion of the culture medium; in some experiments the liquid was heated to 100° C., and in others it was not heated, but was passed through a Chamberland filter. The most markedly toxic effects were produced by young cultures, aged from two to five days. With older cultures the toxicity progressively diminished, probably owing to the decomposition of the toxins by the action of the bacteria themselves. This explanation is supported by the observation that the liquid which was freed from microbes by heat or filtration preserved its toxicity for a prolonged period. The intoxication manifested itself in a manner which varied according to the dose. When young or adult rabbits were injected with a dose of 7 or 8 c.cm. per kilo. of body weight, death was generally almost instantaneous; the animal fell, there were some clonic convulsions, and respiration and the cardiac movements ceased. With smaller doses the animals remained alive for three or four hours, and then died in the same condition as the former. When the less toxic liquids were employed the rabbits did not die for several days, and after small doses they remained alive for months, or even indefinitely. In the acute type of intoxication the liver, the kidneys, and the small intestine were very hyperaemic, and, like the heart, filled with non-coagulated blood. The results of the experiments emphasized very clearly the extreme variability in the toxicity of different putrefactive anaerobes. Of the three species studied the *Bacillus welchii* was found to be the most active. But the difference between its toxicity and that of the two other microbes was not very considerable. In one case the bacillus of Welch, isolated from a severe case of appendicitis, proved almost innocuous as compared with other cultures of the same microbe, derived from persons in good health, which produced rapid death in the experimental animals. Rectal injections of the toxic liquids produced most effect on small rabbits; those which received one or more doses of the bacterial products failed to develop like normal animals, and some of them died. Another point noted by Professor Metchnikoff is that the liquids obtained with faecal material inoculated in a meat medium are much more toxic than the liquids derived from a vegetable decoction inoculated with the same material. Professor Metchnikoff's observations on proteid decomposition by intestinal bacteria are of interest, but the data which he provides are not sufficient to enable us to express an opinion as to the precise significance, theoretical or practical, of his researches.

TREATMENT OF TETANUS.

REFERENCE has already been made to an instance reported from Ann Arbor, Michigan, of tetanus developing on the twelfth day after dilatation and curetting of the uterus, with shortening of the round ligaments after Alexander's method;¹ but some further particulars of the case and of the treatment successfully adopted will be of interest. The patient was an unmarried girl aged 19, subject to dysmenorrhoea, and Dr. Reuben Peterson operated in a private hospital with an aseptic technique. Stiffness and soreness about the jaws appeared during the twelfth day, and double parotitis with hysteria was suspected. For two or three days the stiffness was trifling, but on the fourth acute tetanus with marked opisthotonos developed. Dr. Peterson called in consultation Dr. W. H. Hutchings of Detroit, who had successfully treated 5 cases of tetanus by chloretone, 3 being

¹ Ann. de l'Inst. Pasteur, December, 1908.

¹ Amor. Journ. Obstet., April, 1909, p. 658.

had "Fourth of July accidents" from fireworks or pistol shots. Dr. Hutchings administered to Dr. Peterson's patient an enema of 60 grains of chloretone dissolved in hot olive oil. The spasms of the jaw and back relaxed, and the patient seemed comfortable but drowsy, as though under opium. Then Dr. Peterson administered 1,500 units of the antitetanic serum, the benefits of which to patients after the development of the spasms seem to him doubtful. Early next morning the spasms recurred. An enema of 60 grains of chloretone was once more administered, the dose of antitetanic serum was repeated, and the convulsions ceased altogether. The highest temperature reached was 100.2° in the rectum, the highest pulse-rate 114. After the second dose of serum and chloretone convalescence was uninterrupted. As already stated, Dr. Peterson failed to discover the origin of the perilous complication in his case. The catgut employed for the plastic operation on the round ligaments was tested by an expert with great care and found free from germs. A minute blister had developed at the corner of one incision, which had otherwise healed well. The serum in the blister contained the staphylococcus, but the tetanus bacillus could not be isolated. Dr. Peterson notes that this is the sixth of Dr. Hutchings's cases of tetanus, serious like all the others, and that, like them, recovery followed the administration of chloretone, which is trichlor tertiary butyl alcohol, sometimes called acetone-chloroform. Others may be inclined to award some of the merit to the antitetanic serum.

THE INFLUENCE OF HEREDITY AND ENVIRONMENT ON EYESIGHT.

In a memoir¹ recently issued, Miss Amy Barrington and Professor Karl Pearson deal with some interesting problems of inheritance in man. They find, by the use of exact statistical methods of analysis, that there is strong reason for believing that errors of refraction and keenness of vision are heritable characters, although the fact that most of the material is selected renders an exact evaluation of the statistical constants difficult. From the medical standpoint, perhaps the most interesting section of the paper is that dealing with the influence of school life on vision. In the course of a very careful examination of the evidence adduced in support of the popular belief that attendance at school is highly prejudicial to the eyesight of the rising generation, the authors point out that no such conclusion can be regarded as well established. They find that the coefficient of correlation between degree of myopia and age is 0.33 ± 0.019 , between degree of myopia and years at school, 0.244 ± 0.020 (Cohn's data). In commenting on these values they state that they show "that the associations between "degree of myopia and age and degree of myopia and "years of school life, while quite sensible, are not by "any means very marked. Further, whichever "test be applied it indicates that the relationship between age and degree of myopia is "closer than that between the latter and the "number of school years. In fact, a correlation of 0.8 "to 0.9 between age and number of years of school life "would make the association of degree of myopia and "years at school for a constant age practically zero. "Cohn provides no data by which we could determine "this correlation of age and school life for his material. "But in the London schools the children practically "rise a standard a year, and it has been found by "Mr. Heron that the relationship of standard and age

"is practically of the above magnitude. Accordingly, "Cohn's statistics seem to indicate that the moderate "association they exhibit between school environment "and degree of myopia is solely a secondary result of a "primary relation between age and degree of myopia. "This increase of myopia with age may be due to the "continued action of some environmental factor or to "a growth factor. Cohn's statistics, however, do not "demonstrate, as has been assumed by many "ophthalmological writers, that school is the hot "bed for the production of myopia." In view of the numerous imperfections of existing data, the authors are to be commended for their caution in drawing conclusions with respect to this important matter; we think that their results show that in the anthropometric school laboratories, that may some day be established, ophthalmological measurements should be collected with at least as much zeal as information regarding weight, height, and chest dimensions. Among other curious results, the authors find that normal vision is slightly correlated with overcrowding, bad economic conditions, and morally defective parentage. They ask: "Can it be that "these bad home conditions keep the children in the "streets, and so relatively away from the bad "environment and in relatively fresher air?" A perhaps equally plausible hypothesis is that with these unfavourable environmental conditions only the relatively fitter members of the stocks survive infancy, but we do not think the question can be solved from existing data. This memoir deals with questions of such interest, both to the medical man and publicist, that it deserves a wide circulation; and it can be studied with advantage even by those not versed in statistical methods, since technicalities of biometry are in it reduced to a minimum.

THE SUCKLING OF INFANTS.

THE complaint that mothers of the present day cannot nurse their babies has during the past few years been shown to be unfounded. Medical men know on the evidence of practical experience that attempts to suckle seldom fail if made in accordance with scientific teaching and carried out with a reasonable amount of perseverance. The work of the late Professor Budin in Paris clearly shows how great is the importance of proper attention to this subject, and those who are interested in the matter cannot do better than study a very able article by Dr. Janet Lane-Claydon which appears in the January number of the *Nineteenth Century and After*. In Germany the pioneer of the movement was Dr. Oppenheimer, and the consultations at which mothers are given advice and assistance with regard to the management of their babies have been instrumental in preserving the health of large numbers of babies. Dr. Vidal, of Darmstadt, has during the past three years followed the example of Budin and Oppenheimer, and has published recently a brief account of his results.¹ It is not, he finds, sufficient to instruct the mothers during the lying-in period to suckle the babies. As soon as the doctor's back is turned, the mother, the grandmother and the neighbours give their advice; all the scientific teaching is thrown away, and the baby gets a bottle. The amateur counsellors probably do not know that in the "good old time" 30 per cent. of their infants died. Dr. Vidal states that vanity and comfort are rarely taken into account by the German woman. Usually she is over-anxious, and believes that she has not enough milk to satisfy the infant. She complains that the child cries so much. The mothers are taught at the consultations that the act of sucking causes the

¹ *A First Study of the Inheritance of Vision and of the Relative Influence of Heredity and Environment on Sight*. By Amy Barrington and Karl Pearson. P.R.S. Eugenics Laboratory Memoirs V. London: Dulau and Co. 1909. (Pp. 61. 4s.)

¹ *Muench. med. Woch.*, January 12th.

flow of milk, and if a baby is given a bottle it will refuse after a time to suck at its mother's breast when it can get milk with less trouble. This is the chief danger of the so-called *allaitement miaté*. During the three years Dr. Vidal has only had to tell one mother that she had not enough milk. He was able to compare the infants brought to the consultations, who did well without exception, with those managed according to amateur advice, of whom no small percentage died. He gives examples of the advantages of the consultations to mothers who had lost child after child from diarrhoea before they were taken in hand. At times the first attempts to make the baby take the breast are difficult; an infant may even refuse to suck for a whole week, and the mother and the midwife are very apt to lose patience. The same answer which can be given to the assumption that the quantity of milk is insufficient may apply to the assertion that the milk is poor in quality. Neither the mother nor the midwife has any conception with regard to the normal quality of mother's milk, and the best proof that the milk is good and sufficient is to be found in the fact that the baby thrives on it. This Dr. Vidal has been enabled in each case to demonstrate to the mothers at his consultations. The results which he has obtained, therefore, tally with those obtained in Paris and elsewhere where similar consultations have been organized. The saving of life and the diminution of days, weeks, and months of sickness are so striking that we do not hesitate to say that one of the most important reforms in hygiene called for at the present time is the institution of places where mothers may bring their healthy babies for inspection and where advice and assistance in the matter of the proper management and care of the infant are provided.

WIRELESS TELEGRAPHY.

THOUGH no workers can point with greater pride to their results, it is the fate of legislative and scientific labourers in the field of occupational disease to be unable ever to claim for long a shrinkage in the extent of their sphere of action. Occupational mortality decreases steadily, no doubt, year by year, but the general mass of occupational disease exhibits something of the vitality of an amoeba. So soon as skilled investigation has diminished the risks of those engaged in one special trade and one evil is thus repressed, advances in scientific knowledge, and the occupations or manufactures which develop as a sequence, lead to the extrusion of a new pseudopodium and thus bring up the total amount of trade or occupational disease more or less to its former level. The latest claimant to consideration in this connexion is wireless telegraphy, its sponsor being a medical officer of the French navy, Dr. Bellile. During the recent troubles in Morocco wireless telegraphy was constantly being used on board his ship, and among the men under his charge he found lesions explicable only on the supposition that they were due to this new employment. For the most part, they consisted of conjunctival irritation, more or less intense in character, sometimes not easy to cure, and in one or two instances followed by corneal ulceration. One of the patients developed also a patch of eczema near the eye, another a patch of eczema on his wrist, and these skin troubles were, Dr. Bellile considers, not merely coincidental but of the same etiological significance as the conjunctivitis. In view of the intensity of the flashes emitted when wireless telegraphy is in progress, there is no difficulty in believing that conjunctivitis may be set up among the operators; fortunately, however, the remedy suggested by Dr. Bellile is equally easy—namely, the

wearing of blue or other glasses calculated to protect the eyes from the effect of the ultra-violet and other rays emitted. He is, however, much less convincing when he suggests that the emission of these flashes of electricity may have a general morbid effect on every one anywhere in their vicinity, and not merely be productive of occasional lesions on the exposed parts of the bodies of actual operators. Neurasthenia and allied nerve troubles he holds to be much more frequent in the French navy than formerly, and he suggests as a cause the increasing use of electricity. Far be it from any one to dogmatize on the capabilities of electricity, but it should not be forgotten that, though wireless telegraphy entails the launching into space of an immense amount of electrical force, this is taken up by the creation of Hertzian waves. Hence the analogy which he draws between wireless telegraphy and x-ray work would seem to be somewhat faulty. Much simpler reasons could probably be suggested for an increase in functional nerve troubles among men living and working on modern war ships than that of the introduction of this new use of electricity.

THE LEPERS OF MOLOKAI.

MUCH has been heard in recent years of the wretched conditions of life in places where lepers doomed to separation from their fellows are herded together, and appeals to popular feeling have been founded on such statements with the object of bringing about a reversal of the policy of segregation. It is satisfactory, therefore, to learn from an unprejudiced witness the actual facts in regard to one of the best-known leper settlements. Mr. Jack London, in a recent issue of the *Contemporary Review*, has stated, as the result of a visit to the place which must always be associated with the name of the heroic Father Damien, that the horrors of Molokai as they have been painted in the past do not exist. The settlement, he says, has been written up repeatedly by sensationalists who have never set eyes on it. The fact that a leper is unclean, however, should be insisted upon; and he gives it as his opinion that, from what little is known of the disease, the segregation of lepers should be rigidly maintained. In order to dispel some of the popular misapprehensions as to leprosy, he describes scenes which serve to show the relations existing between the lepers and non-lepers at Molokai. On the morning of his arrival, Mrs. London and he attended a shooting match of the Kalaupapa Rifle Club. Among the members of the club are Dr. Goodhue and Dr. Hollmann, the resident physicians, who live in the settlement with their wives. Lepers and non-lepers were using the same guns, and all were rubbing shoulders in the confined space. The majority of the lepers were Hawaiians, but in the stand directly in front of the visitors was an American who had fought on the Confederate side in the Civil War. He was 65 years of age, but that did not prevent his running up a good score. Strapping Hawaiian policemen—lepers, khaki-clad—were also shooting, as were Portuguese, Chinese, and *kokuas*, the latter being native helpers in the settlement, who are non-lepers. On the afternoon that Mr. and Mrs. London climbed the famous *pali*—a cliff from 2,000 ft. to 4,000 ft. high, which separates the place set apart for the lepers from the rest of the island—and looked their last upon the settlement, the superintendent, the doctors, and the mixture of nationalities and of diseased and non-diseased were all engaged in an exciting baseball game. Terrible and monstrous as was the treatment of the leper in the Middle Ages, it taught the great lesson of segregation. By its means leprosy was stamped out. And by the same means, according to Mr. London, leprosy is even now decreas-

ing in the Hawaiian Islands. But he insists that the segregation of the lepers on Molokai is not the horrible thing which has been so often exploited by Yellow writers. In the first place, the leper is not torn from his family. When a suspect is discovered, he is invited by the Board of Health to come to the Kalihi Receiving Station at Honolulu. His fare and all expenses are paid for him. His case is first adjudicated upon by means of microscopical examination by the bacteriologist of the Board of Health. If the *Bacillus leprae* is found, the patient is examined by the Board of Examining Physicians, five in number. If found by them to be a leper, he is so declared, and this finding is later officially confirmed by the Board of Health, and the leper is ordered to be sent to Molokai. Furthermore, during the thorough trial that his case is given, the patient has the right to be represented by a physician whom he can select and employ for himself. Nor, after having been declared a leper, is the patient immediately rushed off to Molokai. He is given ample time—weeks, sometimes even months—during which he stays at Kalihi and arranges his business affairs. At Molokai, in turn, he may be visited by his relatives, business agents, etc., though they are not permitted to eat and sleep in his house. Visitors' houses, kept "clean," are maintained for this purpose. When at Molokai, the declared leper has the privilege of re-examination. The settlement of Molokai has a far more delightful climate than even Honolulu, being situated on the windward side of the island in the path of the fresh north-east trades. The scenery is magnificent; on one side is the blue sea, on the other the wonderful wall of the *pali*, receding here and there into beautiful mountain valleys. Everywhere are grassy pastures, over which roam the hundreds of horses owned by the lepers. While not attempting to disguise the fact that leprosy is a terrible disease, Mr. London says that he would prefer to spend the rest of his days in Molokai than in any tuberculosis sanatorium.

CENSORSHIP IN RUSSIA.

THERE is at least one thing in regard to which Russia is in advance of any other country. The Government seems to be resolved that the people shall not be deluded by quackery. It is announced that advertisements of medicines are henceforth to be subjected to strict censorship in Russia. All advertisements concerning medicines, appliances (cosmetic and hygienic), the practice of medicine, dentistry, midwifery, massage, pharmacy, etc., and watering places and mineral wells, must be submitted to the Censor before they are inserted in a newspaper. Once passed by him, no modification will be allowed. It is forbidden to advertise abortifacients or preventives of conception, and to publish lying or exaggerated praises of medicines of any kind. The law also precludes the advertisement of products or preparations which can be sold only under a name that implies an indication of their use, such as "antibrigitin" or "antirheumatin"; these we think it well to state are, as far as we know, purely imaginary names which we use to denote the kind of thing we suppose to be meant. The advertisements of doctors must contain no comment. In doubtful cases the question must be referred to the principal medical inspector.

THE HEIGHT OF CREDULITY.

A GERMAN professional paper lately related an example of ingenious enterprise on the part of a former student of pharmacy aided and abetted by a friend. They inserted the following advertisement in a number of

journals: "At last means have been found to increase 'the height of the human body. We guarantee to all 'who will use our apparatus, *Werde gross*, that in 'two days' time they will stand at least 4 cm. higher. "We will pay 1,000 marks to every purchaser who has 'failed to obtain the promised result." The advertisement ended as follows: "Ladies and gentlemen, such "a guarantee is given only by him who can speak "with absolute certainty as to the result. The "price of the apparatus is 5 marks. Address," etc. A number of simpletons fell into the trap and sent their 5 marks, getting in exchange a pair of cork soles 4 cm. in thickness, accompanied, by way of adding insult to injury, by a bottle of hair lotion and a collyrium. We confess we do not see the special significance of the hair lotion, having no reason to believe that bald people are bigger fools than their neighbours. But there is a subtle touch in the collyrium which, it may be presumed, was intended to suggest that the eyes of the poor dupes required some attention. The advertisers may have taken a hint from Swift's lines on himself:

He left the little wealth he had
(To build a house for fools and mad;
Thus showed by one satiric touch
No nation wanted it so much.

Unfortunately for our adventurers, the police with its inquisitorial ways bestowed an inconvenient attention on their enterprise. The end of the affair was that one was fined 300 marks, the other 50. If they were of a philosophic turn of mind, however, they must have felt it cheap at the price to show once more the infinite gullibility of the average man.

DR. J. LUCAS-CHAMPIONNIÈRE, President of the International Society of Surgery, will deliver the annual address to the Cardiff Medical Society on Friday, June 4th. The subject selected by the eminent French surgeon is the modern treatment of fractures.

THE Prince and Princess of Wales will open the Edgar Allen Library of the University of Sheffield on Monday next, and will attend the Congregation in the Fifth Hall of the University at which the Chancellor, the Duke of Norfolk, E.M., K.G., will confer honorary degrees.

IN referring last week to the election of the late Mr. C. G. Wheelhouse to the Council of the Royal College of Surgeons of England in 1876, the belief was expressed that he had been preceded by only two provincial Fellows, Mr. George Southam of Manchester, and Mr. Alfred Baker of Birmingham. Mr. G. C. Franklin informs us, however, that Mr. Thomas Paget of Leicester was elected a member of the Council in 1862, and that he was the first provincial surgeon to receive that honour.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

THE House of Commons reassembled after the Easter holidays on Monday last. There was only a moderate attendance of members, and instead of the usual three score or more questions only six appeared on the paper, and of these only three were asked. Two related to the remarkable speech of Admiral Smith-Dorrien with reference to the body of the late Prime Minister, and the First Lord said in reply that the reference was not intended seriously, and he expressed regret on behalf of the gallant admiral that the reference had been made.

The London Elections Bill was then introduced by Mr. Lewis Harcourt, and after a speech in opposition from Sir F. Banbury was read a first time. The Indian Councils Bill was next taken in Committee, and occupied the rest of the sitting.

The Admission of Strangers.—It is now several months since the suffragette disturbances led to the closing of the galleries for men and women in the House of Commons. A Committee of the House was appointed to consider the course to be adopted in the future, and the bill, called the Houses of Parliament Bill, which embodied their recommendations, occupied the attention of the Commons for some hours on Tuesday afternoon. The bill proposed to make disorderly conduct an offence, for which any stranger could be arrested by an officer of the House, locked up, and on conviction before a magistrate be sentenced to six months' imprisonment or a fine not exceeding £100. In the course of the discussion, it soon became apparent that the members of all political parties disliked the police-court procedure, and felt that the House itself ought to be the guardian of its own order and comfort. There were also unmistakable signs that a large number of members were quite content to leave the galleries empty for the present. The bill was severely criticized by Sir E. Carson, and after the Attorney-General had said the Government would let members vote as they like, and not make the Bill a Government question, the Prime Minister finally settled the matter by moving the adjournment of the debate. This was carried *nem. con.*, and so for the present the bill disappeared, to the great satisfaction of the House. *Solvitur risu tabula.*

The Housing Bill.—Sir Walter Foster has put down amendments to Clause 67 of this bill, to give district and borough medical officers of health the same security of tenure as county officers, and to place all medical officers of health on an equality as regards the duration of their appointments.

The Anaesthetics Bill, or, as it is officially called, the Medical Acts Amendment Bill, is exciting a good deal of criticism in many quarters. The registered dentists as well as the unregistered dentists are very active against it. Registered dentists and students of the dental schools ask that properly qualified registered dentists should be allowed to give anaesthetics, and that the use of local anaesthetics should be included in the scope of the bill. The bill has been blocked by no fewer than seven members.

The Local Education Authorities (Medical Treatment) Bill of Mr. Walter Guinness (see SUPPLEMENT, p. 191) would enable Local Education Authorities to recover the cost of the medical treatment of children, where such treatment is provided under Section 13 of the Education (Administrative Provisions) Act, 1907. Local Education Authorities already have power to recover the cost of meals from parents under the Education (Provision of Meals) Act, 1906. Parents who neglect to provide necessary medical aid are liable to conviction under Section 12 of the Children's Act of 1908, but there is no power to enable the local authority to recover the cost of treatment.

The Asylum Officers' Superannuation Bill, which passed a second reading before Easter, and was referred to a Select Committee, had its Committee appointed at the commencement of public business on Monday last as follows: Sir W. Collins, Mr. Hazleton, Mr. I. M. Henderson, Mr. Horniman, Mr. W. E. B. Priestley, Mr. T. F. Richards, Mr. Walter Roch, Mr. Stanier, and Sir John Batty Tuke.

Milk Supply in Egypt.—Mr. John Robertson asked the Secretary of State for Foreign Affairs on Tuesday whether, in view of the high death-rate in Egypt, he would urge upon the Egyptian Government the necessity of establishing a system of inspection of cowsheds and dairies, and milk cans coming by train. Mr. McKinnon Wood said that it was a question of internal administration on which there did not appear to be grounds for interference on the part of His Majesty's Government.

MANCHESTER AND DISTRICT.

THE CHILDREN'S HOSPITAL PROBLEM.

ACCORDING to the annual report of the Manchester Children's Hospital recently issued, the pressure in the out-patient department on the staff and the accommodation has so increased of late as to constitute a serious problem. Altogether apart from the increase in the population of the area supplied by the hospital, there seems to be a growing tendency to resort to such institutions on the part of many who formerly would have made other provision. The fact is mentioned that the hospital was represented at the conference of hospital authorities convened by the British Medical Association in London about a year ago; as the outcome of the suggestion there made, changes have been introduced with a view to checking possible abuses of the charity by persons well able to make other provision for their sick children, for there was a strong feeling that such abuses had had the effect of deterring people from supporting the hospital as they otherwise would. The ordinary expenditure for the last year amounted to £11,079, which was £378 less than the income. The balance owing to the bank was £1,711 on the income account. The beds at the Pendlebury Hospital had always been kept well filled, while, as far as the dispensary was concerned, the past year provided the hardest and busiest year's work that the medical and nursing staff had ever had; even the new building with all its accommodation had on busy days been insufficient for their needs. The operations performed at the dispensary had risen from 486 in 1906 to 871 in 1907 and to 1,303 in 1908. This great and constant increase was due in large measure to pressure put upon parents by the school medical inspectors to have their children attended to. The report draws special attention to the deaths among children from diseases of the lungs, and continues:

The massacre of the innocents hangs over our city like a moral black cloud, and that it is in part due to the physical black cloud which also hangs over us no one will doubt who studies our statistics and sees the figures relating to deaths from diseases of the lungs. And it should be remembered that for every child that dies from bronchitis, fully a hundred are by it deteriorated in constitution and physique, and rendered less able to resist disease in whatever form it may attack them.

There can be no doubt that the hospital is faced by a difficult problem which will have to be solved in the near future. On the one hand, the education authorities are pressing more and more for specialist treatment for the school children which in many cases general practitioners will not undertake except at a fee which the parents consider to be prohibitive. Parents who could afford to pay ordinary fees for general medical treatment, and who would be ineligible for free hospital treatment of a general kind, profess themselves, not without reason, unable to pay two guineas for removal of adenoids with the necessary anaesthetic at home. Theoretically such cases are suitable for the hospital, but their great number is taxing to the uttermost the power of the staff and the accommodation of the hospital. The suggestion has been made, quite unofficially, that the Education Authority should subsidize the hospital for the extra work it is doing for the community. But two objections are raised against this—first, that it is on the staff itself that the extra work falls, and it would be unreasonable to impose public work on them without personal remuneration. If this be done, the payment for each case would necessarily be small, and the amount paid might gradually come to be regarded by the public as the standard fee. In the second place, seeing that the hospital provides the accommodation, the anaesthetic, and all apparatus, as well as the nursing assistance, the hospital itself would have a claim for a considerable part of the subsidy. But no sooner would it become known that the hospital was being subsidized than at once private subscriptions would begin to fall off. People would refuse to give twice, once through the rates and again by private subscription, and the last state of the hospital would be

more than the first. That all these difficulties are not merely theoretical is shown very plainly by the experience of Sheffield, where the experiment of subsidizing the hospitals has been tried for about a year, and has now been condemned as a failure by the Sheffield Division. Some time ago the Manchester Divisions expressed their entire sympathy with the Sheffield practitioners in their attempt—now likely to prove successful—to terminate the present system at Sheffield, and the object lesson ought to prevent anything similar in Manchester. Meanwhile, until the Education Authorities make some provision of their own, which they are under no compulsion to do, things will have to go on as at present at the Children's Hospital—that is to say, the honorary staff will have to consent to be overworked for the public good, and the hospital will have to continue increasing its rapidly rising deficit unless the subscriptions greatly increase. Another alternative is that the advice given by the school medical inspectors to parents shall be regarded as only the expression of a pious opinion.

LIVERPOOL.

NEW OUT-PATIENT DEPARTMENTS.

The preparations for erecting the new out-patient department of the Royal Infirmary are being rapidly carried forward, and during the last two months the houses which occupied the intended site have been demolished. Apart altogether from the cost of the upkeep of the new department, the destruction of these houses involves a loss to the infirmary of £250 a year in rents. The preparation of the ground is going forward, and the ceremony of laying the foundation stone will be fixed for an early date.

At the Royal Southern Hospital a new out-patient department is also in contemplation. This institution was founded in 1841 under the name of the Southern and Toxteth Hospital, was rebuilt in 1867-72 at a cost of about £55,000, and was opened in May, 1872, by H.R.H. Prince Arthur, Duke of Connaught, when it was named the Royal Southern Hospital. The present extension will occupy a site in Caryl Street immediately opposite the main buildings. The land was acquired and cleared by the committee some years ago in anticipation of the funds necessary for building, and these it is understood are now forthcoming. The cost of a building providing for 50,000 attendances a year will be £8,500, towards which the Corporation of Liverpool is empowered to vote £4,000. There will still be required a sum of £1,200 for furnishing. The new building will be completely separated from the hospital, and will stand on a site measuring 960 square yards. The waiting hall, placed in the middle of the building, will be carried up considerably higher than the surrounding offices, and so enable it to be lighted on the four sides and to have a through ventilation. The building is to be faced with red pressed bricks and stone bands. The construction will be commenced almost immediately, and will be completed in about a year.

TROPICAL SCHOOL EXPEDITION.

Dr. Kinghorn and Mr. Montgomery, who went out to Central Africa on behalf of the School of Tropical Medicine to inquire into the possibility of checking the spread of sleeping sickness in British Central Africa, have just returned to England after a sojourn of nearly two years in those territories. The expedition was the eighteenth sent out by the school, and covered some 8,000 miles on foot, principally in North-Eastern Rhodesia and Nyassaland. The country is mostly a plateau from 3,000 to 5,000 ft. above the sea level. The temperature was not excessively hot, and at times the nights were frosty. The health of Europeans is usually good, and with a little care it is quite possible to avoid the complaints usually found in the tropics, such as malaria, dysentery, and tick fever. The cattle tsetse fly is common and very destructive, but the species which conveys the organism of sleeping sickness has apparently a limited distribution. It does not occur in Nyassaland.

HULL.

PLAGUE AMONGST RATS.

SEAPORT towns in direct communication with tropical ports infected with plague are always liable to infection,

and in most instances this is brought about by the introduction of diseased rats. Dr. J. Wright Mason, Medical Officer of Health for Hull, in a report recently issued, gives an account of such an outbreak amongst the rats in Hull. Dead rats having been discovered in one of the sheds at the docks, some of them were examined bacteriologically by Dr. Thompson, Assistant Medical Officer of Health for Hull, and by Dr. Klein in London. The results were the same in both instances, bacilli resembling those of plague being seen in smears from the organs; these when cultivated and put through the various tests were shown clearly to be true plague bacilli. More dead rats found a fortnight or so later gave similar results, but these fortunately came from the same shed; and as inquiries had been made at all the other docks in port as to the discovery of dead rats, with entirely negative results, this indicated that the disease had remained localized to the original shed. The origin of the epidemic is not far to seek. From December, 1908, to the end of February, 1909, Dr. Mason states that six vessels from suspicious and plague-infected districts—namely, Alexandria and Karachi—had discharged cargo on the south side of that particular dock where the infected shed is situated. The escape of one infected rat from either of these vessels to shore would of course be sufficient. Disinfection of the shed and the destruction of rats has seemed to stamp out the outbreak, and fortunately no human beings have become infected. It will be well, however, to exercise special care for some months to come, as it is just possible that some disease-stricken rats have escaped, and these might spread the infection further.

DEVON.

RESEARCH DEFENCE SOCIETY.

A DEVONSHIRE branch of the Research Defence Society was formed last July. Its list of patrons and officers includes Earl Fortescue (Lord Lieutenant of Devonshire), Hon. W. F. D. Smith, M.P., Admiral Sir Wm. Acland, Sir Thomas Acland, and many other leaders of thought and action in the county. Mr. Eden Philpotts, the well-known novelist, is president of the branch. Mr. W. F. Meres, of Torquay, the honorary secretary, states that the branch has been chiefly recruited hitherto from Torquay and the neighbourhood, but it is his confident hope that he will obtain an accession of strength from all parts of Devonshire. The list of members grows steadily. The Committee has arranged a series of lectures in different centres explanatory of research, and one of these was delivered last week at Exeter, before a large audience, by Mr. Stephen Paget, under the chairmanship of Dr. H. Davy, acting-President of the British Medical Association. The lecture was illustrated by a number of beautiful diagrams. Several antivivisectionists were present and sought to place their views before the meeting, but Dr. Davy, after taking a vote on the question, refused to allow them to do so.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

MEATH HOSPITAL, DUBLIN.

SIR HORACE PLUNKETT, C.V.O., presided at the annual meeting of the Meath Hospital, Dublin, on April 19th. The report showed that the debit balance, which at the beginning of the financial year was £5,610 19s., now amounted to £6,241 6s. 3d. This continued deficiency is a cause of much anxiety to the managing committee, which fears that it may be necessary to close a considerable number of beds; 1,549 patients were treated in the wards. The average daily number of beds occupied was 115.03. The number of accidents treated was 7,890. Sir John W. Moore mentioned that subscriptions had fallen off during the past few years, and in that connexion said that the statement which had been made with regard to that hospital, in common with other Dublin hospitals, that vivisection was practised within its precincts, was a deliberate falsehood. Sir Lambert Ormsby, Mr. C. Lawler, J.P., Mr. W. S. Collis, Mr. P. C. Cowan, and Mr. Arthur Andrews, J.P., also addressed the meeting.

COUNTY CORK SANATORIUM.

The laying of the foundation stone of the new Sanatorium for Consumption on April 14th has caused widespread satisfaction throughout the county of Cork. Her Excellency the Countess of Aberdeen, who has done so much throughout Ireland to assuage the ravages of the "white scourge," travelled from Dublin, at some personal inconvenience, to be present at the ceremony. On arrival at the site, Her Excellency was met by Mr. Arthur McDonald, the Chairman, and the other members of the Joint Hospital Board. On behalf of the Conjoint Board Mr. McDonald presented an address to Her Excellency, in which the Board expressed its sincere appreciation of her kindness in coming to lay the foundation stone of the first county sanatorium in Ireland to be erected and maintained for the treatment of poor consumptives. The address recorded that the Cork Joint Hospital Board was brought into existence over three years ago by a Provisional Order, and was entrusted with the function of establishing and maintaining a sanatorium for poor consumptives of the County and City of Cork. Considerable difficulty was experienced in securing a suitable site that would embrace all the recognized requirements. A little over a year ago, Mr. Langley Brazier-Creagh, a prominent member of the Board, with commendable generosity, offered the site at Streamhill as a free gift, which the Joint Board unanimously accepted, and it met with the approval of the Local Government Board. The funds for the maintenance of the sanatorium were provided by the exertions and influence of the members of the Cork branch of the National Association for the Prevention of Consumption, who succeeded in the unique task of getting all the rural and urban district councils of the county to consent unanimously to levy a rate of one penny in the pound, yielding over £5,000 a year. This, the first county sanatorium in Ireland beginning under such favourable auspices, would, it was hoped, prove a powerful weapon in combating the scourge which had worked such havoc in the country. Her Excellency was then presented by the contractor, Mr. Harbrow, with a silver trowel, and, having duly declared the stone well and truly laid, delivered an encouraging address, commending the action of the County Cork Board to the other counties of Ireland, and urging them to take their share in a fight which was not unto death but unto life. The guests included representatives of the various public bodies of the county and city of Cork, as well as of the Cork branch of the National Association for Prevention of Consumption, and the various Cork branches of the Women's National Health Association. Her Excellency was accompanied by Sir William Thompson, M.D., and Dr. E. C. Biggar, Medical Inspector Local Government Board. A luncheon followed, at which Her Excellency's health was proposed by Mr. McDonald and received with acclamation. Her Excellency replied, and speeches followed by the Lord Mayor of Cork, Mr. Brazier-Creagh, Mr. William McDonald, and others.

The site is situated at the foot of Ballyhoura Mountain, four miles from Buttevant station and eight from Mallow.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

DEATH OF THE REV. DR. SCOTT.

The ecclesiastical history and the ecclesiastical differences in Scotland which have had such a dominating influence in forming the Scottish character are somewhat of a mystery to those who have not lived in that country. In 1843 and for many years afterwards the Church of Scotland was shaken to its foundations by the great disruption, and that it has recovered to its present position is due in great measure to the influence exercised by a number of eminent men. Among them no one in the present day was more highly esteemed than the Rev. Dr. Scott of St. George's, Edinburgh. He was the recognized leader, and to his wise counsel and sound judgement the Church owes much. Dr. Scott died on April 18th, after a long and painful illness due to malignant disease of the prostate.

One of the most conspicuous figures in the Church of Scotland, his death will be widely felt. It is but fitting that our profession, often so closely associated with the clergy, should express its sympathy with the sister profession in the great loss that Scotland has suffered by his death. Dr. Scott took an active interest in medical matters, and was at the time of his death a manager of the Royal Infirmary. Brought into intimate contact with the work of our profession and with many of its members, he showed on many occasions his appreciation of the work done by the medical profession and much sympathy with its members in the difficulties with which they often have to contend. He had the highest respect for the medical profession, and those among its members who knew him personally or by repute held him also in the highest respect, and recognized what a loss this eminent divine must be to the National Church in Scotland.

Hong Kong.

[FROM OUR SPECIAL CORRESPONDENT.]

THE PROPOSED HONG KONG UNIVERSITY.

HIS EXCELLENCY SIR FRANCIS LUGARD has now issued a memorandum setting forth the advantages to be gained by founding a university in Hong Kong, and stating that Mr. Mody, who has promised to erect the university buildings, has made it a condition that a sufficiently large endowment fund must be obtained before he begins the buildings. Mr. Mody at first stipulated that the endowment fund must be raised within six months, but has since signified his willingness to extend the time limit if necessary. His Excellency, in consultation with a committee of those interested in educational matters, has fixed the sum of \$1,000,000 (one million dollars) as the minimum amount necessary for endowing a university whose standard shall be equal to that of the British universities. An appeal asking for generous support of the scheme has been widely circulated, and a large and influential Chinese Committee, having Hon. Dr. Ho Kai as chairman, is at work, and already several large donations have been promised. If the Chinese are really convinced of the advantages of a university in Hong Kong, there is no doubt that the endowment will soon be forthcoming. His Excellency the Governor has worked strenuously in the interests of the proposed university, and it is hoped that his efforts will be successful. Should the university be established, the Hong Kong College of Medicine will cease to exist as a separate institution and become incorporated as the Medical Faculty of the university.

THE OPIUM QUESTION.

At a meeting of the Legislative Council, His Excellency the Governor made a statement in regard to the opium question in so far as it related to the Hong Kong opium divans. As the result of correspondence with the Secretary of State, it had been decided that all the opium divans should be closed by March 1st, 1910. On March 1st this year, twenty-six licences had not been renewed, and the gradual diminution of the licences would give time to provide for supplementing the revenue from other sources. The Imperial Government had promised to help the colony financially in meeting the loss which will result from carrying out its commands.

St. Bartholomew's Hospital and Finchley Cottage Hospital both benefit under the will of the late Mr. Ebenezer Homan, of Friern Hatch, Finchley, the former receiving £1,000 for its Samaritan Fund and the latter £1,000 for general purposes and £500 for its Samaritan Fund.

THE report presented to the annual general meeting of the Association of Medical Men Receiving Resident Patients showed that the number of patients placed during 1908 was nearly double that in 1907, but the applications received from patients were not commensurate with the high demand for membership. The financial position, which rendered it possible to lower the subscriptions last year, continued, in spite of increased advertising and clerical expenses, satisfactory. Further particulars can be obtained from Dr. Hubert Biss, Honorary Secretary, 56, Outer Temple, Strand, London, W.C.

Obituary.

SIMEON SNELL, F.R.C.S. EDIN., D.Sc. SHEFFIELD,
HONORARY OPHTHALMIC SURGEON TO THE ROYAL INFIRMARY,
SHEFFIELD; PRESIDENT OF THE BRITISH MEDICAL
ASSOCIATION.

WITH profound grief we announce the death of Mr. Simeon Snell, President of the British Medical Association, which took place at his residence, Moor Lodge, Sheffield, on April 17th. For upwards of a year the state of his health had caused anxiety to his friends, and those who were present at the annual meeting in Sheffield will remember that he looked far from well, and was obliged to delegate to others some of the rather arduous duties that fall to the lot of a President.

Acting on the advice of his medical attendants he took a long holiday immediately after the close of the meeting, and on his return to work relinquished some of the less important of his numerous engagements. For a time he appeared to be more than holding his own, and it was hoped that he might eventually make a complete recovery, but a sudden change for the worse set in about two months ago, and after considerable suffering, which he bore with heroic patience, the end came peacefully while he slept. He died of arteriosclerosis and consequent heart failure. He was attended in his last illness by his friends, Dr. W. J. Martin, Dr. W. Dyson, Dr. Duncan Burgess, of Sheffield, and Dr. E. Colbeck of London.

Simeon Snell was born in October, 1851, near Launceston. He came of a medical family, his father, the late H. H. Snell, and several of his brothers being doctors. He was educated at Mannamead College, Plymouth, and pursued his medical studies at Leeds, Guy's Hospital, and Moorfields. He became M.R.C.S. in 1872, and L.R.C.P. Lond. in 1893, and subsequently took the diploma of F.R.C.S. Edin. He was an honorary D.Sc. of the Sheffield University, and for many years a J.P. for the City of Sheffield.

He settled in Sheffield in 1874, and soon afterwards was elected Honorary Ophthalmic Surgeon to the Sheffield Royal Infirmary, a post which he continued to hold until his death. He was Ophthalmic Surgeon to the Sheffield School for the Blind, and Consulting Ophthalmic Surgeon to the Moxborough Hospital. Throughout his entire medical career he was closely associated with the Sheffield Medical School. He took the warmest and most energetic interest in the project for establishing a university in Sheffield. His services in this matter were thus referred to by the *Sheffield Inde-*

pendent in the course of a sympathetic notice of his career:

It can be safely said that no one in the whole of the city entered with greater enthusiasm than did Mr. Simeon Snell into the obtaining of a charter for the Sheffield University. He was foremost at the numerous meetings which were held in the East End and other works in the city on many days of the week to enlist the sympathy and support of the workers of Sheffield in a cause which he felt was vital to the future educational and industrial progress of the city. Any waverers who were sceptical about the utility of a university in the way of furthering Sheffield's industrial position were soon converted by Mr. Snell's modest yet convincing arguments. He was an active and enthusiastic leader, and it is not possible to overestimate the value of the services he rendered in bringing the scheme to a successful conclusion.

When the university was constituted and when the

Sheffield Medical School was merged in it, Mr. Snell was appointed Professor of Ophthalmology, and allotted a seat on the council.

Mr. Snell's connexion with the Sheffield Royal Infirmary extended over a period of thirty-two years, and until his last illness he made a point of personally superintending the huge clinic which twice a week filled to overflowing the large out-patient rooms. In this way he had unrivalled opportunities of becoming practically acquainted with the accidents and diseases of the eye which arise among workmen engaged in the trades for which Sheffield is famous, and in the coal mines the proximity of which has been so great a factor in the prosperity of the city. These opportunities he turned to admirable account, and many of his numerous valuable contributions to the literature of the profession dealt with trade diseases and accidents, in

the study of which, as affecting the eye, he was a pioneer. Among his writings mention may be made of papers on the electro-magnet and its employment in ophthalmic surgery; miners' nystagmus; school life and eyesight; practical examination of the eye; prevention of eye accidents in certain trades; Report to the Home Office on alleged dangers from using masks and eyeguards in aerated water manufactories; acquired nystagmus from occupations other than coal mining; inquiry into the causes of blindness. The last paper, which was read at the Exeter meeting, resulted in the formation of a Special Committee of the British Medical Association for the purpose of considering the prevention of ophthalmia neonatorum.

He deservedly enjoyed a high reputation as an ophthalmic surgeon, and patients from a very wide area flocked to his consulting rooms. The appreciation of his work by his contemporaries secured for him many

distinctions. He was a former Vice-President of the Ophthalmological Society of the United Kingdom, Vice-President and, later, President of the Ophthalmological Section of the British Medical Association, President of the Yorkshire Branch of the British Medical Association, and of the Sheffield Medico-Chirurgical Society. A pupil of Wheelhouse, Clifford Allbutt, and Pridgin Teale, he remained their lifelong friend.

The crowning honour to a distinguished career came less than a year ago when, on the unanimous recommendation of his local compeers, he was elected President of the British Medical Association. On the recommendation of the Science Committee the Council of the British Medical Association performed the graceful act of conferring on its newly-elected President the Middlemore prize for his distinguished services to ophthalmology.

In earlier years he did much and excellent spade work, and there are few organizations in Sheffield that have not at one time or another experienced his effective help.

He was one of the hardest-working secretaries of the Sheffield Medico-Chirurgical Society, and on vacating this post to become President of the Society, his services were suitably acknowledged by the presentation of a massive piece of plate.

It was not in the practice of his profession alone that his great abilities and wonderful energy found outlets. He founded, and for many years was editor in chief of, the *Sheffield Medical Journal*. The success of this venture was so great that in a few years it was found necessary to broaden its title to that of the *Quarterly Medical Journal*. He wrote an interesting history of the medical societies of Sheffield, and was joint author of the history of the Sheffield Royal Infirmary.

For many years he took a leading part in the management of the Sheffield Literary and Philosophical Society, and with his co-secretary and intimate friend, the late Professor Clifton Sorby, F.R.S., raised it to the high position it now occupies among similar institutions. Ever ready to help a professional brother in distress, he was an active supporter of the West Riding Medical Charity. He was a devoted husband and father, and leaves a wife, two sons—one of whom has just entered the profession—and three daughters.

His remains were interred in Fulwood Churchyard on Wednesday, April 21st. The Right Rev. the Lord Bishop of Sheffield read the burial service, and the funeral was attended by a very large number of the members of the medical profession in Sheffield and the surrounding districts, by representatives of the Sheffield Royal Infirmary, the University, the Sheffield Medico-Chirurgical Society, the Sheffield Division of the British Medical

Association, the Literary and Philosophical Society, the Blind Institute, the Sheffield Book Society, and by a host of former friends and patients, and by Dr. J. A. Macdonald (Chairman of Representative Meetings), Dr. Rayner (Treasurer), by Drs. Goyder and Sinclair White, members of Council, and Dr. Turner, President of the Yorkshire Branch of the British Medical Association. The Chairman of Council, who was abroad, was represented by Mr. Gny Elliston.

The Bishop of Sheffield in his sermon on Sunday last at St. Mark's Church, where Mr. Snell was a regular attendant, made reference to the loss which Sheffield had sustained. There was missed, the Bishop said, that day from the great and growing city one who during the last quarter of the nineteenth century and the first decade of the present had done more than most men to help forward

the interests of Sheffield, and to make it famous amongst eminent and scientific men. During that period the progress and expansion of the city had been remarkable. Dr. Snell had taken his part in it, and he had been one of the makers of modern Sheffield. It was given to few men, the Bishop went on, to make their mark so early in life as did Dr. Snell, and still fewer to be able to add fame and renown to their reputation even to the very end. As one of the pioneers of the university he associated himself with the educational progress of the city. He was honoured last year by having conferred upon him the degree of a Doctor of Science, the highest distinction of its kind. Yet it was not by his honours that he would be remembered, but for his services to mankind.

Dr. HENRY DAVY, of Exeter, Mr. Snell's immediate predecessor in the office of President

of the British Medical Association, writes:

No one has had a better opportunity than myself during the past eighteen months of seeing the keen interest which our late President took in the British Medical Association. When, during last January, Mr. Snell went to Torquay for his health, he asked me to visit him there to talk over the affairs of the Association with him, and only last week, in a letter dictated to me from his bedroom, he said he hoped soon to be well enough to discuss business again. Mr. Snell had a very high sense of duty, and his first consideration as President was to try and act for the good of the Association, whether his action would bring him popularity or not. In all my intercourse with him I was struck by his painstaking thoroughness and the straightforward way in which he spoke out his thoughts. His ancestors came from Newton Ferrers, near Plymouth, and he was educated at Plymouth Grammar School. Although he had resided so long in Yorkshire, he remained a Devonian at heart. He

was always at home in his native county, and never was happier than when residing at his house at Teignmouth, which he occupied every summer. I feel that by the death of Mr. Snell during his year of office the Association has suffered a great loss. No one was a warmer or truer friend of the Association, or had its best interests more keenly at heart.

Sir ANDERSON CLITCHETT, Bart., writes: Ophthalmologists have recently had cause to realize with sadness that "the Angel of Death has been busy in our midst." It seems but yesterday that Argyll Robertson was taken from us; and now, after brief interval, he is followed into the silent land by his devoted friend and former pupil, Simeon Snell.

I shall always remember the latter as one of the most strenuous and conscientious workers in the profession. Had he been less prodigal of his boundless energy we might perhaps have been spared his untimely loss; but his faculties were ever at concert pitch, and he seemed to realize to the full Elizabeth Barrett Browning's terse and forcible injunction, "Get work; be sure 'tis better than that you work to get."

From the foundation of the Ophthalmological Society of the United Kingdom, Snell was one of its most loyal and consistent supporters. He contributed numerous valuable papers, and at his own expense he on many occasions brought interesting cases from Sheffield. Whenever there was an important question for discussion, he made the long journey from the North, arriving just in time for the meeting, and then, at its conclusion, rushing off to catch a midnight train. It is a matter for deep regret that the penalty for such consistent devotion to duty has been so heavily and so prematurely paid.

The summit of his professional career was reached when he was elected President of the British Medical Association, an honour which till then had never been achieved by any English ophthalmic surgeon, and he devoted his last store of energy to the duties of that high office, with the result that the meeting last year at Sheffield was one of the most successful on record. But the handwriting was already on the wall, and those who knew him best recognized with pain the gallant struggle of the indomitable spirit against rapidly failing powers.

Much of his work deserved, and will, I am convinced, obtain, permanent record; and as an instance of his thoroughness I may mention that at some personal risk he made many descents into coal mines whilst studying those special types of nystagmus concerning which he has written so well and so voluminously. He was probably without a rival in his experience of foreign bodies within the globe.

We can ill spare from our ranks one who possessed such high qualities of loyalty, integrity, and intellectual capacity, and Simeon Snell will ever be held in most kindly remembrance by all who had the good fortune to enjoy his friendship.

A colleague of Mr. Snell writes:

I desire to offer my tribute to the memory of a truly remarkable man.

His character may be summed up in the qualities of extraordinary energy, indomitable courage, transparent honesty of purpose, and a profound belief in himself. When Snell took anything in hand it was sure to succeed, if success was possible. An exceedingly busy man, unsparing of his energies, he got through an amount of work which to many would appear incredible. This was achieved by methodical habits, and by virtue of the faculty he possessed of doing most things outright at once. It is needless to say that such a character occasionally evoked opposition, but though a keen fighter he always fought with legitimate weapons, and in the open.

He was a man of many parts, and contrived to stamp his individuality on everything he did. As an ophthalmic surgeon he took high rank. A rapid yet profound observer, with a wealth of material at his disposal in the huge ophthalmic department of the Royal Infirmary, it was inevitable that he should come to the front in his speciality, and for many years he was the acknowledged leader in ophthalmology throughout a very wide area, while his contributions to the literature of his subject gained for him a world-wide reputation. He was espe-

cially brilliant as an operator, and I have been repeatedly told by competent observers of his work that they had rarely witnessed its equal. He instinctively appeared to know the right thing to do, and did it with a celerity and delicacy of touch which marked him as an artist in his speciality.

THE LATE MR. C. G. WHEELHOUSE.

DR. WARD COUSINS writes: Permit me to add a few words to the interesting biographical sketch of my old friend, Mr. C. G. Wheelhouse, which appeared in the last issue of the JOURNAL. Many years ago at the meetings of the Committee of Council I had the pleasure of meeting him, and I well remember his energy in promoting all the interests of the Association, and how greatly his help and co-operation were valued by all his colleagues. When the constitution in 1883 underwent reconstruction by the introduction of Branch representation he expressed some anxiety about the future of the Association, but in a very short time he recognized the importance of the changes which had taken place at the vital centre. Mr. Wheelhouse long occupied a distinguished position as a surgeon, and I desire especially to record my appreciation of the great improvements he introduced in perineal surgery which will always be associated with his name. He was the originator of a great advance in the treatment of severe and impassable urethral stricture. Until then external urethrotomy was generally performed without a staff, and it was regarded as an operation of extreme difficulty and danger. The important modification which Mr. Wheelhouse introduced is to-day known as the "Leeds operation." He published a full description of the method in the BRITISH MEDICAL JOURNAL of June 24th, 1876, and it was at once recognized as a great advance on the old haphazard operation. After putting in a straight guide up to the seat of the constriction, he explored the urethra by a free incision, and looking into the angle of the exposed and dilated passage, he passed through the constriction a director into the bladder, and then divided freely and often subcutaneously the whole length of the diseased tissues. By this simple and ingenious method the performance of an old, difficult, and dangerous operation was rendered at once both easy and successful, and to-day "a Wheelhouse" is practised in every hospital in the kingdom. I feel confident that all the members who enjoyed the advantage of knowing our old and much-esteemed friend will never forget his kind and genial presence, and all his invaluable services in the development and progress of the Association.

CHARLES BELL TAYLOR, M.D. AND F.R.C.S. EDIN.

We have received through the Chairman of the Nottingham Division of the British Medical Association the following tribute from a friend to the late Dr. C. B. Taylor, of Nottingham, who died on April 14th, in his 80th year:

"Charles Bell Taylor was born at Nottingham, where his father and brothers were well-known veterinary surgeons; and to Nottingham came patients to consult him from all parts of the world to the end of his long career. He was a masterly operator, but it may be doubted whether it was mainly to this that he owed his fame. It was his personality which drew and held his patients. No one who had seen him would readily forget him. Tall and dark and commanding, his piercing black eyes looked out under his deep brows with an expression of peculiar intensity. Some of his patients were afraid of him, far more were attracted, and all were dominated by him.

"He was a great individualist, and all that interfered with the liberty of the individual met with his uncompromising and eloquent denunciation; and the opponents of compulsory vaccination, of the Contagious Diseases Acts, and of vivisection, found him a powerful ally on their platforms. Beyond this he took little part in public affairs, his own special work providing full occupation for the energies of an unusually vigorous mind.

"The amount of work he did was enormous. For many years, in addition to his private practice, he did a large proportion of the work of the Nottingham and Midland Eye Infirmary. He never had a qualified assistant; even the services of a trained nurse appeared to him a boon of

doubtful value. Until his last brief illness (influenza) he was never, even for a day, deterred by ill health from seeing his patients. Probably his abstemious mode of living combined with his great vitality to produce this result: he never had more than two meals a day, and he abstained altogether from alcohol, tobacco, and even from tea and coffee. Certainly it is given to few men to perform, as he did, at 80 years of age, the most exacting operations, with a hand as steady as in his prime.

"Perhaps the characteristic of his operating which struck one most was his entire imperturbability; the eyeball seemed as if it were clay in his hands, to be moulded at his will. He always operated by artificial light, and a striking picture might have been made of the curtained room, with its single lamp, its rays concentrated on the face of the patient by an enormous globe of water, giving something of the air of an alchemist's chamber to the scene, while above the patient's head loomed the strongly-cut features of the operator, and among the shadows flitted William, the attendant, with the instruments; and further back, perhaps, was a suggestion of the hushed figures of the patient's friends.

"His favourite operation was that for cataract, which he did, whenever it was possible, without an iridectomy, placing his rather large incision exactly in the corneoscleral junction, and delighting with the delight of an artist—in his work in the result of 'an operation without a scar.'

"In his choice of anesthetics, he was, as in many other things, peculiar; for, though educated at Edinburgh in the days of Simpson, he held chloroform in abhorrence, and used to rapidly smother his patients with ether vapour almost undiluted with air, and it is believed he never had a mishap. The writer has seen him extract a cataract without any anaesthetic, local or general, and without the flicker of a muscle on the part of operator or patient—a striking testimony to the magnetic influence of his personality.

"It is a truism to say that the surgeon must have confidence in himself before he can communicate it to his patients, and this Bell Taylor possessed in a supreme degree. It was said that the expression 'I can't' did not occur in his vocabulary.

"His great skill was as freely given to the poor as to the rich, and beneath all the peculiarities of the man was a nature of real simplicity and kindness."

HENRY STILWELL, M.D.

AFTER a short illness, Dr. Henry Stilwell, late of Moorcroft, Hillingdon, died, aged 73, on April 12th, at Eastbourne, where he had lived since his retirement in 1906.

After leaving Rugby School, he entered St. Bartholomew's Hospital in October, 1853, and, after spending a year at Edinburgh, obtained the degree of M.D. Edin. and the diplomas of M.R.C.S. and L.S.A., in 1857. After a visit to Australia, he assisted his father, the late Mr. James Stilwell, F.R.C.S., in general practice at Uxbridge for two years. He was then called upon to join his cousin in the management of the asylum in that district. For upwards of forty-five years he held the position of Medical Superintendent at Moorcroft, Hillingdon.

He was an old member of the British Medical and Medico-Psychological Associations, and until recently was a frequent attendant at their meetings. For many years he was the local Secretary of the Epsom Benevolent Fund. In his social as well as professional spheres Dr. Stilwell was always held in high esteem, being regarded by every one as a man of the strictest integrity. In his asylum life he was a successful organizer, and was much liked by his patients, to whom he gave much of his time and personal attention.

As an alienist his opinion was sound, although cautious as to prognosis. A man of many parts and fond of reading, he did not neglect to preach and practise the doctrine of physical exercise and outdoor life. In bygone years his chief recreation was hunting, and he was regarded as a good judge of a horse. Latterly he had taken to golf. He was well known as a member of the Edinburgh University Club, and he attended regularly the dejeuner dinners of St. Bartholomew's Hospital. Dr. Stilwell leaves his wife, son, and three daughters to mourn his loss. The funeral,

which was held at Hillingdon on April 16th, was attended by his son, sons-in-law, and many sorrowing friends.

WILLIAM GABRIEL ROCKWOOD.

CONSULTING SURGEON TO THE COLOMBO GENERAL HOSPITAL.

NEWS has been received of the death, on March 29th, of Dr. W. G. Rockwood, a Cingalese practitioner of much distinction, and one well known to many of his colleagues in this country. Dr. Rockwood, who was a Tamil by birth, was born in Jaffna, Ceylon, in 1843, his father being a Subcollector of Customs. He received his general education partly in Ceylon and partly at the Presidency College, Madras. At the latter institution he gained a scholarship, and passing on to the Madras Medical College in 1861 received the licence of the College after a five years' course. At a later date he obtained the degree of M.D. of the University of Madras; and still later was admitted to the Membership of the Royal College of Surgeons in England. Meantime he had returned to his native country, and obtained appointment in the medical department. He proved from the first a most excellent officer, his professional work attracting so much favourable attention that on the death of Dr. Koch he was appointed Surgeon-in-Charge of the General Hospital, Colombo, and the Lying-in Home. This appointment carried with it that of Lecturer on Surgery and Midwifery at the Ceylon Medical College, which he held for many years, finally retiring from Government service under the age limit in 1898. His professional services were then recognized by the creation of the post of Consulting Surgeon to the hospital and his appointment thereto, and a little later he was selected by the Governor to represent the Tamil community in the Legislative Council. It was a happy choice, for he brought the same industry and intelligence into play in his new duties as he had previously exhibited in professional connexions, and on the termination of his five years' period of office he was reappointed for a like term. Not long after this event his health unfortunately showed evidence of failure, and finally in 1906 an attack of paralysis led to his giving up both professional and political work altogether. During his active life Dr. Rockwood contrived to find plenty of time for social and professional intercourse, and took a keen interest in the affairs of the British Medical Association. At one time he was President of the Ceylon Branch, and on several occasions came to England to attend the Annual Meetings. His last visit was in 1902, when he attended the Meeting at Manchester as a delegate of the Ceylon Branch. His ability, industry, and sound judgement gained him a well justified reputation, and made him so useful a member of the community in Ceylon, that, despite the fact that he appeared rarely in public after his retirement, his services were not forgotten. Widespread regret was aroused by the news of his death, and was expressed on behalf of the Government by a telegram from Sir H. E. McCallum to his family, and by the attendance at his funeral of representatives of all sections of society. Dr. Rockwood was married, and is survived by several daughters and sons, two of the latter being medical men.

WE regret to record the death on April 5th of Dr. EDMUND WEARE CLARKE, of Chesterfield. He had been resident in Chesterfield for many years, and for long was so prominent a figure that his death at a comparatively early age leaves a much-regretted blank. It was due to heart failure and occurred quite unexpectedly. Dr. Clarke was a Cornishman by birth, but received his education in Edinburgh, which he left in 1885, after a student career of considerable distinction. During its course he devoted much more time to pure science than is common among medical students, and was rewarded for his pains by the B.Sc. Edin., as well as by the M.B., C.M. Edin. A year later he became M.R.C.S. Eng., and then went abroad to continue his medical studies, partly in Paris, partly in Germany. Finally, he presented himself for the M.D. of his old university, devoting his thesis to appendicitis, a comparatively new subject at that date. In Chesterfield he settled down some seventeen or eighteen years ago as successor to the late Dr. MacDonnell, whose practice he materially increased. Of late years, however, he had restricted his professional energies, and devoted a great

deal of his time to literary occupations. In addition to his knowledge of modern languages he was a good classical scholar, and at the time of his death was engaged in the compilation of metrical translations of some of the Greek and Latin writers whom he more specially favoured. Another matter in which he took special interest was first-aid work. As a lecturer to the local branch of the St. John Ambulance Association he was particularly successful, and his work for the corps had recently been recognized by his appointment as an examiner to the central body. He was also a member of the Royal Physical Society of Edinburgh, and for a good many years took an active part in the proceedings of the Sheffield Medico-Chirurgical Society, of which he was at one time President. Dr. Clarke was married, and is survived by his wife, the youngest daughter of Mr. Bowery Douglas.

DR. THOMAS CRAWFORD HAYES died on Monday, April 5th, at his residence in Clarges Street, W., after a long illness. He was the son of Frederick William Hayes, a mill-owner in county Down, and was born at Seapattrick, Banbridge, on October 18th, 1843, the youngest of nine children. His father died when he was 9 years old. At the age of 7 he was sent to Dr. Forrester's school in the Isle of Man, and was afterwards instructed by a private tutor until he returned to Ireland. He originally intended to enter the Church, but after becoming a student at Trinity College, Dublin, he found that he felt more fitted for the cure of bodies, and during his college career he spent much time in coaching younger and more backward fellow students. Precocious as a child at school he proved brilliant as a student at Trinity. He became a Senior Moderator and Gold Medallist at Trinity College; afterwards he studied at King's College, London, and became House-Physician to the hospital. He obtained the diploma of L.S.A. in 1870, that of M.R.C.P. in 1872, and graduated M.B.Dub. in 1873; he graduated M.D. in 1875, and was elected F.R.C.P. in 1889. In 1872 he was appointed Assistant Physician for Diseases of Women and Children, and Assistant Accoucher to King's College Hospital, and seven years later succeeded to the appointment of Physician for Diseases of Children, and Physician Accoucher to in-patients and out-patients; Dr. Playfair, holding a similar appointment, reckoned as senior. In 1893 Dr. Hayes became Physician Accoucher, the title given to the senior appointment, Drs. Playfair, Hayes, and J. Phillips working together at the hospital for several years. Dr. Hayes also held corresponding teaching appointments at King's College, beginning as Lecturer on Practical Obstetrics in 1889. He was appointed Professor on Practical Obstetrics in 1896, and Professor of Obstetric Medicine and Diseases of Women and Children in 1898. On his retirement in 1906, Dr. Hayes was made Consulting Physician to the hospital, and Emeritus Professor to the College. He was also on the medical staff of the Royal Free and other hospitals, and was for a time Examiner in Midwifery and Diseases of Women on the Conjoint Board. Dr. Hayes wrote little; he was, however, an active Fellow of the Obstetrical Society of London in the Eighties, exhibiting many specimens and reading clinical reports of considerable interest.

We regret to have to record the death of Mr. THOMAS WILLIAM NUNN, Consulting Surgeon to the Middlesex Hospital, which took place at his country residence, near Royston, on April 13th, after a very short illness. He was 84 years of age, and until within the last few years was a familiar figure in London. Several generations of students of the Middlesex Hospital will have pleasant recollections of him, as he was on the active staff from 1846 to 1879, when he was appointed Consulting Surgeon. Mr. Nunn received his medical education at King's College, of which he was a Medical Associate, and where for a time he assisted in teaching anatomy. In 1846, however, he was appointed Demonstrator of Anatomy at the Middlesex Hospital, to which institution he remained attached, and where he was often to be found for the rest of his life. He was appointed Assistant Surgeon in 1858, Surgeon in 1863, and Consulting Surgeon in 1879. He taught anatomy for sixteen years, and gave it up, much to the regret of his pupils, to teach practical and operative surgery, which he continued to do till 1873. He served for a time as a combatant officer in the Militia, but after a few years changed

this for a medical commission, and joined the West Middlesex Rifle Volunteers, from which he retired as Surgeon-Major after over twenty years' service, receiving the Volunteer Decoration. His chief publications were on the subject of cancer, particularly as to its treatment, but he also contributed papers on various subjects to the medical journals and the Clinical and Pathological Societies; of the latter he had been a Vice-President. He was twice married, and leaves a widow but no family. His funeral took place on April 19th in Royston Cemetery, and was attended by some of his old colleagues and pupils.

ON March 30th there passed away, in the person of GEORGE PERCIVAL HADLEY, of Lozells Road, Birmingham, a well known and highly respected practitioner of medicine. He was born in 1845, the son of John Joseph Hadley, who was for many years a general practitioner in Birmingham. He was educated at King Edward School, Birmingham, from whence he passed the matriculation of the London University. He commenced his medical education at Sydenham College and the General Hospital, Birmingham, and obtained the M.R.C.S. in 1867, and the L.S.A. in 1868. Afterwards he proceeded to the Queen's College, Belfast, where he obtained the M.D. in 1868. Shortly after this he purchased a practice in the Lozells district of Birmingham, and continued to practise there until a few years ago, when the condition of his health compelled him to retire. In his early life he was for some years a Surgeon in the Birmingham Rifle Corps, and shortly after settling in the Lozells became a member of the Aston Manor Local Board; he was one of the first members of the Free Libraries Committee, and took a deep interest in the work connected with that institution. As his practice grew Dr. Hadley was compelled to relinquish these public offices, but he continued to take a great interest in the work of the Established Church, of which he was an ardent member. He did much for his parish church (St. Paul's, Lozells), being first a member of the Building Committee, then for many years Vicar's Warden and Treasurer of the Home Mission Fund. He was a member of the British Medical Association and the Midland Medical Society, and one of the oldest subscribers to the Birmingham Benevolent Society. He was twice married, and leaves by his first wife a family of three sons and five daughters. One of his sons is following his father's profession, and is a graduate of the Birmingham University. His second wife survives him. Such is a short account of a man who was a firm friend and a conscientious adviser in all matters connected with his profession. His retirement was much regretted by his former patients, and he will now be greatly missed by his personal friends.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Theodor von Dunin, Physician to the Hospital of the Child Jesus in Warsaw; Dr. J. P. Barette, Professor of Clinical Surgery at the Medical School of Caen, aged 54; Dr. von Mangoldt, a leading surgeon of Dresden, where he had charge of the surgical department of the Olga Hospital, aged 50; Dr. N. S. Speransky, Lecturer on Dermatology and Syphilography in the University of Moscow; Dr. Phineas S. Conner, for forty years Professor of Surgery in the Medical College of Ohio, aged 80; Dr. Robert Raeburn of Washington, one of the surgeons who attended President Garfield on his deathbed, and was for some years Dean and Professor of Hygiene and Preventive Medicine in Howard University, aged 75; Dr. W. F. Wokressenski, Professor of Operative Surgery and Topographical Anatomy in the University of Charkoff; Dr. Theodor Haase, Member of the Austrian House of Lords, and a well-known sanitarian and promoter of the building of hospitals, aged 74; and Dr. E. Kufferath, Professor of Obstetrics in the University of Brussels.

TUNBRIDGE WELLS lost in March a much-valued inhabitant in the person of Dr. JAMES EISSHOPP, of Mount Pleasant. He was a cadet of a very old Sussex family, and received his medical education partly at St. George's Hospital, partly at Guy's. Entering the latter in 1846, he was a member of the Guyite Club, and at the date of its dissolution a year or two ago was one

of its only three survivors. There are now only two, Mr. Thomas Bryant, Consulting Surgeon of the hospital, and Dr. Samuel Knaggs, of Huddersfield. In Tunbridge Wells Dr. Bisshopp established himself in practice some forty years ago, and he had only given up work within the last ten years. He was over 86 when he died, but his work was not forgotten, and being a man of singularly cheerful, friendly nature, and until lately in comparatively good health, he continued to play a pleasant part in the life of the locality in spite of advancing age.

Correspondence.

THE PREPARATION OF CATGUT FOR SURGICAL PURPOSES.

SIR,—The interesting and suggestive paper in the JOURNAL of April 17th by Mr. W. G. Richardson on Tetanus after Operations, with the query, Is the infection introduced by catgut ligatures? and the able leading article in the same number, will, it is hoped, elicit further information on the mysterious "tetanus" side of this important question, to which I shall not further allude.

My object is to ask on the part of surgeons a more general and thorough appreciation of Lister's (1) perfected method of preparing catgut and (2) method of sterilizing skin and instruments before operation.

1. The method of catgut preparation is referred to in the editorial article to which I allude. It relates to the "green catgut," prepared by soaking twenty-four hours in sulphate of chromium, and was made known to manufacturers in 1894, but never published until January 18th, 1908, in this JOURNAL by Lord Lister himself. That brief account I venture to call a complete description of the simplest, quickest, and most durable form for all purposes, with perfect tests of its efficiency added.

I note that Mr. Richardson had some of his catgut soaked in ether, then placed in mercury biniodide dissolved in 1,000 parts of methylated spirit, other portions being boiled for an hour in absolute alcohol. Without disparaging these and other different methods of more or less efficiently "tanning" catgut for surgical purposes, and without prejudice to Mr. Richardson's modest and candid statement of his experiences, I now suggest that it can hardly be further advisable to depart from the methods, conclusions, and preference expressed by the author of antiseptic surgery. Those surgeons who, like myself, have from time to time for years blindly relied on this form of catgut, as issued in dry hanks from the shops, and made ready for use by steeping for a quarter of an hour in 5 per cent. carbolic lotion, have found it in every respect satisfactory. But among the many pitfalls of antiseptic practice, especially when complicated by great variations in ritual, catguts of various make have sometimes been accorded a bad name, and surgeons have resorted to their own methods of preparation, often excellent, in preference to risking that of the shops, for want of knowing that the green variety has all along been that of Lister. Even the publication on January 18th, 1908, must, if even only for a time, have been overlooked by some, as it actually was by myself.

2. On June 27th, 1908, Lord Lister published also in this JOURNAL Remarks on Some Points in the History of Antiseptic Surgery, constituting a wonderful epitome of the aims and methods of his antiseptic practice, in a space of less than two pages. In this is stated his invariable practice during forty years of relying on 1 in 20 carbolic solution in water for sterilizing the hands and instruments of the operator, and the skin of the patient, without previously removing the grease from the latter, or wetting the epidermis, much less scrubbing with soap and water. In this paper he says:

I cannot but think it a happy circumstance that this substance, which I employed first in endeavouring to apply the antiseptic principle, should have been so admirably adapted for detergent purposes. And it has grieved me to learn that many surgeons have been led to substitute needlessly protracted and complicated measures for means so simple and efficient. The fear sometimes expressed of poisonous effects from carbolic acid, as used in antiseptic surgery, is, so far as my experience goes, entirely groundless.

Probably the brief duration of Lister's exposure of the skin to carbolic lotion before operation protected his

patients from the poisonous symptoms that others have occasionally met with.

If these two brief papers, from one of the first and from the last number in this JOURNAL of vol. i, 1908, were mounted and hung up in every hospital and medical school for repeated study by all engaged in surgery, they would serve an invaluable purpose by spreading and simplifying antiseptic precautions among all concerned, and not least among those who are chiefly likely to encounter "minor" cases, for, when these "go wrong," much "major surgery" may result.

I well remember the interest aroused by the appearance in 1867 of Lister's communications "on a new method of treating compound fracture, abscess, etc.," and the excitement produced in myself and fellow-students and house-surgeons at University College and Hospital in 1868 and 1869 by the publication of his early "ligature of arteries on the antiseptic system," first by carbolized silk and then by carbolized catgut. To many it must be a welcome announcement, made in this JOURNAL on April 10th, 1909, that Lister's collected papers and addresses are shortly to be published in two volumes by the Clarendon Press.—I am, etc.,

ALLAN RUSHTON PARKER,
Professor of Surgery in the University of Liverpool.

HUNGER PAIN AND DUODENAL ULCER.

SIR,—Mr. Mansell Moullin has stated the surgical opinion concerning hunger pain with perfect clearness. Of the cause of this pain I am not sure that we know the correct explanation, and all that I am prepared now to admit is that the time of the onset of pain corresponds to the time at which the food begins to come in contact with the ulcer. And a similar statement may be made about the "prepyloric" ulcers on the lesser curvature, whose exact position can often be predicted before operation. I should be interested to hear if Mr. Mansell Moullin has considered the possibility of the peritoneum being the sensory surface; especially in view of recent work. The duodenal ulcer which has caused attacks of "hunger pain" has always reached the serous coat. The phenomenon of pylorospasm has, I am sure, symptoms different from "hunger pain." I think I know them now sufficiently well to be able to say in many cases that the lesion will be not in the duodenum, but elsewhere, and to forecast its nature and position. But I will presently return to this point after I have dealt with the fallacies of Dr. Hertz.

Dr. Hertz is troubled at my disbelief in *post-mortem* statistics, and, in wonder, asks me if I believe "that the bodies of people with duodenal ulcer go straight to another world without passing through the *post-mortem* room." Most certainly I do believe this of the vast majority. Does any one doubt it? Does Dr. Hertz suppose that anything more than a very insignificant proportion of bodies pass through the *post-mortem* room? The patients admitted to hospital are a very small fraction of the total number of sick people. Of patients so admitted about 5 per cent. (let us say) die. Not all the bodies of those who die are submitted to *post-mortem* examination. Of the bodies so examined, a lesion not immediately concerned in the death of the patient may well be overlooked, no matter where or by whom the inspection is made. Yet inferences drawn from these probably imperfect records of a very small, and in no sense representative, proportion of the total deaths are considered to have a strict numerical application to the diseases of the living. When the surgeons speak of the frequency and of the clinical features of duodenal ulcer or cholelithiasis, or pancreatitis, or of common duct obstruction, or of many other conditions, we are supposed to be answered, and to have our experience and conclusions tested and refuted, by a reference to the imperfect records made in the ancient days when little or nothing was known of these various diseases. It is worth while, then, to follow Dr. Hertz in his digression to shatter the idol which he and others have worshipped with such ecstasy. It is a poor dead doll.

I showed in my last letter that Dr. Hertz confused the relief of an "attack" in a patient suffering from duodenal ulcer with the cure of the disorder, and that he omitted to take note of recurrences. But, I am told in reply (a variant of the eternal *tu quoque*), recurrence also takes place after surgical measures have been practised. What is the evidence Dr. Hertz gives of this? It is that he has been

consulted by three patients for the return of symptoms after repeated operations undertaken for the relief of "supposed gall stones or gastric ulcer." The argument is that since in these three cases repeated operations whose nature is not mentioned were undertaken for symptoms whose origin was never determined, the conclusion must be drawn that the treatment of duodenal ulcer by operation is followed by recurrence. Is it necessary to answer that? Refutation of that kind of logic is too easy to be amusing. Dr. Hertz as a disputant delights me; but I could not persuade myself again to take him seriously.

Dr. Irwin's letter is a valuable record of a personal experience. The description of the second, or "ulcerative," stage in his history is, I think, that which corresponds to the "hyperchlorhydria" of Dr. Hutchison and others. My point is that recurrent "hyperchlorhydria" is duodenal ulcer; when I operate upon the patients who bring this diagnosis with them, I find they have duodenal ulcer. Hyperchlorhydria at first was used as a term descriptive of a chemical condition; it is now debased, and is given a clinical significance. To the description of their pain given to me by patients who were shown to have duodenal ulcer I attached the term "hunger pain." Dr. Hertz and Dr. Hutchison speak of the "extreme frequency" of this symptom. I suspect that they are including under this term some, at least, of those conditions in which "acidity" (occasional or persistent) is described by the patient. In these cases the apparently increased acidity of the stomach contents is probably to be explained in this way. A lesion exists beyond the pylorus; it may be in the gall bladder; it may be a tuberculous ulceration in the intestine, an inflamed appendix, etc. It may be, that is to say, in any of the derivatives of the mid-gut. The irritation of this lesion excites a pylorospasm, which, when the abdomen is opened, may quite plainly be seen. The spasm is probably protective; the lesion in the gut desires to be shielded from the harm caused by the passing food. As a result of this spasm the food in the stomach finds a difficulty in getting through the pylorus. The demand of the food for admission to the duodenum is usually made by the excitation of an acid reflex. As the demand receives no response, it is perhaps made more imperative by an increase in the acidity, or relief may be obtained by the belching-up of bitter fluids or of gas. This is a pretty story, truly; but the work of Pawlow, Starling, and Cannon shows that every detail in it is corroborated by experimental evidence, and the clinical evidence, which is interesting, I may some day lay before you.

"Hunger pain," as I have described it in all its attributes, is the symptom on which a diagnosis of duodenal ulcer will be proved by operation to be correct in almost every case. The mimicry of it in the conditions I have just referred to may be close; but when the abdomen is opened, gastro-enterostomy must on no account be undertaken unless the lesion is plainly to be seen by any onlooker. This discussion will have borne good fruit if only it sounds the death knell of "symptomatic" gastro-enterostomy.—I am, etc.,

Leeds, April 19th.

B. G. A. MOYNIHAN.

SIR.—Dr. Hutchison, in his letter of March 20th, gives very definite information upon the possible antecedents of duodenal ulcer. He states that recurring attacks of dyspepsia characterized by "hunger pain" mean hyperchlorhydria; when the attacks become more frequent and finally constant they denote continuous hypersecretion. This is delightfully simple, and we naturally look for equally definite directions from him of the presence of a duodenal ulcer, but in vain. He says, "in a certain number of cases unmistakable signs of duodenal ulcer appear, and the case passes into the hands of a surgeon." It is disappointing that he does not tell us what these unmistakable signs are. It is presumed by them are meant melæna or hæmatemesis, or both, accompanied by the tender spot beneath a rigid right upper rectus, possibly the presence of a palpable tumour, or, finally, the signs of perforation. The last named are unmistakable enough, but what of the others? Rather, of what value is their absence? The last three cases of perforated duodenal ulcer on which I have operated (all of them within the last nine months) supply the answer. I quote them not in the least by way of criticism of the

diagnostic skill or care of their medical attendants, but to emphasize the fact that our surgical acquaintance with the abdomen of recent years must compel us, in many instances, to place a different interpretation on symptoms and signs which have hitherto been associated with such terms as "acid dyspepsia," "atonic dilatation," etc.

None of these patients had ever suffered from naked-eye hæmatemesis, or, to their knowledge, from melæna. In none of them was a palpable tumour present, although all of them were found at operation to have very large and evidently very chronic ulcers; they had all been examined and treated for years by more than one physician, and in none of them had the diagnosis of duodenal ulcer been made; one of them, a few months previous to perforation, who had been a chronic sufferer for many years, had been examined by a London physician attached to one of our largest teaching schools, and had had the definite opinion from him that he was suffering from atonic dilatation of the stomach and had no ulcer. Yet, till he perforated a few months afterwards, there was no change in his symptoms. After recovery by operation from their critical conditions all of these patients gave the history of acid dyspepsia extending over many years, and all of them had been "cured" many times. In two of them "hunger pain" had been prominent; in the third it had not. None of them up to the time of perforation had had any "unmistakable" signs of duodenal ulcer other than these. My experience does not enable me to say that every case of acid dyspepsia accompanied by "hunger pain" means duodenal ulcer, but certainly suggests that when such symptoms persist (especially in men), are rebellious to treatment, or constantly recur, they should excite the suspicion of something more than a functional dyspepsia, a suspicion that, when the abdomen is opened, will usually be ascertained to have been well founded. It should be borne in mind that perforation is no more the time of election for the cure of a gastric or duodenal ulcer than is strangulation the time of election for a radical cure of hernia. With the progress of knowledge of diseases of the gall bladder and its ducts, of the appendix, stomach, duodenum, pancreas, etc., it seems that those often vague complaints "indigestion" and "liver" are gradually but surely being elbowed out of the field. In 80 cases of operation for gastric or duodenal ulcer my margin of error has been 5 or 6 per cent; in other words, in 6 per cent. of cases (all of them women) I have opened the abdomen expecting to find an ulcer, and have found none. Not one of these patients was the worse for the simple operation, and in fact the physicians attending them were by it placed in a far stronger and more confident position as regards their future treatment, so that in reality out of evil good came, and the clearing up of some of these cases, even at the expense of an unnecessary exploration, is not always without its advantages. However that may be, I maintain that it is better to make such a mistake occasionally than by medical treatment to go on relieving, as I have repeatedly seen, conditions which subsequent operation demonstrates conclusively were incapable of cure except by surgical means, or to diagnose a gastric or duodenal ulcer after it has perforated. I have at the present moment in hospital a patient who has been "cured" no less than six times during the last six years. I operated upon him on April 12th, and found a chronic indurated pyloric ulcer the size of a pigeon's egg, with numerous perigastric adhesions. I have not the least doubt, from an experience of many similar cases, that gastro-enterostomy will at last cure him—better late than never.—I am, etc.,

Portsmouth, April 19th.

CHARLES P. CHILDE.

ANAPHYLAXIS: A PROTEST IN NOMENCLATURE.

SIR.—The more advanced a science becomes, the more exact should be the use of its terms. Few impediments to the gain of real knowledge of fact thwart our efforts to such a degree as unmeaning words; and such phrases as "dry subceptant riles," "hypersthenic dyspepsia," and many others, positively handicap progress; we may each have a type of condition in our minds, but there is little to guide different members in associating the same term with the same phenomenon. A new language of medicine is being built up, and the necessity of accuracy and lucidity is clear.

"Anaphylaxis" is a term lately introduced to designate the increased susceptibility to serum after the first dose when introduced under the skin or into the peritoneal cavity. If an animal receive a dose of serum, after a latent period of ten days or so certain symptoms develop. If in the next few weeks the exact same dose is repeated, then there is much shortening of the latent period, even to minutes, and, to use the eloquent phrase of Professor Symmers, "there is an acceleration of symptoms which run a tempestuous course." This is called anaphylaxis.

The word recalls to us at once the term "prophylaxis." If diphtheria threaten in a household, we give to the untouched members a dose of diphtheria antitoxin (that is, horse serum plus diphtheria antitoxin); this is as a prophylaxis. Now, if in a few weeks we repeat the same dose of the antitoxin, there does not appear to be any "anaphylaxis" as regards diphtheria—indeed, probably there is increased "prophylaxis"—but there is "anaphylaxis" as regards horse serum, which in the human subject shows itself as a shortened latent period, oedema (chiefly of face), erythematous and urticarial rashes, and fever.

We have causes of "anaphylaxis" as regards specific diseases, such as starvation, exhaustion, exposure to cold, anaemia, to mention the most evident; it is, I think, yet to be ascertained whether the same conditions induce anaphylaxis as regards serum. On the other hand, it is said that the "serous diathesis" is a condition of anaphylaxis as regards serum; whether it holds also as regards one or any or all specific affections has practically not been entertained.

I would venture to suggest that before this new term becomes stereotyped by prolonged use it should be dropped in the somewhat vague sense in which it is used, or that some adjectival word or phrase be added to show what is meant. If "serum susceptibility" be of the same nature as diminished immunity to specific poisons, then we may very well use such phrases as "serum anaphylaxis," "diphtheria anaphylaxis," but then we cannot clearly understand how "diphtheria prophylaxis" gained by the use of the ordinary commercial antitoxin, when repeated in a few weeks, involves "serum anaphylaxis," but does not involve "diphtheria anaphylaxis." The experience from typhoid and vaccine inoculations in general is against the supposition that the two susceptibilities are the same in kind, but differ in degree. It seems thus rather a retrograde inexactness of language to use "prophylaxis" for one condition, and "anaphylaxis" for the other.

A recent admirably lucid and suggestive lecture by Professor Symmers on anaphylaxis has prompted this protest.—I am, etc.,

Belfast, April 2nd.

W. CALWELL.

INDIAN MILITARY INVALIDING.

SIR,—In the JOURNAL of March 6th some extracts from Mr. Haldane's statement on the Army Estimates and ratios per 1,000 from 1888 to 1907 of invalids sent home from India are quoted. For the last two of these years you give the figures respectively as 28.37 and 25.47 on an average strength of 67,406, and, comparing them with preceding years, you deduce much cause for congratulation on increased medical efficiency. Had you known the very latest figures, you could have multiplied that congratulation tenfold, and so could Mr. Haldane.

Let me explain that the invaliding season extends from October to March, so that to arrive at an estimate it is better to compare seasons than years. On this basis, then, and on the average strength given, the figures are:

1906-7	31.21
1907-8	15.8
1908-9	13.21

The actual number of invalids sent home in these three seasons was 2,105, 1,071, and 891 respectively. The strength, approximately, was some 3,000 higher than you put it, so that the ratios are even better than those quoted.

It would occupy too much of your space to explain the phenomenal decrease in the last two seasons. You will observe that we have saved rather more than a battalion in each year, and I venture to predict that in the future,

and under normal conditions, the Indian invaliding will not rise above 15 per 1,000.—I am, etc.,

Bombay, March 25th. Colonel, P.M.O. Bo, Brigade.

RURAL DISTRICT NURSING ASSOCIATIONS.

SIR,—I have read the correspondence re district nurses with much interest, and think that a pamphlet entitled *A Day in the Country with a Queen's Jubilee Nurse*, issued presumably with the authority of the Queen Victoria's Jubilee Nursing Institute, fully bears out the statements of your various correspondents who have experienced the drawbacks of the system.

To those who are dissatisfied with that system may I suggest that they should endeavour to form branches of the Cottage Benefit Nursing Association, formerly known as the Holt-Ockley system? To such of them as are unacquainted with this association I may briefly say that the point of the system is that a nurse takes care of only one case at a time, residing in the house and attending to the various duties that arise in the household as well as nursing the patient, and this, I think, is of greater advantage to both doctor and patient than the butterfly visits of the district nurse. The nurses are drawn chiefly from the cottager class, trained long enough, in a special manner among the poor, to enable them to note symptoms carefully and carry out the directions of the doctor intelligently, whilst not long enough to lead them to think themselves competent to go beyond the whole duty of a nurse, and take the place of the doctor. By the central rules of the Cottage Benefit Nursing Association every branch must have at least one doctor on its committee, and the nurses must work under the orders of the doctor whose case they are nursing. I enclose a copy of the rules of a branch that has lately been formed here, which are in every essential similar to those of a large branch in the Midlands, whose rapid growth and striking success are, I believe, attributable to the policy of hearty co-operation with the doctors of the district, pursued by the secretary from its foundation fourteen years ago. At first only one doctor approved of it, but now all in the neighbourhood avail themselves of the services of its nurses when they can get them, and other branches have been and continue to be formed around it. I have personally had many of its nurses working under me, and have found them thoroughly useful, and quite competent for most medical and surgical cases.—I am, etc.,

Stradbroke, Eye, April 13th.

J. A. BALL, M.B. Lond.

STRADBROKE BENEFIT NURSING ASSOCIATION,

For providing Nurses for the Sick in Country Parishes.

RULES FOR PERSONS REQUIRING A NURSE.

Price One Penny.

1.—Applications for Nurses must be made to the Committee Lady, to be transmitted by her to the Secretary. No Nurse can attend a case without an order from the Secretary or in case of emergency from the Committee Lady.

2.—Subscriptions and fees must be paid to the Committee Lady. If a subscription is in arrear the patient will be charged non-subscribers' fees. Board and Lodging for the Nurse must be provided by the patients or their family. The following is the scale of payment:—

	Yearly.	Fees per Week.
Class 1	...	2s.
Class 2	...	3s.
Class 3	...	5s.
Class 4	...	7s. 6d.
Class 5	...	10s.

3.—A double charge will be made for infectious cases to meet the cost of disinfection; also when a case has lasted six weeks.

4.—Non-subscribers may have a Nurse, if one can be spared, on condition that she leaves if the Secretary requires her. Class 1, 5s.; Class 2, 7s. 6d.; Class 3, 12s. 6d.; Class 4, 17s. 6d.; Class 5, 25s.

5.—No person will be allowed to join the Association when ill.

6.—Notice of not less than two months must be given by Subscribers when engaging a Nurse for a confinement. For Classes 1 and 2 the fee will be charged from the day the Nurse goes to the house; for the other classes will be charged from the date for which the Nurse was engaged. In maternity cases no Nurse will be allowed to attend unless a Doctor has been engaged. If the Nurse is urgently needed elsewhere, the Secretary reserves the right to recall her at the end of three weeks from the date of the confinement if the patient is well enough to be left. The Association does not undertake to nurse an unmarried woman in her confinement.

7.—Should the Association be unable to supply a Nurse and the Doctor considers one essential, a sum equal to the weekly fee will be allowed to the Subscriber until the Association can procure a Nurse.

8.—Classes 3, 4, and 5 will be asked to pay or provide for the Nurses' movements within the area of the Association.

9.—When night nursing is required the Nurse shall have six hours' rest during the day, and shall be off duty one night in three; she should be allowed some daily outdoor exercise; and to attend Divine Service.

10.—Forty-eight hours' notice must be sent to the Secretary before a Nurse is sent home.

11.—When attending a cottager's wife, the Nurse will be expected to do all that is required for the care of the patient's family, except the family washing.

12.—Nurses are forbidden to receive any gratuity, and do not expect beer or spirits.

13.—In cases of emergency, such as burns or accidents, a Nurse may be sent for without applying to the Committee Lady.

For further information apply to—

The Committee Lady for this District.

Sir,—To those of your readers who have the real interest of their profession at heart, the letters of Dr. William Milligan, "Parish Doctor," and "Country Practitioner," provide pabulum for serious reflection. It must be laid down once for all that a nurse can act only under the direct supervision of a medical man. I should like to ask these ladies, Who gave them power to create an inferior order of medical practitioner? The chairman of every nursing association should be a medical man in active practice. The fact is that medical men are afraid of offending ladies who have the power of procuring patients for them, or, on the other hand, advising patients to seek the advice of another colleague. Let us be more independent. If our duty demands that we shall act in opposition to some influential person, let us act fearlessly and care not for the consequences. Let us remember that by professional ability we do not mean the capacity to please some influential person, but our success in relieving or curing disease. We may lose a little financially at the time we oppose some pet scheme, but we shall gain the respect of our quondam enemies in the long run. Cases such as are cited should be discussed at the Divisional meetings of the Division in which they occur. Then a unanimously supported motion which could not be ignored should be sent to the offending committee. If the committee refuses to act in the matter, then a nurse who knows her duties should be imported into the district who would be supported by the profession, and the laymen or laywomen would soon see that they cannot ignore our profession.

The difficulty always is that there are always black sheep in the fold who are willing to suffer any indignity if they can gain monetarily by their actions. But it is quite time that we put down in a determined manner all these abuses. Can anything be more despicable than an educated medical man allowing himself to be controlled by a committee, and allowing an abuse to arise when he can plainly see that it is degrading to the profession of which he is a member? I think that in questions such as these we might make more use of the opportunity afforded by Divisional meetings for discussing these matters, and if we were only firm and united these abuses would soon cease. Let us fear no man, nor woman, remembering that *Magna est veritas et prevalebit*.—I am, etc.,

Bedford, April 9th.

S. J. Ross.

Sir,—So far your correspondents on this subject have been those who have found associations of this description a thorn in the flesh and objectionable. Perhaps the experience of one who has found them a considerable help and almost indispensable might now be recorded.

If the standard of the Queen Victoria's Jubilee Nurses be employed, the objections mentioned by your correspondents do not exist. A Queen's nurse may only work under the direction of a medical practitioner, and in the rules of the associations with which I have been connected it is distinctly stated that a nurse may only attend on receipt of a written order from a doctor, except in cases of emergency, and then only until a doctor can be summoned.

The three years' training makes the nurses extremely useful and also less inclined to take risks on their own responsibility.

There are now many county associations which are doing their utmost to raise all district associations to this standard, and by encouraging their efforts by every means at our disposal we have an effective method of remedying the evils complained of.—I am, etc.,

EDWD. P. FUEBBER.

Oxford, April 12th.

In addition to the numerous letters on this subject which have been published in full, we have received several others written in a large measure from the same point of view already stated with some fullness by others; we propose, therefore, to publish certain extracts only.

One correspondent, who signs himself "A Former Victim," gives an account of his experience of a local organization in connexion with a county association; it was managed by a committee of ladies; the local doctors were *ex officio* members having the privilege of subscribing a guinea a year, and of attending the annual meeting of the committee. To make any protest at this meeting, he says, was considered a hostile act attributable to mercenary and selfish motives. Our correspondent discussed the matter with the husband of the lady who took a chief part in the movement; this gentleman was a Tariff Reformer, and keen to defend his own business from unfair competition. In reply to an observation that though the loss of income to our correspondent through the association was a matter of no importance, yet to a poor man it would be serious, and that therefore, for the sake of the profession and for those who would come after him he protested, this gentleman answered that he could not consider the profession or posterity, but must make the thing pay. The nurse, though ostensibly engaged to attend the sick poor in their own homes, attended well-to-do people who had formerly employed a nurse from a nursing association, so that it came about that any one who paid 2s. a year obtained the services of the nurse. The local organization, therefore, competed not only with the medical but also with the nursing profession. In midwifery, our correspondent adds, no pretence was made of acting under medical supervision. Artisans, coachmen's wives, and many of the middle class who formerly employed the doctor had the nurse only. When the nurse attended, it was also necessary to employ some domesticated woman to look after the house during the lying-in. All parish midwifery fees soon disappeared; parish patients were advised to obtain orders, but not to use them unless the nurse failed to manage. The district was systematically touted by an army of female canvassers for support and subscriptions; the working classes paid 2s. a year, and looked upon it as a medical club. The only redeeming feature was the nurse herself. She was an exceptionally conscientious woman. I often wondered what would have happened if many other women had been in her position. She has gone now. The association is flourishing exceedingly, and pays well; it has helped to drive two doctors out of the district, and employs two nurses, who are "such a comfort."

Another correspondent writes from the south-west of England: "Here there are two nurses run under a kind of co-operative system, one a qualified midwife; there is a large committee, all women. I am allowed to subscribe to the funds but have no voice in their affairs. Touting is freely practised. The titled lady and the parson's wife survey would be promising cases of the small farmer's wife type, many well able to pay the guinea fee, saying: 'It is quite all right, you know. Nurse D—— is fully qualified; and, of course, if necessary you could call in the doctor if anything went wrong.' Something did go wrong a month ago. I was called at 3 a.m., during a pitiless fall of snow, about two miles out, to find a partially retained placenta easily removed. On the bed was a bulky volume on the science and art of midwifery. As I was driving off a dogcart drew up, the driver saying, 'I have come for nurse for Mrs. B.' Hearing this I re-entered the house, and proposed to attend this second case for the nurse. 'Oh, no, thanks very much,' she said; 'I'm off to it myself, and a neighbour can attend here very well now.' I may add I got 10s. and the husband's blessing."

A third correspondent, from the south-east of England, states that in his district one nurse left written prescriptions with her patients, and adds: "The Poor Law

guardians will subscribe to the nurse, but decline orders for midwifery to the district medical officer. Further, when a county nursing association was initiated, application was made that the question of remuneration to the medical men who were called in by the nurses should be considered. Needless to say, no satisfaction was obtained, and probably the matter was shelved. I finally resigned, on the ground, *inter alia*, that the association would not adopt any method to protect the nurse from attending on midwifery and infectious diseases at the same time. Moreover, it is distinctly unwise for any doctor to object to the nurse's methods, for should the association condescend to accept the doctor's word in preference to the nurse's, the only result, I apprehend, would be a reprimand for the nurse, and consequently the creation of a ceaseless enemy for the doctor. Recently a county court judge ruled that he would issue no commitment orders for rent where less than 5s. a head a week was coming into a house. Thus many a working man possessed of a wife and two children and a little cunning may practically never pay any rent at all. *A fortiori*, he need never pay the doctor."

ANTIVIVISECTION AND WOMAN SUFFRAGE.

Sir,—I notice in your article entitled "Antivivisection and Women Suffrage" that your modesty appears to preclude you from the use which I make of the word "female." What is the matter with "female suffrage" as English? "Woman" is a noun, not an adjective, and "woman suffrage" is not grammar. The Bible is good enough for me—"Male and female created He them," a text which is perhaps not inappropriate to the present controversy about female suffrage. However, while you blush at the word "female" your delicate taste does not prevent you from saying that a statement of mine is "false."

What I said at Bristol was that the inspectors were never instructed to make surprise visits, and my authority for that statement will be found at Q. 532 in the evidence before the Royal Commission, when Sir James Russell, one of the Government inspectors, was asked

"Have you been instructed to make surprise visits?" and he replied, "Never."

If it be true that as a fact some surprise visits are paid by the inspectors, the deduction I am entitled to make is that the inspectors have a better sense in their proper duty than the Home Office, which employs and instructs them; and my authority for saying that the inspectors were instructed "not to act as detectives" will be found at Q. 530, where Sir James Russell told the Commissioners that his superior officer "expressly said that I was not expected to act as a detective." No doubt you regard the only function of the inspectors to be to act as assurances to the public that nothing illegal takes place in laboratories; but the only way that can properly be achieved is for them to be present at every severe surgical operation, and to be diligent and alert to detect any infringement of the conditions of each vivisectioner's certificates.

Inspectors who decline to act as detectives manifestly can easily be deceived. Vivisectioners are not intended to be treated as above suspicion and as incapable of infringing the conditions imposed upon them; if they were, Parliament would not have enacted that there should be any inspectors at all.—I am, etc.,

Greywell, April 19th.

STEPHEN COLERIDGE.

* * * The word "female" in no way shocks the modesty which Mr. Coleridge is good enough to attribute to us. In the passage to which he alludes we took the liberty of referring to a little controversy in which he is not concerned. Would he be surprised to hear that he is not the only reader of the BRITISH MEDICAL JOURNAL? It is interesting to learn that he reads the Bible; this encourages us to hope that his scriptural studies may carry him as far as the precept, "Thou shalt not bear false witness against thy neighbour." He will thus learn, incidentally, that there is Biblical authority for the word which he thinks in bad taste. For our own part, we like to call things by their names, following in this the example of that recognized arbiter of literary taste, Boileau, who wrote:

J'appelle un chat un chat, et Rollet un fripon.

In regard to the real point at issue, which Mr. Coleridge as usual tries to evade, we refer him to the report of his Clifton speech as published in the *Bristol Mercury* of April 3rd, the accuracy of which he has not attempted to impugn. According to that report what he said was as follows (the italics are ours):

In the recent Royal Commission, the evidence of which was now closed, the officials from the Home Office told the Commissioners, in cross-examination, firstly, *that they never made surprise visits to laboratories*; and, secondly, in reply to the question as to what were the instructions given to them when they took office, the answer given was "not to act as detectives." It seemed to him that inspectors who were told *never to make surprise visits*, and also were specially instructed not to act as detectives, were practically inspectors appointed by the Home Office, whom they served, to be inefficient.

We showed that the inspectors stated in their evidence that their visits to laboratories were nearly always surprise visits, and that Mr. Byrne's replies showed that the Home Office took the fact that surprise visits are made for granted. Sir James Russell's statement that he had never been instructed to make surprise visits is a very different thing from Mr. Coleridge's assertion that the inspectors are told never to make surprise visits. We will not insult his intelligence by supposing that he does not appreciate the distinction; this leaves no room for any other conclusion but that his statements were made with the intention of misleading his hearers. In any case they are false. Mr. Coleridge's view that the proper function of inspectors under the Act is to act as detectives has already been dealt with, and it would be unprofitable to discuss it further.

"MEDICAL. AUTOMOBILISTS."

Sir,—I see that your issue of April 17th contains an editorial note in which you cite as "apocryphal" the history of a surgical emergency described by me in an unsigned letter in the daily press. I feel sure that you will be glad, as I now enclose my name, to correct this criticism in your next issue; for although the letter was for obvious reasons unsigned, it was clearly written by a surgeon, and you will agree that it will be a subject for serious regret should the public be led by your article to suppose that a member of the profession was prepared to press home an argument by romancing upon a point of fact. Allow me, then, to repeat that, thanks to the improved methods of highway transit, I had the opportunity two or three weeks ago of opening a cerebellar abscess, and of restoring the function of respiration, within some fifteen minutes of receiving a report of the case at a distance of over four miles from the patient.

The incident was of no great surgical interest, but it served to exemplify in rather a striking manner two points which the public and the authorities find it difficult to realize. It should, I think, bring home to the lay mind the fact, well recognized by all medical men, that a delay of a few minutes such as that occasioned by the interference of the police, may easily turn the scale between life and death. Secondly, it should disabuse the public mind of the erroneous idea (of the existence of which evidence has been shown by several letters and leading articles) that one doctor will serve as well as another in any particular case, and that if the surgeon in charge is absent, any one else who happens to be present will do as well. The incident in question exemplified the fact that whereas a highly-trained and unusually able house-surgeon regarded the condition as hopeless, another surgeon of wider experience took a more sanguine view and put it to the test.

I do not consider that I should have been doing my duty either by the patient or by the house-surgeon, had I requested the latter to undertake a somewhat perilous operation, under conditions calling for unusual expedition and without previous experience of the dangers which have to be avoided.

I am confident that any member of the community whose relative was in urgent danger of death would applaud the surgeon who travelled to his assistance with all available speed. I am equally confident (and I write as one who has himself driven a motor car about the streets of London many thousands of miles without an accident) in stating that the cab which carried me on this occasion at a speed averaging twenty-four miles an hour never for a moment put the public to the least danger.

I should perhaps add that the semi-suburban streets were at 10 o'clock on Sunday night more or less deserted.

We all agreed that the highway must not be rendered dangerous by the passage of motor cars at excessive speed; at the same time, many of us feel that public ends will be served if under special circumstances doctors' carriages are given a right of way such as that enjoyed by the vehicles of the fire brigade in this country and by ambulance carriages abroad.

Doctors are undoubtedly human, and should not be tempted to make use of a special privilege to serve their private convenience. I wish, therefore, to suggest that they should on occasions of urgency be empowered to make use of a distinctive sign, visible or audible, which will give them a right of way; that the use of this sign should in every case be reported by the police, together with the number of the car; and that the doctor should be bound to substantiate on oath the urgent character of his mission, *at a subsequent date*.

In a word, I think that the doctor should, in the interest of the public, be treated as a public servant, and that on urgent occasions his carriage should be afforded the same facilities, under the same restrictions, as those which it has always been thought politic to give to the vehicles of the fire brigade.

As your article and this letter may possibly be reviewed by writers in the public press, I will, if you please, enclose my name merely as a guarantee of good faith, and ask you to allow me to sign myself here—

E. B. W.

Universities and Colleges.

UNIVERSITY OF OXFORD.
Radcliffe Prize, 1909.

THE Master and Fellows of University College, upon the report of the Examiners, have awarded the Radcliffe Prize for 1909 to A. F. Hertz, D.M., Magdalen College, Assistant Physician, Guy's Hospital, for his dissertation upon the physiology and pathology of the movements of the intestines.

The College desires to call attention to a statement in the report of the Examiners to the effect that original work, in each case fully worthy of the prize, was submitted by the following candidates: A. G. Gibson, D.M., Christ Church; A. C. Inman, B.M., M.A., Wadham College. The next award of the prize will be in 1911.

Radcliffe Travelling Fellowship, 1903

At a meeting of the Radcliffe electors, M. W. Flack, B.M., M.A., Keble College. Demonstrator in Physiology at the London Hospital, was elected to a Fellowship under the Trust, on the report of the Examiners.

Oxford Graduates' Medical Club.

The summer dinner of the club will take place on Thursday, May 20th, at the Hotel Cecil. The chair will be taken by the President, Sir W. S. Church, Bart., K.C.B., and among the guests who have accepted the club's invitation to attend are the Chancellor of the University, the Master of University College, the Rector of Lincoln College, the Provost of Queen's College, and the two University Members of Parliament.

Lectures on the History of Greek Medicine.

Six lectures on the history of Greek medicine up to the age of Hippocrates will be delivered at the Examination Schools by Joseph F. Payne, D.M., Hon. Fellow of Magdalen College, on Wednesdays and Fridays at 5.45 p.m. :

May 5th.--The Background of Greek Medicine: Oriental systems.

May 7th.—Medicine in Homer: The Cult of Asklepios.
May 12th.—Greek Lay Medicine before Hippocrates: Public phy-

May 14th—Hippocrates and his immediate precursors: their relation to the Philosophers, etc.

May 19th.—The Hippocratic writings: more important of those now regarded as genuine.

March 21st.—The Hippocratic writings continued.

ROYAL UNIVERSITY OF IRELAND

THE following candidates have been approved at the examination indicated:

SECOND M.B.—S. R. Armstrong, T. P. Davy, N. B. Graham, E. A. O. M. H., J. J. Keirans, J. H. Mitchell, E. F. Moore, E. D. Staunton, W. F. Alges, J. Barragat, J. J. Barret, M. J. Cogran, S. H. Davison, B. Doyle, B. A. E. C. Fawcett, C. L. Gausson, J. M. Gibson, N. C. Graham, G. S. Harvey, G. H. Hayes, E. Heffernan, G. Jackson, James Lyons, John Lyons, S. McCoub, R. McCulloch, M. McGing, R. C. McMillan, I. W. Magill, E. W. Mann, R. Marshall, W. Megaw, A. G. Mitchell, H. R. Mulholland, J. O'Connor, P. Peol, J. M. Rowe, H. A. Skillen, J. Sweeney, W. B. Walker, W. B. White.

Upper Pass.

CONJOINT BOARD IN ENGLAND.

THE following candidates have been approved at the examinations indicated :

FIRST COLLEGE, (*Part I, Chemistry; Part II, Physics*).—G. Aspinall, Silvalva, C. H. B. Avarne, M. H. Barton, C. S. Baxter, W. A. H. N. Bell, J. H. Bennett, A. C. O. Brown, C. F. Burton, H. Chorley, G. Cock, G. R. Craig, T. H. Cresswell, R. W. Davies, H. R. Dive, A. J. Drew, H. Dudley, M. D. Evans, W. T. Floods, G. E. Francis, C. G. B. Fraser, J. L. Gibson, J. G. Smith, N. Hofmeister, G. G. B. Holroyde, E. L. Ivens, W. B. G. Jones, J. W. Kemp, T. R. Kenworthy, S. H. Keys, H. A. Kleberg, J. G. L'Etang, J. Lloyd, W. K. McKay, R. T. Macrae, D. D. Malpas, B. R. Mayman, A. D. Morris, A. G. Morris, P. Parker, H. H. H. Phillips, J. H. Pinner, J. R. Plenderleith, J. R. P. Penhale, G. S. Phillips, T. G. W. Pool, A. A. Prichard, C. S. Ramsay-Hill, S. W. G. Ratcliff, P. H. Rawson, J. G. Richards, G. M. Roberts, G. D. Robertson, J. W. Roe, H. A. Webb, J. P. Savage, A. G. Smith, J. H. Smith, E. A. Sutton, T. T. Taylor, E. R. Under, L. E. van Gelow, C. Wickless, G. H. D. Webb, E. R. Williams, F. Wilson.

FIRST COLLEGE Part II. *Elementary Biology*.—H. L. Addison,

² Part foonly. 1 Part I only.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

ELECTION OF EXAMINERS.

A MEETING of Fellows will be held on Tuesday, May 4th, at 4.30 p.m., pursuant to the provisions of the supplemental charter, to witness the election of Examiners.

The candidates will be chosen to serve on the following Courts: Conjoint Licence, Diploma in Public Health, Preliminary, Fellowship, Licence in Surgery (for registered practitioners), Licence in Midwifery (for registered practitioners), and Licence in Dental Surgery.

Candidates are requested to lodge their applications in writing with the Registrar, at the College, on or before Tuesday, April 27th, at 10 a.m.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examination indicated:

FIRST PROFESSIONAL.—J. P. English, J. G. Atkins, J. B. Barry, W. D. Beamish, J. Cockburn, J. T. Dier, L. C. Dillon-Kelly, J. J. Elliott, D. J. Healy, D. Leahy, J. S. Lewis, J. D. MacCormack, D. A. MacElean, F. Murray, M. Murphy, J. A. O'Driscoll, T. J. O'Riordan, A. F. I. Patterson, A. T. Rhatigan, T. S. Smith.
* Honours.

LONDON SCHOOL OF TROPICAL MEDICINE.

MEDICAL ZOOLOGY.

ARRANGEMENTS have been made for the holding of advanced courses in Protozoology, Arthropodology, and Helminthology.

three times a year. The subjects will be taken by the following lecturers: *General Medical Zoology*, Colonel A. Alcock, I.M.S.; *Protozoology*, Dr. C. M. Wenyon; *Arthropodology*, Colonel A. Alcock, I.M.S.; *Helmintology*, Dr. R. T. Leliper. The courses in the other subjects will be given during the first, fourth, seventh and tenth week of each of the three annual sessions of the school. Students will be allowed to attend the lectures on all the subjects or to devote the whole session to one of them. The lecturers will give a practical character to the courses throughout, and will be giving the students the opportunity to enable them to pursue unassisted investigations abroad or elsewhere.

SOCIETY OF APOTHECARIES OF LONDON

THE following candidates have been approved at the examinations indicated:

PRIMARY, PART I (*Biology*).—J. F. Bourke, P. R. Cross, J. E. Kitchen, L. F. Pain, H. E. Rose
Chemistry.—J. F. Bourke, P. R. Cross, J. E. Kitchen, W. A. Oaten, H. G. Steel
Matéria Medica and Pharmacy.—P. R. Cross, F. I. G. Hunter, R. E. Laurent
 PRIMARY, PART II (*Anatomy*).—H. Cox, H. N. Eccles, C. de C. W. Fensholt, F. J. Montgomery, F. G. Norbury, H. Rimington, R. A. Robinson
Physiology.—H. Cox, L. S. Davy, P. J. Montgomery, F. G. Norbury, H. Rimington, R. A. Robinson

Medico-Legal.

CHRISTIAN SCIENCE.

AN inquiry into the death of a lady who was living with a family of Christian Scientists and was attended by a practitioner of that persuasion was concluded at Sutton on April 15th. The jury brought in a verdict to the effect that she died of phthisis and that there was no criminal neglect, the people with whom she was staying having done their best according to their belief. To their verdict the jury added the following rider: "We are of opinion that had the deceased received proper medical advice instead of trusting to Christian Science treatment her life might have been considerably prolonged."

The evidence showed that the deceased had been suffering from phthisis for some years, and until January, 1908, was under ordinary medical care. About that time she became a Christian Scientist, and, after receiving Christian Science treatment for some time in her own home, moved to Sutton. There she died about three weeks later, while still under the same form of treatment. The master of the house in which she died produced a letter from the deceased, which stated that she was at Sutton by her own request and wish, and at no one's solicitation; that she had been tenderly and carefully nursed by the lady of the house since the date of her arrival, March 8th, and without reward or remuneration, except that brought by good actions; and that when she came the master of the house proposed to call in a doctor, but she objected. The lady of the house said the deceased had told her that if things came to the worst she was to call in a doctor to save trouble.

Evidence respecting the case was given by three medical men. Dr. Hooper of Sutton stated that he was asked to visit the deceased on March 18th, and on arrival was informed in answer to his inquiries that he had been sent for in order that if those responsible might keep within the law. He replied that if that was the only object in sending for him they had sent for the wrong man. He found the patient's condition desperate, and hence directed that the doctor who last attended her should be summoned. Eventually he made a *post-mortem* examination. He had never seen a body so much wasted, and its condition convinced him that the feeding of the patient had been improper. The patient should have had a nurse. He had no doubt at all that, with proper care and treatment, her life would have been prolonged, possibly for years.

Dr. Bellamy of Kew, in whose hands the case originally was, said he had not seen the patient between January, 1908, and March 19th, 1909, when he was called in, and found her practically dying. If in the interval she had had proper medical treatment her life would certainly have been prolonged, and perhaps for many years. From her surroundings he saw that the patient was not having proper attention. The owners of the house told him that there was no such thing as pain and no such thing as death. He never argued with Christian Scientists because he knew it was useless, but warned the master and mistress of this house that the patient was likely to die in a few days, in which case there was likely to be trouble. On their replying that they had called in a doctor, he informed them that they would nevertheless have to get a death certificate, and that no doctor ought to give one. He himself would not give one.

Dr. F. S. Toogood of Lewisham in reply said he had not seen the deceased during her life but had been present at the *post-mortem* examination. He found no evidence of insufficient nursing but would not say that the food given was suitable.

The Christian Science practitioner in whose charge she was when she died said he had only seen her once after her arrival at Sutton. He treated cases daily, and charged for them. The treatment consisted not in physical measures but in prayers; God did the healing. He had no knowledge of disease, but God had. He had not failed in his treatment because he could not fail. It was not due to failure of treatment that the patient died, but to some other cause. If he explained what that cause was it would not help.

MEDDLESOME FRIENDS.

AT an inquest in Marylebone on April 20th Dr. Danford Thomas, the coroner, took an opportunity of throwing into relief by his questions and observations the folly of the parents or other relatives of a patient interfering with the treatment of the medical man in whose care the patient is. The case was one in which an inquest was held owing to a medical certificate being obtainable. A medical man had been in attendance for some five weeks, but had refused to attend any longer because the parents of the child, owing to the interference of friends, neglected to carry out his instructions, and did other things which they ought not to have done. Another medical man was summoned, but did not arrive until after the child was dead. In view of the possibility of a question being raised as to the correctness of the treatment, the coroner in this case called upon a special pathologist, Dr. Spilsbury of St. Mary's Hospital, to make the *post-mortem* examination. His evidence was to the effect that the child died of bronchopneumonia, and that the medicine which had been prescribed by the medical man in attendance was of a kind suitable to the case.

STATUS LYMPHATICUS.

AN inquiry was held by the Coroner of the City of London on April 19th on the body of a child, aged 5, which died at St. Bartholomew's Hospital shortly after the cessation of the

administration of chloroform. Evidence as to the cause of death was given by Dr. Spilsbury, Pathologist to St. Mary's Hospital, who stated that the child was suffering from status lymphaticus, a condition in which death from sudden cardiac failure was peculiarly liable to be brought about by any depressing cause. The jury found that the child died from syncope while partially under the influence of chloroform, and suffering from status lymphaticus, after undergoing an operation skillfully performed.

MEDICAL REGISTRATION IN AUSTRALASIA.

ANTIPODE.—(1) The M.D. degree of the University of Louisville, Kentucky, U.S.A., is not registrable in the United Kingdom. (2) Registration in a Colony gives in itself no right of admission to the *Medical Register of the United Kingdom*; but the degrees of most Colonial universities are registrable here. (3) According to the report on unqualified practice issued by the General Medical Council last year, the legal qualification to practise medicine and surgery in New South Wales is registration by the Medical Board of the Colony, and this is granted to any person who proves to the satisfaction of the Medical Board that he is a Doctor or Bachelor of Medicine of "some university," that he has passed through a regular course of medical study of not less than five years' duration in a school of medicine, and that he has received a degree which entitles him to practise in the country where it was obtained. This last condition checks the registration of persons possessing such degrees as our correspondent describes, but when the law was passed in 1898 exemptions were made in favour of practitioners who had passed through a due course of study at a recognized school of medicine and surgery, and had practised in a reputable manner in New South Wales during the five years previous to the passing of the Act; these exemptions were in accordance with the precedents established in this country when the Medical Acts were passed.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

SUPERSESSION.

T. K.—In the circumstances mentioned the choice of the dissentient attendant should rest with the patient, who cannot be compelled to accept the services of the practitioner to whom he had in the first instance applied; but if the patient had wished Dr. A. to attend, Dr. B. would have had no just cause of complaint although he was the first to see the case.

The Services.

ROYAL ARMY MEDICAL CORPS (TERRITORIAL).

OFFICERS AVAILABLE ON MOBILIZATION.

M. I. T. S.—In the event of the Territorial Force being mobilized the medical officers, whether "available on mobilization" (formerly called *à la suite*) or otherwise, would serve in the rank stated in the *Army List*, and take precedence and draw pay and allowances accordingly. The only officers with the rank of Colonel are the administrative officers of divisions. No demands are made on the time of officers "available on mobilization" during peace. In organizing for the first time the staff of officers "available on mobilization" it has been necessary to give the seniors high rank at once, but in future it is, we believe, intended that they shall be appointed and promoted as those on other lists. It is very unlikely that an officer changing from one unit to another would be reduced in rank. In all cases a Major would take precedence of a Captain.

EAST ANGLIAN DIVISION.

A VERY interesting and successful function took place in Cambridge on Wednesday, April 7th.

Colonel Howard Marsh (Master of Downing College), the Honorary Colonel of the East Anglian Division R.A.M.C.(T.), issued invitations to all the medical officers in the Division to a dinner in the Hall of Downing College. Thirty-five officers accepted, and were present at the dinner, most of whom spent the night in Cambridge, either with private hosts or in the College hall.

After the loyal toast had been proposed from the Chair, and highly honoured, a most instructive and interesting after-dinner speech was made by Colonel Macpherson, R.A.M.C., who dealt in a most clear and able manner with the whole of the organization of the medical department of the Auxiliary Forces, from the base to the firing line, including such important points as treatment at the front, transport, rest hospitals, general hospitals, and nursing. He alluded to several matters at present under consideration, including the fee for examination of

recruits, equipment of units, etc., and contrasted our system with that obtaining in some Continental armies. He also dealt at length with the sanitary side of the service, and ended with an earnest appeal to those present to do their best to bring about the success of the scheme.

An interesting discussion took place after the address, many questions being asked and answered by Colonel Macpherson.

A vote of thanks to the speaker of the evening was proposed by Lieutenant-Colonel Sims, seconded and seconded by Colonel Lyon, V.D., Cambridgeshire Regiment.

Among those present were Colonel G. S. Elliott, A.M.O., East Anglian Division; Major Freeman, R.A.M.C.; Lieutenant-Colonel Griffiths, R.A.M.C.(T.), commanding the 1st East Anglian General Hospital; Lieutenant-Colonel Bradbury, Lieutenant-Colonel Wherry, Lieutenant-Colonel Deighton, Lieutenant-Colonel S. Hoyland, and Lieutenant-Colonel Bindloss.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

HOUSING, TOWN PLANNING, ETC., BILL.

THE general scope of Mr. Burns's bill to amend the law relating to the housing of the working classes, to provide for the making of town planning schemes, to make further provision with respect to the appointment and duties of county medical officers of health, and to provide for the establishment of public health and housing committees of county councils, was indicated in the report of the second reading discussion published in the JOURNAL of April 10th, p. 921, but a few additional details may usefully be given. It consists of three parts:

Part I contains chiefly a number of amendments of procedure of the Act of 1890, strengthening the powers of local authorities to deal with dwellings unfit for human habitation and in particular requiring the establishment by every local authority of a quinquennial survey and register of housing accommodation for the working classes within the area administered by the authority. Another important provision in this portion of the bill is the extension of lodging-houses for the working classes from inhabited house duty and the total prohibition of back-to-back houses.

Part II deals with town planning, and not only gives powers to local authorities to make schemes for the laying out of land in the neighbourhood but also has provisions to compel a local authority to make or execute a town-planning scheme where one ought to be made, or where one proposed by owners of any land ought to be adopted; the provisions of this part of the bill will seem calculated to effect great improvements in the present condition of affairs.

Part III is particularly interesting to the medical profession because it deals with county medical officers. The first section obliges every county council to appoint a medical officer of health, while subsection 3 prohibits part-time appointments in future. Subsection 5 enacts that a medical officer of health of a county shall be removable by the county council with the consent of the Local Government Board; and otherwise, and subsection 6 provides that a medical officer of health of a county shall not be appointed for a limited period only. These two sections, if they become law, will give permanency to the positions of medical officers of health. The bill also provides that a county medical officer of health will not be allowed to engage in private practice or to hold any other appointment. Clerks and medical officers of health of district councils are required by section 58 to supply county medical officers of health with any information which it is in their power to give, and which the medical officer of health for the county may reasonably require for the purpose of his duties. Section 70 compels every county council to establish a public health and housing committee to which shall stand referred all matters relating to the exercise and performance by the council of its powers and duties as respects public health and the housing of the working classes, but the London County Council is exempted from the application of this section. Section 71 permits county councils to promote the formation and extension of building societies having for their object the erection or improvement of dwellings for the working classes, and to assist such societies by making grants or advances or guarantee advances; the councils are given power to borrow money for these purposes.

OLD AGE PENSIONS AND RELIEF IN POOR LAW INFIRMARIES.

A CIRCULAR dated April 16th, issued by the Local Government Board to local pension committees and subcommittees, contains the following paragraph:

"The Board may also take this opportunity of stating the view on which they have acted in refusing applicants made to them in cases where the claimant has been an inmate of a Poor Law infirmary. The question whether maintenance in the infirmary comes within the provisions of Section 3 (1) (a) (i) or (iii) of the Old Age Pensions Act appears to them to depend upon the circumstances of the particular case. It is somewhat difficult to lay down exact rules for such cases, but the Board's view is, generally, that if a person suffering from an illness or an accident has been received in a Poor Law infirmary for cure or treatment, he is not thereby disqualified, such relief as he obtained other than surgical or medical assistance, being merely incidental to such assistance. If, however, he became a chronic inmate of the infirmary the medical character of the relief would cease to preponderate and disqualification would ensue. The same principles apply in the case of an inmate of the sick wards of a workhouse, the actual place where the poor person is lodged being of less importance than the nature of the relief afforded to him."

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL are at 423, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 423, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 423, Strand, London, W.C.

TELEGRAPHIC ADDRESSES.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Atiology, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National):—

2531, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2530, Gerrard, BRITISH MEDICAL ASSOCIATION.

2534, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 423, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED. In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

DR. DRINKWATER (Wrexham) desires to hear of a home where a girl, aged 19, suffering from chlorosis and just recovered from phlegmasia alba dolens of both legs, would be admitted.

PETIT BREATH.

HEALTH OFFICER asks for information as to the usual cause of petit breath apart from such well-known conditions as dyspepsia, dental caries, and ozena.

* The probable cause of foul breath under the conditions named is slight catarrh of the cavity of the mouth, nose, or pharynx, associated with the presence of various aerobic bacteria, such as *B. mesentericus*, *B. pyogenes foetidus*, *B. lactis aerogenes*, *B. proteus fluorescens et septicus*, or with some less definitely known anaerobic organisms, but we know of no medical book in which these relations are discussed.

INCOME TAX.

E. M. C. asks whether the surveyor of taxes is within his legal right in demanding from him accounts for the years 1905, 1906, 1907, and 1908, and also whether he is correct in stating that no deduction can be made for the cost of additions to a practitioner's stock of instruments.

* The surveyor has no direct power to demand accounts. His functions, however, include the verification of the amounts returned by taxpayers for assessment, and it is doubtless in this connexion that accounts have been asked for. Our correspondent may refuse to furnish the accounts at this stage; but in that event the Commissioners would probably decline to accept his return, and would make an estimated assessment upon him in any amount they thought fit. In order to obtain a reduction of this assessment accounts would have to be produced, and therefore it is simpler for all parties if accounts are sent to the surveyor in accordance with his request. The cost of additional instruments is regarded as an outlay of capital, for which no deduction is allowed under the Income Tax Acts. This view is obviously open to criticism, but it is to be feared that individual protests are not likely to receive much consideration.

ANSWERS.

PRACTITIONER.—(1) A good anatomical atlas for use by a person who cannot attend a dissecting room is *The Edinburgh Stereoscopic Atlas of Anatomy*, edited by David Waterston, (Edinburgh: T. C. and E. C. Jack). (2) A good articulated skeleton costs about £3. Price lists can be obtained from Messrs. Millikin and Lawley, 165, Strand, London, and M. Trautmond, 9, Rue de l'Ecole de Médecine, Paris. (3) Gould's *Illustrated Dictionary of Medicine, Biology and Allied Sciences*, 1900, 4fs., and Gould's *Dictionary of New Medical Terms*, 1905, 2fs. (London: Baillière, Tindall and Cox), are good modern dictionaries of medicine and surgery.

SUICIDAL TENDENCIES.

G. P. W.—A satisfactory opinion could only be given after an examination of the patient. She may be a mental degenerate with a bad family history, or she may have had a decided attack of melancholia. She should be carefully examined to see whether her condition is such that she can be certified and placed in the county asylum. If there is any recurrence of the suicidal attempt, it might be a good thing to bring her before a magistrate, because the appearance in court is often of great advantage in hysterical cases by inducing more self-control. If the girl is not pregnant, there would seem to be even now some evidence of delusion; if she is pregnant, the case is probably one of melancholia of pregnancy, and she should be placed in an asylum, unless she has friends who will take her and be responsible for her safety. It does not appear that there are any homes or institutions which undertake cases of this description. Patients of this kind are always uncertain, and it is very risky to keep them as servants in families. She requires protection until her general health is re-established, and apparently this can only be obtained by her own friends or in some curative establishment. No hospital would be likely to undertake the case. There is no statement as to whether some small money payment could be made with the girl. If she could pay a little, it might be advisable, should it be possible to place her under certificates, to apply at the Handford Home for Feeble-minded Girls. Apply to Miss Jeffries, St. Helen's Lodge, Ipswich, or to the Secretary, National Association for the Feeble-minded, Denison House, 296, Vauxhall Road, S.W.; terms, 10s. a week.

PRACTICE IN CANADA.

M.D.—(1) In British Columbia a medical man can obtain registration on the strength of qualifications derived from Great Britain or Ireland only if he was registered in Great Britain or Ireland previous to June 30th, 1887, otherwise he must undergo an examination. There is a fee for registration which "must not exceed 100 dollars." Application for registration should be made to the Registrar of the Medical Council, Victoria, British Columbia. (2) In Manitoba the most recent Medical Act appears to make it permissible to admit to the Register any practitioner holding a qualification entitling him to registration in Great Britain or Ireland; but as there is some obscurity in the wording of the Act, inquiry should be directed to the Registrar of the College of Physicians and Surgeons, Winnipeg, Manitoba. (3) In Alberta a medical man desiring to obtain admission to the Register on the strength of qualifications derived from Great Britain or Ireland must, according to the Medical Act of the province, pass an examination "touching his fitness and capacity to practise medicine, surgery, and midwifery." The examination fee is 50 dollars, in addition to a registration fee of the same amount. The registration authority is the College of Physicians and Surgeons, Edmonton, Alberta. (4) In Saskatchewan the regulations are on all fours with those of Alberta, the registration authority being the College of Physicians and Surgeons, Regina, Saskatchewan. (5) In each case a statement of the candidate's qualifications and their dates should be submitted to the registrar of the authority in question, and precise information obtained as to the requirements he will have to fulfil. (6) In the older towns hospitals are staffed much as they are in England, but elsewhere they are sometimes administered in the same fashion as are cottage hospitals in this country. There is no one rule, and the conditions which will have to be dealt with on this respect are only determinable when the choice of a new home has been finally made. (7) There are plenty of medical men in all parts of Canada making incomes of the amount stated—namely, £500 to £1,000 per annum. Relatively these sums represent in most parts of Canada a somewhat smaller income than they would in this country, and whether any individual medical man proceeding from England could make either of them, even if "a fair surgeon" is a purely personal question. There are a good many medical schools in Canada, and these annually turn out a large number of excellently qualified medical men; nevertheless, the population is rapidly growing, and there is doubtless room for immigrant medical men of real ability and industry and possessed of sufficient capital to support themselves while making a position. In itself, however, the holding of a British qualification is no special advantage, and a practitioner born and bred in these islands would have to become socially acclimatized before he found himself on equal terms with his Canadian-born competitors.

LETTERS, NOTES, ETC.

JEWS AND ALCOHOLISM.

DR. C. F. MARSHALL (London, N.W.) writes: In your article on this subject in the *BRITISH MEDICAL JOURNAL* of April 17th, it is stated that "alcoholism occupies the first place as the causative influence of insanity." This statement is open to contradiction, for the researches of Mott and others show that the first place should be given to syphilis. If it is true, as stated in your article, that degeneration of the nervous system and insanity are more common among the Jews than other races: this tends to indicate that the alleged rarity of syphilis among the Jews has been exaggerated.

THE LONDON UNIVERSITY AND COLLEGE QUESTION.

DR. H. ELLIOT BLAKE (Bognor), in the course of a long letter on this subject, writes: In the latest discussion of this

question to again descend to the arena of alternatives is unnecessary. Dr. Mercier has yet one other solution—that of registering an M.D. for the collegiate licences by the aid of a special charter; but I fail to see how it applies to the last year's determinations to readjust the university and to hold a Royal Commission, which produced the College Committee of Inquiry. However, through a complex division of doubts he admits the difficulty of avoiding this much-talked-of exchange of title to an M.D. for the diplomats. What will be appreciated by Members is his recognition, as one of our leaders of the justice of the Members' claim to be considered on a parity with their university or "provincial colleges." But, as to the new solution, a new charter would simply retain the tattered pall and fenestrating furnishings of a decadent past and the continued ill-working of the collegiate system.

The difficulty Dr. Mercier quotes of the apparent stumbling-block of adapting the matriculation is not insurmountable, if only the half measure of adaptation be dropped and the necessity for a change be acknowledged. Thus, by accepting the existing colleges' preliminaries for, say, one or two years, and then introducing any agreed upon level for all acceptable preliminaries, that question would be solved. If a further arts course were required, at a future time, the university could well provide for it.

The colleges have been found fault with for splitting their own new committee's purpose and leaving action to be taken by the Royal Commission. I do not hold with such convenience or expediency, and think that the committee of the colleges should not abate one iota of their previous intention of entering into direct negotiations for any compact of agreement that may be decided upon with the University of London and with the authorities alone concerned on both sides. They are strong enough in the foundation of this reform, they have a practical senate as the only legal executive to deal with, and the medical faculty and other leaders are not at all adverse to treating them favourably. They should not forego the advantage of position after so long and strenuous fight. If the Royal Commission ratifies these agreements all the better.

[The remainder of Dr. Blake's letter deals with matters affecting the internal economy of the University of London, which we venture to think more suitable for discussion before the Royal Commission than in these columns.]

TREATMENT OF RINGWORM IN SCHOOL CHILDREN.

DR. HORACE MANDERS (London, W.) writes: As Dr. Galbraith (*BRITISH MEDICAL JOURNAL*, April 17th, p. 983) has asked help from the experience of others to clear up the doubts and difficulties under which he labours, I can refer him to the last report of the East London Hospital for Children. We do not claim anything marvellous, but we can show most excellent results by means of x rays. In the large-spored variety the cure is speedily effected, sometimes the small-spored variety gives a good deal of trouble. I may add that a great deal depends upon the general health of the individual children. I cannot call to mind any case that has not eventually become cured, neither have I seen any deleterious action upon the skin. I shall be very pleased to show him cases under treatment at any convenient time, and demonstrate the technique. Unless the latter is understood, and the treatment retained in the hands of those who have been trained to the work and duly qualified to interpret symptoms, serious mischief is bound to occur. Under proper conditions, on the other hand, my experience is that no other treatment can approach that of x rays in efficacy and in shortness of time. Our average number of sittings for each case at the East London Hospital is between six and seven.

"ANTIVIVISECTION AND THE POOR."

A DISGUSTED RADICAL writes: It is remarkable but depressing fact that the *Daily Chronicle*, which I for one have been accustomed hitherto to consider as the representative of sane Radicalism, should on a single page to-day contain a panegyric of homeopathy, by one of its leading practitioners: a ridiculous statement about the nourishing properties of spinach, in a letter by a correspondent of some social standing; and a still more preposterous glorification of H. C. Chadwick, at the expense of Edward Jenner, as the exterminator of smallpox, in another letter. The correspondent who also occupies some position in the commercial world. How can we wonder at the readers of newspapers falling victims to such misleading nonsense, when editors find it consistent with their sense of responsibility to give a place to it in their columns?

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	—	—	0 4 0
Each additional line	—	—	0 0 6
A whole column	—	—	2 13 4
A page	—	—	8 0 0

An average line contains six words.
All remittances by Post Office Order must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

An Address

ON

THE DUTY OF THE MEDICAL PROFESSION IN THE PREVENTION OF NATIONAL DETERIORATION.*

PRESIDENTIAL ADDRESS DELIVERED BEFORE THE MANCHESTER
MEDICAL SOCIETY.

BY WILLIAM COATES, C.B.

It is difficult in all countries to obtain statistical evidence which proves conclusively that a population has improved physically or the reverse. It is more difficult here, as detailed records are only available from army reports; and, as conscription does not exist, the measurements and weights taken only apply to a limited section of the community. But none of us who know the influence on health and strength of fresh air, good food, abundant light, and varied exercise, can doubt that—now more than 77 per cent. of our population live in big smoky towns, where dwellings are overcrowded and often densely packed together, with very little open space; where rapid transit is so easy and little exercise is taken; where the bad influences of drink and vice abound—degeneration is taking place. Those who oppose this view argue that a large proportion of the people classed as urban really live in wholesome suburbs, and that nutritious food is more easily obtained by the poorer classes than formerly. But there is a vast difference between a suburb and the country, and it is questionable whether our present dietaries are superior to the old. Mr. T. C. Horsfall, J.P., one of the foremost and most laborious workers in all spheres of social reform, has brought under my notice two valuable opinions bearing on this point. Dr. Grotjaun, after most exhaustive investigation, is convinced that the old diets of rye-bread and milk in Germany, and oatmeal, barley-meal, and sweet and butter milk in this country, gave better results than the tinned foods, bad fried fish, stewed tea, pickles, and other unwholesome and badly-cooked food upon which poorer parents often feed their children now. Admiral Bosanquet, who has been largely concerned with the training of boys for the Royal Navy, says that the finest boys come from the West of Ireland, where they have been mainly brought up on potatoes and fresh air. These boys hate the meat supplied to them in the navy, and often drop large portions of it into the sea. The same authority gives some striking statistics bearing upon physique. Owing to the popularity of the service and to the good pensions given, a large number of boys of classes higher than those that enter the army try to enlist. On an average 5,000 boys are needed annually; to get these 35,000 are rejected.

My own attention was first drawn to this subject twenty-five years ago by observing the poor physique of many young men who presented themselves for enrolment in our voluntary forces. During the intervening years I have had constant opportunities of observing not only our volunteer recruits but also the regular troops stationed at the Hulme Barracks, at which station from time to time I have had the medical charge of the hospital, and have conducted the medical examination of army recruits. Year after year the increasingly wretched physical condition of the majority of youths appearing for examination has deeply impressed me.

The standard for admission into the army is lower than in former years, and more men are examined and rejected before casualties are replaced. Statistics relating to the physique of recruits who have, in various years, tried to enlist into the British army cannot be regarded as conclusive, as a particular class of person must not be selected and relied upon to verify a universal truth, but in this country there is no other source where similar records have been kept.

Fifty years ago, as now, a recruit could enlist at the age of 18 years. The minimum height was then 5 ft. 4 in. It is now 5 ft. 3 in.; fifty years ago, however, a height of

5 ft. 4 in. would only admit a recruit into the army as an artillery or engineer driver, and the number required was small; 5 ft. 6 in. was the height for a line regiment; 5 ft. 3 in. will enter a recruit into any line regiment now.

Previous to 1883 a recruit could not enter the army unless his *minimum* chest measurement was 34 in. He can now enlist into some units with a chest of 31½ in., provided he has 2 in. expansion.

In 1862, 416 recruits per 1,000 weighed under 9 st. 4 lb.

In 1907, 657 recruits per 1,000 weighed under 9 st. 4 lb.

In 1862, 52 recruits per 1,000 weighed under 7 st. 12 lb.

In 1907, 83 recruits per 1,000 weighed under 7 st. 12 lb.

Fifty years ago, when the physical requirements for enlistment were much more stringent than now, 37 per cent. only of the recruits examined were unfit for service. In 1907, 39 per cent. were rejected by the medical officer; and General Sir Frederick Maurice considers that, when the numbers that are sent away by the recruiting sergeants and those dismissed as unfit after three months' service are taken into account, at least 60 per cent. are now lost to the army through physical unfitness.

This obvious deterioration of the class from which recruits are drawn is condoned by reference to unemployment and starvation; but these agencies have not been proved to be much more active now than in earlier times, taken over a series of years, and as the physical standard for admission into the army has been so often and progressively reduced, until it is now lower than ever before during peace, and as the population of the country is vaster by millions, the figures quoted should cause apprehension.

The foregoing particulars are given as evidence of physical degeneracy; but they are by no means relied upon to prove it; stress is laid rather on the mental than on the physical aspect of the case.

The previous figures do not apply to the whole population, but in Germany and other countries where conscription exists, the evidence is much sounder. It proves that the country places supply a much larger proportion of robust recruits than the towns, especially the larger towns.

You will not wish me to carry this question further. All will agree that there is at any rate deterioration enough to call for serious effort on our part to arrest its progress.

More Co-operation in our Profession Required.

The first point that I would submit is that more co-operation, more cordiality, is wanted in our profession if it is to become effective in its warfare against deterioration. All branches of the profession must be more closely welded together—the consultant, the teacher, the medical officer of health, the school medical officer, the general practitioner, all State-employed doctors. The work of each must be so interlinked with the other that broader views become possible, the corners of specialism rounded, the interest and special knowledge of the family doctor maintained and made use of; the collective experience of the whole co-ordinated.

At present no chain exists, only isolated links; some of them are strong, others weak. No serious attempt has been made to join them firmly together. The metal of most of the links has been well tried, and is sound, but a few of them contain flaws that can only be removed by reforcing. It must be remembered that the strength of a chain is that of its weakest link.

Some of you will say that race degeneracy is the province of the public health specialist, and that he is reducing the risk of disease every year. But he is not so much concerned with the strengthening of the stamina as he is with the preservation of the race. He is catering for a weaker constitution, one that in olden days would have died in infancy or early youth. This is the tragedy as well as the glory of the problem. Life must be preserved; it is not for us to consider at the moment the effect upon that life or others, that the prolongation of a life entails. If the health medical officer is to accomplish much, he must work hand in hand with the family practitioner, and remember his perplexities, and the latter should be ready to do more than simply accept the privileges which the former offers him.

Our teachers, too—I say this with great respect—are not blameless. They attach so little importance to public

* In printing this address some introductory remarks and also some passages in the earlier part have been omitted owing to considerations of space.

health and other kindred subjects. Nothing is done in the student career to teach "brotherhood" amongst the various branches of our profession, nor responsibility concerning the improvement of race stamina. Such matters are as seldom touched as those equally important ones of medical ethics and a practitioner's difficulties—problems which confront the latter so seriously during all periods of his career.

Increased Powers to Education Authorities.

Those interested in national health look for good results from the powers entrusted to the educational authorities by the Education (Administrative Provisions) Act, 1907. This gives authority to carry out a systematic inspection of all children attending the public elementary schools, and also to make provision for the benefit of their health and physical condition.

Until recently, with perhaps the exception of advice regarding vermin, and very minor ailments, all cases in which a child required medical advice have been referred to the family doctor, or in necessitous cases to a hospital. Under the extended powers that have now been given, the institution of school clinics for the treatment of medical and surgical cases is contemplated, and in some towns, notably Bradford, are already in operation. A perusal of the report of a Special Subcommittee of the London Education Committee on this subject, which favours such proposals, fails to convince me of any necessity for these clinics, nor of any need to subsidize general or special hospitals for the treatment of public elementary school children. It does, however, give grounds for apprehension that their adoption would seriously injure the rights of the profession, and that many children with parents well able to pay would receive gratuitous treatment. Ailing children should be referred to the family doctor, and cases requiring special treatment should be sent by him to a specialist, or in needy cases to a hospital. Hospitals exist for the poor; many are endowed for their service, and no more reason exists for the education authorities to make payments to hospitals than to private practitioners. The profession should appreciate the importance of this subject, and affirm their ability and readiness to co-operate. If the issue is left to chance the result will surely be serious.

Co-operation between the Medical Profession and Educationists.

Further steps should be taken to associate the whole profession more closely with those who control national education. If this were done the cultivation of sound health would be a more prominent feature and stronger generations would follow. Elementary teaching has been too much pressed forward and involved. Its form, length, and nature have been settled apart from any guidance by the medical profession. It is not contended that members of our profession are capable educationists, but I do maintain that by their experience and training they are specially fitted to lay down rules for the moral and physical training of the young. In our great public schools education is directed primarily to the training of mind and body—whereas, in our lower grade schools, the tendency has been to give the scholar the maximum amount of knowledge necessary to gain Government grants and local élat, at the expense of a training so necessary to the higher development, which now meets with no reward and but scant recognition. I submit that if the medical profession had been consulted *health and training* would have bulked larger and the imparting of actual knowledge smaller, in the elementary school system. "Learning" and "training" should go hand in hand. The value of each increases fourfold when incorporated with the other. It is not easy to differentiate between the two. It may not be strictly true to say that learning is represented by those things which we remember, and training by those which we have forgotten; but it will hardly be denied that our lives are more influenced by the many things we have heard, or read, or done, which we have forgotten, than by those we have been taught and remember.

Learning may be described as a definite substance, capable of being expressed in precise terms; it can be condensed into a textbook, it is encyclopaedic in character, and its conclusions can be demonstrated on a blackboard. It is an aggregation of units of knowledge; it is perception, and accumulated, no doubt, it is power.

Training is more difficult to define; it is a subtle amalgam subject to infinite and indefinite numbers and forms of influence and environment; it matures rather than increases, it becomes an integral part of the pupil, an instinct ever ready to assert itself in emergency, in fact, guide, philosopher, and friend through life.

It is not learning alone, but mainly *training*, which enables the British to control millions of alien races; and in my opinion we are justified in impressing upon the public that the training of the moral sense and physical capacity should be greatly extended in our educational system.

The higher aim of education should be to fit the young to become good and healthy men and women, husbands, wives, and parents; loyal citizens and patriots.

Value of Judicious Physical Exercise.

The value of well-ordered physical exercise, of athletic games, and gymnastics, must not be overlooked as remedial agents in physical deterioration. Improperly practised violent exercise does more harm than good, and will produce evils of heart, lung, nerve, and muscle. It is dangerous to allow weak and strong children to play together indiscriminately—without classification or superintendence. Not only in public elementary schools, but in all schools, private and public, the doctor should give individual advice on these points. The value of *progressive* Swedish physical exercises is now well known, and these are taught and practised in a modified form in many elementary schools. They should be given daily instead of once or twice a week, they should be practised in the open air and during school hours, and they should be regulated by the medical officer according to the condition of each individual child.

In the army, where every soldier must be made as strong, agile, and "fit" as possible, a new system of physical training was adopted in 1907, based largely upon a Danish modification of the Swedish exercises. The main principles are *progressive* exercise—an avoidance of overtax, the harmonious working of all parts of the body, and an awakening of the intelligence of the recruit. The tricks of the gymnast and acrobat and the practice of many difficult displays, useless from the point of view of general development, have been replaced by progressive training in Swedish movements, followed by boxing, wrestling, swimming, bayonet fighting, fencing, etc. The greatest possible development is aimed at without strain. Under the old severe system, which developed muscle as rapidly as possible, young soldiers were often permanently injured. Under the new system a great improvement in the development of the recruit follows, and the number discharged from the army as physically unfit after three months' service has been considerably reduced. But in the army these exercises are carried out under the immediate supervision of the medical officer, who, having himself been through the training, regulates its application to individual needs. It is equally, if not more, important that children of every class should be under medical supervision during school life so that individual weakness may be counteracted and overstrain avoided. It is not to supersede school games that these exercises are advocated, but to supplement them. Games are of the greatest advantage, and make boys fearless, alert, and strong; but harm is sometimes done which medical supervision would prevent. In the case of girls, too, sufficient care is not exercised. Contrary to the experience of the public elementary schools, I have been able to satisfy myself from a number of examinations of boys and girls of the better classes attending preparatory and public schools that growth in both height and weight and general development takes place to a greater degree during the school term than during the holidays.

Playing Fields.

Can we, as a profession, do nothing to encourage our civic authorities to provide playing fields for the youth of our city? The Education Committees of Manchester and other large towns have made a wise concession in throwing open the school playgrounds during the summer months until dusk and during holidays. But this is not enough. The child must be less confined—more in different and fresher air. The Education Act, 1907, gives extensive

powers, and if the importance of playing fields for children is brought forcibly to the notice of the authorities something may be done in this direction. In Manchester and Salford a "playing fields society" was started a year ago. A field of 33 acres has been acquired at Gorton, where the working lads of the city play their games under kindly supervision; 800 lads can be seen there every Saturday afternoon and summer evening. The profession should give its heartiest support to such a beneficial movement. Games have always been a distinctive feature of English life, and they should take a foremost place in child training. They ensure fresh air, they cause delight, they help to form character and public spirit, and they can be made a means of promoting good physical development. Public gymnasiums should be provided by the municipality in all large towns where out-of-door exercise and field sports are difficult to obtain.

Diminishing Birth-rate and Marriage.

The serious decrease of the birth-rate in this country is intimately connected with physical degeneracy on the one hand and with the responsibility of our profession in its prevention on the other. There is a decrease in both birth-rate and marriage in all the countries of the world except Ireland, some parts of Spain, of Austria and Russia. The exceptions are due to the stronger religious beliefs held in these places regarding marriage and its objects. The birth-rate per 1,000 of population in Manchester was in 1907 only 28.3; in 1871-75 it was 38.9; in 1881 35.9; in 1891 33.8 per 1,000. Manchester is by no means worse than other towns. In Nottingham during the last twenty-five years there has been a fall in the birth-rate of 30 per cent. There are two quotations bearing on this subject which have struck me. Gibbon, in his *Decline and Fall of the Roman Empire*, alluding to the condition of affairs in the Roman Empire in the days of Constantine, writes:

The horrid practice so familiar to the ancients of exposing or murdering their newborn infants was becoming every day more frequent in the provinces, and especially in Italy. . . . The less opulent or less industrious part of mankind, instead of rejoicing in an increase of family, deemed it an act of paternal tenderness to release their children from the impending miseries of a life which they themselves were unable to support.

The second is an extract from the report for 1907 of Dr. Niven, Medical Officer of Health for Manchester. He says:

There can unfortunately be little doubt that the continual descent of the birth-rate is due not merely to the prevention of conception, but also in no small degree to destruction of its fruits. If so, the effect both on natural selection and on the national habits must be injurious. The offspring must also be injured in many cases by the efforts made to bring on premature labour.

Is there no parallel between these two statements? The first was the practice in declining Rome; the second is a practice in this country to-day. There are two apparent differences. The Romans were brave enough to slay their children openly, and the male committed the crime; whilst now in this country the deed is done in secret, and the male expects or allows his mate to do the gruesome deed. The decline is not due to physical but to moral degeneracy. It is a deliberate act of the will, which is depriving the country of hundreds of thousands of babies annually. It is useless to hide these facts. Every practitioner is familiar with them; they are spoken of to him without a blush—nay, he is often tempted, and with no mean bribe, to be an accessory to the act himself. Ought we not as a profession to do something to check this waste, to restore the old pride and glory that parents originally felt in the propagation of their species? We have opportunities which no one else has. But there is no doubt of the fact that the parents who should be "stocking" the empire with healthy children—the more cultured, more prosperous, wealthier, and thriftier classes of the country—are shirking their responsibility, producing fewer children, and the country will soon be swamped by the children of the only people nowadays who procreate freely, namely, those who live in the slums, and our alien population. In former years these "possible undesirables" were swept away by epidemic disease, which science is now controlling year by year more and more. By reducing mortality, preventive medicine is the means of bringing to

maturity many weaklings who, in the absence of present-day knowledge, would not have got beyond early childhood, and who would not, therefore, have been able to hand on their shortcomings of weakly physique, with its want of power to withstand the strain of modern life. It is interesting in glancing through the obituary columns of old numbers of *The Gentleman's Magazine* of a hundred and fifty years ago, which was a sort of record of social and political events of any moment, to note the great number of people who died from small-pox, and to the number of women who died in childbirth. As, of course, only people of a certain standing in society would come into notice, the deaths throughout the whole population from these two preventable causes and other infectious ones must have been enormous. Many of these deaths are prevented now. Families of one, two, or three children are now the rule, and they are justified on grounds of thrift and health, when really in most cases the mania for pleasure and excitement, unwillingness to suffer inconvenience, and national irresponsibility, are chiefly the causes; this must result in national degeneration. Our plea is not necessarily for large families—these are sometimes potent as factors in the cause of deterioration—but that to regulate the size of a family by any other means than mutual self-restraint and self-respect must be demoralizing and productive of harm. It is where the children cause the most inconvenience that the decline is chiefly noticeable—where married women earn wages, and where social life is most interfered with.

It should be remembered that if marriage were regulated by the State a robust race could soon be raised; but this is not feasible, and any serious interference with the process of natural selection would rightly be regarded as sacrilege, and resented by all classes.

The subject is full of difficulties. How is it possible to limit the ever-increasing number of children born to the unfit in our slums? Can some system of race culture be made fashionable, so that the finer specimens of British humanity may take pride in producing a strong and noble race?

Should not the State give privileges to those with large healthy families, and try to make the rearing of children an attractive occupation to women of a fine type? Some graduation in the income tax, privileges in connexion with education, or facilities for entering the public services might appeal to the better-to-do, and some advantages in food and clothing and in municipal employment might be an inducement to the better working class. This generation might be the losers but later ones would benefit; and if those who pay taxes have the subject brought home to them, there will be a better chance of "curbing" negligent and thriftless parents.

It is a great waste that so many of the finer specimens of our race remain "bachelors," and fail to fulfil their natural obligations, when there are two millions more women in the country than men. Undoubtedly every bachelor over 30 should be heavily taxed according to his income, and this tax should be used for the benefit of parents producing large families of healthy children. It must be made easier for the best types of parents to bring up their children.

The Effect of Mentally Defective Children on Race Decay.

Time is pressing, or much ought to be said regarding the relation between defective and mentally deficient and feeble-minded persons and race deterioration. There are many weak-minded people of varying degree at large; they are a danger both to themselves and the State. Without sense of right and wrong, often ill-developed, they are a constant cause of anxiety. Weak-minded girls quite commonly bring illegitimate offspring into the world, and others marry, in both cases almost certainly reproducing and perpetuating the parents' lack of mental capacity.

The education authorities are gradually making provision for the training and comfort of afflicted children in their work. In addition, many blind and deaf children are maintained in various residential institutions, and others are taught in special day schools. Cripple children are treated and taught in residential schools. Mentally defective children are accommodated in special day schools, in which the training is directed towards learning some

useful occupation. *Epileptic children* are sent to epileptic colonies, where adequate provision is made for their school instruction.

But these are makeshift arrangements, chiefly the result of philanthropy, and admission to these institutions is quite optional on the part of the afflicted people, whereas in most cases it should be compulsory. There must be powers whereby such of these afflicted persons as cause danger to the State may be placed under *permanent restraint* in well-organized and supervised institutions, where they would be safe from harm themselves, and unable to inflict it upon others. Cannot our profession bring powerful influence to bear on this matter, and press for legislation?

Overcrowding and Housing and Town-planning Matters.

Overcrowding is answerable for much of our physical degeneracy, and our profession would do well to take a more active interest in the housing and town-planning questions in our larger towns. More than 77 per cent. of our population is now urban, and the same care evinced by the more advanced Continental countries in town planning has not hitherto been shown in this country. Reforms are urgently needed in the social conditions of the poorest of our fellow-citizens. It is impossible to have strong bodies, or fresh, joyful, clean minds, when the days and nights are spent in squalid streets, and overcrowded, gloomy, sunless, ill-ventilated, filthy houses, such as many of our poorer classes are compelled or content to dwell in. No wonder the low-class but brightly-lit public-house proves an attraction. No wonder there is a lack of discipline, self-respect, and patriotic feeling in a considerable class of the rising generation. Much is being done to remedy this deplorable state of things both in Manchester and elsewhere, but if there is to be any chance for a large town to have the conditions necessary for health and strength in all its districts, or even in only its new districts, it can only be attained by the active work of the whole profession in co-operation with our health medical officers, and with the various educating societies and persons who have been striving to enlighten the public, and to obtain compulsory powers to effect these objects. The local authorities, and even Parliament itself, must be constantly impressed with the nature of, and need for, conditions of health in our towns; and it is to be hoped that the more intelligent and public-spirited will succeed in interesting the ratepayers at large in the maintenance of the conditions essential for the health and strength of the whole community. If Mr. Burns's Town Planning Bill be passed next year, the town councils will be able to insist on the provision of playgrounds and other open spaces in all new districts and the limitation of the number of houses in a district; but the town councils are not likely to use their powers at all fully unless backed up by that public opinion which we as a profession, on a subject such as this, are so well qualified to form and influence.

Societies and Associations working at Social Reform.

The various health societies whose object is to improve the condition of the people should be supported by our profession. The Manchester and Salford Sanitary Association is the oldest of its kind in the country, and has had much to do with many of the reforms which have been effected here during the last half century. How many of us take any active part in its work? Here is a pleasant field of enterprise for any of our younger members willing to labour in the great cause of physical regeneration.

There are many other kindred societies, all of which deserve our cordial support.

The beneficial effects of living under the ideal conditions provided by garden cities are strikingly shown by statistics from three well-known places. At Letchworth the average death-rate per 1,000 is returned at 4.81 and the infantile mortality at 38.4 per 1,000; at Bournville the figures are 7.5 and 80.2; and at Port Sunlight 8.0 and 65.4 per 1,000.

What has been done in Sweden by Efforts to Regenerate.

One of the most encouraging facts with regard to the possibility of restoring the health and strength of a nation is to be seen in what has happened in Sweden. Seventy or eighty years ago the Swedes were fast becoming a degenerated race, but they appreciated their condition

before it was too late. They reformed their licensing system, planned their towns so as to secure much vegetation and ample open spaces, and gave the youth of the country a sound gymnastic training on the system which is now recognized to be the best. They are now the finest race in Europe, and, what is most remarkable, the men of the towns, owing to the excellence of the details that have been observed in their planning, are, as a rule, as robust and as strong as those of the country.

The Evil Effects of Impurity on Stamina.

How seldom the voice of our profession is heard in discussions concerning public morality and the remedies for checking impure habits and tendencies. These prevail in every section of society. They are all the more deadly because more secret, more insidious, more insinuating, more winked at, than any other vice. They are a cause of much immediate and future degeneracy. The strength of the race and its ability to hold its own depend very largely upon the ascendancy of the good over the bad, and the return of our people to a right moral standard. I would confidently submit that instruction ought to be given to boys and girls on sexual matters, preferably by their parents, but as this seems impossible amongst the poor, it should be done by the school medical officer. Parents are silent on this subject; it is wrapped up in an obscuring mystery, which only tends to arouse the curiosity of the child. The result is that the lessons regarding our common nature are learnt from strangers, servants, or erring and ignorant school companions. Boys and girls should be instructed on sexual matters before leaving home for school; their confidence should be invited on any point of difficulty; there should be a frankness and openness with them, so that their trust may be gained and their secrets revealed. We teach our children not to lie and not to thieve, both of which by nature they are prone to do, but regarding sexual feelings, difficulties, and sins, which as surely are natural to them, we are content to leave them in utter ignorance, without any guidance, prop, or safeguard. A tactful warning concerning the effect of bad habits on health, followed by lessons on self-restraint and the needs of others, and on the advantages of play and work, will do no harm, but will place them on their guard. "For if the youth be grafted straight and not awry, the whole commonwealth will flourish thereafter." Too great emphasis on these topics is of course to be avoided, or the very opposite effects to those aimed at may be produced, as for the attainment of the desired result love and faith on the part of the child are requisite. The prevailing notion that human passion cannot be repressed without harm is false. As practitioners of medicine we cannot be too insistent on this point, though from knowledge gained from patients it is to be feared that advice fraught with the gravest danger is sometimes given. In the classic clinical lectures by the late Sir James Paget occur the following words, which should be indelibly written in every practitioner's mind:

Many of your patients will ask you about sexual intercourse and expect you to prescribe fornication. I would just as soon prescribe theft and lying or anything else that God has forbidden. Chastity does no harm to mind or body; its discipline is excellent; marriage can be safely waited for, and amongst the many nervous and hypochondriacal patients who have talked to me about fornication I have never heard one say that he was better or happier for it.

Effect of Venereal Disease on the Decay of the Race.

Intimately connected with the subject of *natura*, deterioration is that of venereal disease, its prevention and cure. The prevalence of these diseases in their earlier stages is, to some extent, a gauge of the morality of the people; their ravages on men, women, and children subsequently are indications that effective treatment has not been adopted or carried out. Venereal disease is preventable; it is conceivable that it can be as surely stamped out as hydrophobia or plague, but this could only be effected with the assistance and whole-hearted co-operation of the profession, supported by the will of the people; but in adopting means to that end care ought to be taken that a definite deterioration of public morality is not involved. It is bad to have venereal disease, but it might be worse if it were escaped only by methods which rendered immorality safe and easy. Better far let us strive to eradicate it by effective

treatment on the one hand and by public education on the other, by the diffusion of the knowledge of what these diseases mean to the individual, the home, and the community, and how unnecessary it is to run the risk of acquiring them. The home, the school, the college, the church should be the media of this education. It is the prejudice against the frank discussion of these subjects, the unfortunate reserve and shyness that increase the difficulty. Venereal disease is much less prevalent in the army now than formerly. In 1860, for every 1,000 soldiers in the British army in the United Kingdom and India there were 1,053 admissions into hospital for venereal disease. In 1890 there were 196 admissions per 1,000 in the United Kingdom and 376 per 1,000 in India. In 1907 there were 71.9 admissions per 1,000 in the United Kingdom and 89.9 per 1,000 in India. This remarkable improvement is largely due to an increase in temperance in the army during recent years; but it is also due to better barrack accommodation, better clothing, better sanitation, more effective treatment. The army surgeon is more thorough, practical, and successful in his treatment of venereal diseases than is the civil doctor; it is, moreover, the custom for the former to deliver lectures to the troops under his charge on matters of personal hygiene, and concerning the dangers to himself and his country that a soldier incurs who practises illicit connexions. There are no statistics to prove, but there are ample reasons for believing, that there is no such striking decrease of venereal disease amongst our civil populations during recent years as has occurred in the army. It would be well if similar methods of diffusing knowledge could be adopted by civil practitioners.

It is interesting to note how foreign armies suffer in comparison from these diseases. In 1906 29.1 per 1,000 admissions took place in the French army, 18.8 in the German, and 158.91 in the United States army, whereas 68 per 1,000 admissions occurred in the United Kingdom. Thus in Germany and France, where legislation has provided for the supervision and examination of prostitutes, the number of admissions is three times less than in Great Britain and eight times less than in the United States. It is not, however, clear that this diminution in the disease is due so much to police supervision as to the methods of prophylaxis which are practised by German and French soldiers. In my experience the disease is so frequently spread by clandestine intercourse which no legal enactments would touch, that it is not to the official registration of prostitutes in certain towns for which the Contagious Diseases Act now repealed provided, that we can look with hope (for if legislation is to do any good it must apply to the whole community, and to men and women alike); nor is it to the notification of these disorders, which would only be an encouragement to "quacks," and hence to a greater inefficiency in treatment; but it is to the spread of information to men and women, youths and maidens, of all grades of society, about the prevalence and far-reaching consequences of such diseases; to the enforcing of the laws that already exist against solicitation in their application to both sexes, and in the provision of gratuitous treatment in general hospitals.

An international conference was held in Brussels in 1899 to consider prophylaxis in syphilis and other venereal diseases, and the foremost recommendation was a general dissemination of knowledge and information regarding the significance and prevention of these diseases—by giving instructional lectures to specially selected audiences, foremost of which should be university students, so that afterwards they could continue to spread sound knowledge on the subject.

With all respect, I would say that year by year more and more convincing facts come before me which prove that our medical schools are too sparing in their lessons on the treatment of venereal disease. The subject is regarded as a nasty one and not deserving much attention; there is no provision for the admission or treatment of these cases in the majority of general hospitals, from many of which they are excluded. And hence young practitioners are launched ill equipped to grapple with the difficult and interesting problems connected with these complaints, which have, perhaps, greater and more baneful influences on national health and upon fertility than any other diseases. Men are constantly passed as cured of gonorrhoea when still infective, and victims of syphilis

are assured of their immunity either because their symptoms have gone or because they plead to be told so. There is no royal road to the cure of these diseases, and the insistent appeals of the patient to be told he is cured and can marry must be resisted. It requires both tact and firmness to convince the patient of the necessity of and to carry out long-continued and effective treatment, but success can be attained. The happy results following the treatment of cases of syphilis under my care a quarter of a century ago, many of whom are now in happy homes, surrounded by healthy children, justify our assurance in the ultimate cure of all, except very exceptionally severe cases of syphilis, and amply repay any extra trouble that these cases often require. Twenty-two years ago I read a paper before this society entitled *The Evil Effects of Imperfectly Treated Early Syphilis*, and later experience has more than justified the conclusions that were advanced on that occasion. Imperfect treatment means increasing physical deterioration, an enormous loss of health, and a considerable mortality to the country—a mortality infinitely greater than statistics show, because, as you know, the reports of the Registrar-General by no means give an accurate statement of the number of deaths due to syphilis in this country.

There are gross men of repulsive habits who come before us with these diseases for whom little or no sympathy can be aroused; but oftener it is the young man or girl with the saddest history towards whom our hearts go out in boundless sympathy. The fitting of such as these to take their place again in life is no inglorious task, for although marriage must often be long delayed, it can take place with safety and with assurance.

Effect of Universal Military Service on the Stamina of the Race.

Before concluding, attention must be called to the immense advantage that would accrue to the health and stamina of the race if a system of universal military training were enforced. This is necessary for national security and independence, both of which in the last resort depend upon the possession of adequate power to resist hostile attack. It is desirable also from the point of view of national health, and national character. There must be something wrong with the "tone" and the sense of justice and righteousness of a nation, when, out of the millions available, it is impossible to find a paltry 300,000 men willing to undergo the limited amount of training in the Territorial Force that is considered necessary to enable them to take an effective part in the defence of their homes and country. The medical profession has responded splendidly to the call—but the majority of the men of the nation hold back. What a contrast there is between the "prating" and "screaming" about the glory of the British Empire, between the "jingoism" of Mafeking Day, and the abject appeals to be seen in the press every day to induce men to join the Territorial Army, which, though in existence a year, is little more than half its authorized strength. In this public apathy to the well-being of the country, in this indifference to national honour, is a latent sign of decay and degeneracy. The existence of a State depends upon the willingness of its citizens to prepare themselves for its defence.

In the days of Roman greatness, before signs of degeneracy appeared, every Roman was a soldier and every soldier was a citizen. It has been so in England, and when it was so the name of England was never more respected and feared abroad, nor, considering the period, were the liberties of Englishmen ever more secure than when every able-bodied man in England was trained to the use of arms and thus prepared to effectually defend his country from the enemy at her gates.

On every side we hear objections to *compulsion*, and to the cost that its adoption would entail. The estimates for the latter are grossly exaggerated, and compulsion is unfortunately necessary in many less important walks of national life. That its adoption would be likely to plunge our country rashly into war is absurd. If every man were both soldier and citizen, liable himself to be called out in case of need, no Government or nation would lightly incur such a grave responsibility. Untrained men talk glibly of the martial attitude they would assume should hostile invasion ever occur, forgetful or ignorant of the disastrous consequences that would result if as civilians they implicated themselves in any act of war. Owing to our insular position, many of the horrors of war have long

forgotten by the English people. It can be inferred, however, what would happen to our civil subjects, if foreign soldiers landed on our shore, by the behaviour of the German army to a hostile French civil population during the Franco-German war. No mercy was shown, but plunder, pillage, summary executions, burning of villages—in fact, the severest form of punishment was accorded, not only to civil offenders themselves, but whole communities were held responsible for individual actions.

The men who are so insistent on the necessity for compulsory training are not "alarmists," but calm, cautious, level-headed, experienced men, many of them England's most trusted sons. What is it they ask? It is simply this: that *all* our fellow-countrymen, physically fit, between the ages of 18 and 25, should be made to undergo four months' continuous military service, and subsequently to serve for four years in the Territorial Force, during which latter period two weeks' camp training only in each year would be necessary. What could be better for the physique and *morale* of the nation than this? It is proposed that the training should take place under canvas, not in barracks; that each man should be developed to his best by suitable exercise, food, and clothing; that he should be taught to shoot, to march, to ride; to think and act independently; to yield ready and implicit obedience to orders; to practise self-respect and good comradeship. During this time also each man would be under the care of a good doctor, specially trained, to look out for and correct the weaknesses which cause deterioration. A training such as this would have a striking influence on every class. "Duke's son and cook's son," by more intimate acquaintance, would learn a higher respect for each other. Our industries would flourish, because men engaged in them would be trained in habits of obedience, self-respect, and precision. "Overcrowding" and "our slums" would soon be gone, because, as a result of a couple of generations' training of our male population in the open air, a sounder public opinion would result, strong enough to enable our municipal authorities to remedy these crying evils.

I have watched over and over again the effect upon recruits of their first three months' service with the colours. It has been marvellous. The lank, ungainly, casual ill-developed loafer becomes an alert, strong, intelligent, orderly, self-respecting man. The good effect of even two weeks' training in camp on general health and physique is known to many of you. What would be the effect upon the character, the manliness, the physique, the patriotism of the nation if every able-bodied young man was compelled to train for the safety of his country in the open air for four months? England's sons now are of the same race as their heroic forefathers. The same blood runs in their veins as that which flowed on many a battlefield in the earlier days of Britain's history. The greatness of our country and its immense reserve of power is not denied. Will our sons prepare themselves to defend it or wait for defeat (which would mean destruction as a nation) to awaken them from lethargy? Cannot we influence the nation on the importance of this training, not only as necessary for maintaining the place and honour of Britain amongst other nations, but as essential for the improvement of our national health?

The vital question only remains: Can we as a profession take concerted practical steps to stem decay among our fellow countrymen on the one hand and to foster sound racial development on the other?

While sociologists discuss, the canker grows. While medicine works some triumphs, deterioration is spreading far and wide.

Must degeneration necessarily increase? Is our race so exhausted by the excitement and overstrain of the last few generations that she cannot recover? No; she can and will do so, as soon as the enlightenment of every class is seriously undertaken.

A lofty estimate of family life must be restored as a foundation for the re-establishment of our national life and strength.

In such an effort our part should be no ignoble one. The issue of a battle depends not alone on the intelligence of the commander, but to some extent upon the weapons he employs. In the great campaign against decay the profession of medicine should be one of the most formidable weapons. Her members have unequalled

privileges. They penetrate the closed door; they are the recipients of the secrets of many a forlorn and stricken heart. Their voices find thoughtful listeners, not only in the councils of the wise, but among those whose perplexed and troubled minds would be deaf to any other guidance.

Do we shrink from the task, because we are not invited to undertake it, because the public do not realize the danger, because the exigencies of life are such that we have neither leisure nor means to fight in the battle; or *are we afraid?* I think not. Once convinced that the work must be done, our profession will be true to her traditions and resolutely wage war against ignorance and vice, giving no thought to public estimate or gain. Nay, her members will, with inexhaustible faith in the power to right much that is wrong, join heartily with those already in the field, those who have thrown their influence and their service into the scales, so that by the weight of combined opinion and by strenuous effort the balance will be found on the side of such judicious thought and fearless action as shall eventually bring about a greater and more lasting strength in our national life, health, and habits.

May I sum up my simple reflections in a sentence? He does a great deed who heals the sick; but the watchful physician who inculcates sound habits amongst a people performs a nobler task.

A Lecture

ON

FISTULA BETWEEN THE STOMACH AND BILE PASSAGES.

WITH REMARKS ON OTHER INTERNAL BILIARY
FISTULAE.

DELIVERED BEFORE THE LONDON MEDICAL GRADUATES'
COLLEGE AND POLYCLINIC.

By A. W. MAYO ROBSON, D.Sc. F.R.C.S.

My reason for selecting this subject was a remark recently made by a medical friend at a consultation we held on a case of biliary fistula communicating freely with the stomach. When I told him that his was the fifth case of biliary gastric fistula that I had personally seen, he asked me why I had not reported the cases, seeing that the literature on the subject in the ordinary textbooks was so meagre that he had been unable to get any trustworthy information on it. As a matter of fact, however, there is a chapter on fistulae in my work on *Diseases of the Gall Bladder and Bile Ducts*, though it does not deal specially with fistula between the stomach and biliary passages.

Fistulae communicating with the surface, or so-called external fistulae, are so obvious that no skill is needed in their diagnosis, but the same cannot be said of the internal or intersisceral fistulae, which, though far from uncommon, are often exceedingly difficult, or at times even impossible, to diagnose. Though they may result from the progress and breaking-down of a malignant growth, from ulceration of the stomach, duodenum, or colon, or from hydatid disease, yet the most frequent cause of internal biliary fistulae is gall stones. It is not my purpose in this lecture to consider the question of external fistulae, or of internal fistulae due to growth, but to give some of my experiences of those occurring between the biliary channels and the gastro-intestinal canal.

The channel of a fistula may be either direct, in which the two organs immediately communicate, or indirect, owing to an abscess having formed and burst into contiguous hollow viscera, which then communicate indirectly through the abscess cavity.

The former, or direct fistulae, are for the most part due to gall stones producing ulceration in the gall bladder or bile ducts, and as the ulceration advances towards the peritoneal surface a local peritonitis ensues and causes adhesions to a neighbouring hollow viscus. The ulceration continuing, a communication is established between the two channels.

Although the formation of an internal fistula is at times

dangerous from perforation, or from extension of inflammation, in some cases it effects a cure by allowing the gall stones to escape into the intestinal canal and so to be passed. In other cases, the gall stones after passing into the intestines may set up secondary troubles—for instance, when they have passed into the intestine, intestinal obstruction; when into the stomach, violent vomiting; when into the kidney, symptoms resembling those of renal calculus.

In one of my cases a gall stone lodged in the ileum and formed the centre of a tuberculous deposit leading to a stricture, which I was able to treat by excising about 18 in. of the small intestine. The patient was well some years later.

Many internal fistulae, as will be seen by the appended classification, are mere pathological curiosities, quite undiagnosable, and only capable of being discovered at the time of operation or at necropsy.

Many must form and heal, leaving the patient cured, and thus not only are they undiscovered, but they are probably not even suspected; for, contrary to what one might suppose, fistulae between the bile passages and other hollow viscera in the majority of cases heal spontaneously, leaving only firm visceral adhesions; this accounts for the fact that internal biliary fistulae are comparatively seldom found *post mortem*.

Out of 10,866 necropsies made by Roth, Schroeder, and Schlotz, 43 biliary fistulae were found: 1 between the gall bladder and stomach, 19 between the gall bladder and duodenum, 16 between the gall bladder and colon, 5 between the common bile duct and duodenum, 1 between the biliary passages themselves, and 1 between the gall bladder and liver.

I do not think that any complete collection of all the published cases of fistulae has been made since the work of Courvoisier and Nannyn, but even that can only give a very imperfect estimate of their frequency, for the reasons I have stated.

Usually the ulceration leading to fistula proceeds quietly and painlessly, producing very few symptoms until, it may be, a gall stone sets up obstruction in its passage down the intestinal canal; or, after the formation of a fistula, all the symptoms pass away and the patient makes a complete recovery. If, however, other gall stones have been present and have not escaped through the fistula, but passed into the cystic or common ducts, the symptoms are likely to recur when the fistula contracts, as in the following case:

CASE I.

History.

Mr. L., aged 50, had been subject to painful attacks called indigestion from the age of 14 to 16, but he had been free from seizures for eighteen years—that is, until sixteen years ago, when acute pain was felt, followed by jaundice and associated with fevers and rigors. Since that time he had had similar attacks at varying intervals, but lately there had been rigors, continued fever, and increase of jaundice. When seen by me the liver was 1½ in. below the costal margin, but no tenderness could be detected anywhere. A slight icteric tinge was present in the conjunctivae. The attacks appeared to have been brought on by gastro-duodenal catarrh extending to the

common bile duct and to the pancreas. A diagnosis of gall stones in the common duct was made and an operation advised.

Operation.

On January 29th, 1905, the gall bladder was found firmly adherent to the surrounding structures, and was separated with difficulty. A fistula between the gall bladder and the duodenum was thus exposed, and after separating the gall bladder, the opening in the duodenum was closed by a purse-string suture. Two stones were felt in the pancreatic portion of the common duct, and there was also some swelling of the head of the pancreas. The stones in the duct were extracted by the scoop after incising the duct. No more stones could be detected in the ducts, and a probe readily passed down into the duodenum. The gall bladder was small and contracted, and the cystic duct was strictured at the junction with the common duct.

Cholecystectomy was performed, and the hepatic duct was drained by a tube passing through the incision in the duct, which was closed around it by a catgut suture. A gauze drain was passed down by the side of the tube and the wound closed. The patient made a good recovery, and is now well.

The sequence of events in this case clearly pointed to gall stones, then to the escape of some by ulceration. So long as the fistula remained freely patent, there was an absence of symptoms, as there was no back pressure in the bile ducts, but as soon as the fistula narrowed the gall-stone troubles returned.

CASE II.

History.

A similar sequence of events occurred in another case that I saw in September, 1903, where there was also a twenty years' history of gall stones, though during the previous four years the attacks had been more frequent, and for nine months there had been slight jaundice with symptoms of infective cholangitis.

Operation.

In this case not only was there found a fistula between the gall bladder and duodenum that had resulted from the ulceration of a gall stone into the duodenum many years previously, but there were also gall stones in the gall bladder and in the common duct. So long as the fistula was freely open, the patient had been free from jaundice, but as soon as the fistula contracted—for at the time it had become very small and would no longer allow the bile to escape—jaundice supervened, and the damming back of infected bile into the bile ducts was the cause of the infective cholangitis. The removal of the gall bladder and calculi, the closure of the opening in the duodenum, and drainage of the bile ducts resulted in complete and permanent recovery.

But the presence of gall stones is not necessary for a recurrence of the pain, as in the following case:

CASE III.

Miss H., aged 55, seen on November 23rd, 1904, on account of attacks of pain in the region of the gall bladder, which had been continuing off and on for ten years.

History.

The patient gave a history that about twenty years previously she had been very seriously ill with intestinal obstruction, and had passed some large gall stones, which fortunately had been retained, and which she showed me. For ten years she was well. She said that then she began to again suffer from occasional attacks of pain in the gall bladder region, which attacks had recently become more and more severe, though they were never accompanied by jaundice.

Operation.

On December 1st, 1904, I removed a contracted gall bladder, in which a cavity that would hold a large pea was communicating with the duodenum by a very minute channel that would only admit a No. 1 catheter. The cystic duct was completely strictured. After the removal of the gall bladder and closure of the duodenal opening she made a complete and satisfactory recovery.

The case is interesting from the fact that the gall stones had evidently ulcerated their way into the duodenum twenty years before my seeing her, that so long as the fistula was widely patent no trouble was experienced, but, as soon as the fistula began to contract, mucus collecting in the remains of the gall bladder gave pain in its passage into the bowel along the fistula, as the contents of the gall bladder could not escape into the common duct on account of stricture of the cystic duct.

Symptoms of Formation of Fistula.

Although the ulceration may at times occur quietly and without any serious disturbance to health, it is not always accomplished without symptoms, such as pain beneath the right costal margin, more or less continuous fever of an irregular type, possibly associated with rigors and other symptoms pointing to infection. On examination there will be found rigidity of the right rectus, distension of the

upper abdomen, owing to paresis of the stomach and colon, and possibly the presence of a tumour due to matted omentum and swollen and adherent viscera.

Haemorrhage into the stomach or intestines may occur from ulceration into a large vessel while the fistula is forming, or subsequently, and in one case reported to me by a friend the haematemesis proved fatal.

If the fistula occurs between the stomach and the gall bladder the stones may be vomited, as in two cases I have seen; but it does not follow that vomited gall stones come from a gall-bladder-stomach fistula, as in one reported case the patient died after the vomiting of gall stones, and at the necropsy a fistula was found between the cystic duct and the duodenum.

If the gall stone is of large size, as in a case that I will relate, it may remain in the stomach, producing great irritation with vomiting, and leading to symptoms of intestinal obstruction.

If the fistula is between the gall bladder and the duodenum (the most common variety), the whole length of the intestinal canal has to be traversed by the concretions, hence such cases are found to be more frequently associated with intestinal obstruction than when the fistula occurs between the gall bladder and the colon, for in the latter case the passage to the anus is usually accomplished without difficulty, though occasionally the concretions may lodge and cause trouble.

When a gall stone is impacted in the common duct just before entering the duodenum or in the ampulla of Vater, ulceration of the orifice of the duct is apt to occur, allowing the concretion to escape into the duodenum by an enlargement of the orifice of the papilla. There is also the possibility of a direct fistula developing between the common duct and the duodenum, instead of ulceration of the ampulla. Such gall stones are of moderate size, seldom larger than a filbert, and rarely give rise to any other trouble in passing through the intestine.

Intestinal Obstruction due to Gall Stones.

It must not be assumed that all cases of intestinal obstruction due to gall stones are dependent on gall stones ulcerating through the walls of the biliary tracts, though this is the ordinary explanation.

By intestinal obstruction from gall stones is usually understood the impaction of a large concretion in some part of the small intestine producing a mechanical block; but this is only one of the several varieties of obstruction of the intestines dependent on cholelithiasis. There are clearly four classes of obstruction depending essentially on gall stones:

1. Acute obstruction caused by local peritonitis in the region of the gall bladder leading to paralysis of the bowel. Of this variety I have seen several examples, all of which recovered without operation.

2. Volvulus of the small intestine, dependent either on the violence of the colic caused by the attack of gall stones or on the contortions induced by the passage of a large concretion through the small intestine. In two cases of this kind operation was performed, recovery following in each after simply untwisting the volvulus.

3. Mechanical obstruction due to the passage of a large concretion through the small intestine.

4. Obstruction coming on after the original cause has disappeared, and depending on adhesions left by local peritonitis due to gall-stone attacks, or on narrowing caused by the healing of a fistulous opening through which a large gall stone has made its way into the intestinal tract.

Gall-bladder-duodenal fistulae are not at all uncommon. I have operated on eight. There are a number of good specimens in the various pathological museums, for instance:

No. 2326, Royal College of Surgeons Museum, shows a gall stone in the act of extrusion, and it will be seen that the margins of the opening are ulcerating to allow of the passage. Death occurred after six weeks of suffering.

Specimens Nos. 2327 and 2328 in the same museum are also good examples.

No. 1399 in Guy's Museum shows a gall-bladder-duodenal fistula 1 in. from the pylorus, large enough to admit the finger; and 33 in. above the ileo-caecal valve is a large gall stone impacted in the ileum.

Nos. 2261 and 2262 in St. Bartholomew's Museum show gall-bladder-duodenal fistulae.

No. 1676 in King's College Museum shows a gall-bladder-duodenal fistula. Death occurred from peritonitis, though the gall stone had passed per anum.

No. 1595 in the Middlesex Museum shows a gall-bladder-duodenal fistula, through which gall stones passed. Death occurred from intestinal obstruction.

Specimens of gall-bladder-colic fistulae are much less common than duodenal fistulae, probably because they do not often cause death. I have operated on four. There are, however, a sufficient number of examples to show that even this method of passing gall stones is not altogether a safe one.

CASE IV.—Gall-Bladder-Colic Fistula.

Mr. G., aged 50, seen with Dr. W.

History.

There was no history of spasms; the first attack of gall-stone colic occurred in October, 1897, followed by jaundice; severe seizures in December, 1897, with jaundice lasting two months and associated with ague-like seizures; slight attacks for a year, and then one very severe in December, 1898, and again in January, 1899. During the whole of the period the icterus deepened after each attack, and occasionally rigors occurred—lost over a stone in weight; jaundiced, but not deeply; liver not enlarged; no tumour of the gall bladder; tenderness above and to the right of the umbilicus; well-marked dilatation of the stomach.

Operation.

January 28th, 1900, Fistula between shrunken gall bladder and colon discovered; cystic duct shrunken; common duct dilated to size of small intestine, and containing large floating gall stone. After excising the gall bladder an incision was continued down the shrunken cystic duct until it reached the dilated common duct; a gall stone was crushed in removing it and the fragments were removed; tube introduced into common duct; fistulous opening into colon closed.

The patient made an uninterrupted recovery and remained well for six years.

As showing the importance of recognizing the presence of even a small fistula when separating adhesions, I had the experience some years ago of missing a minute fistula into the colon when separating very dense visceral adhesions, the result being escape of the visceral contents and peritonitis.

Biliary gastric fistula is apparently less common than one might expect, seeing that the pylorus is not infrequently fixed to the gall bladder by adhesions. The following is the description of a chronic case:

CASE V.—Biliary Gastric Fistula.

A lady, aged 60, suffered from constant dyspepsia, with frequent vomiting and steady loss of flesh.

Operation.

The stomach was found firmly adherent to the gall bladder, and on separating adhesions a fistula between the gall bladder and stomach was found. The edges of the fistula in the stomach were pared and the opening closed with two rows of sutures, while the opening in the gall bladder was utilized for removal of the gall stones and afterwards for drainage. The patient made an excellent recovery, and is now in good health.

In this case the discharge of septic bile into the stomach proved a constant source of trouble, leading to nausea and vomiting and giving rise to chronic septic absorption and a suspicion of malignancy.

The proposal, therefore, in obstructed common duct to drain the bile passages into the stomach seems to me undesirable.

CASE VI.—Gall-Bladder-Gastric Fistula Operated on in the

Acute Stage.

On the evening of October 29th, 1906, I was asked by a surgical friend to see an urgent case with him about ten miles from town, the patient, a gentleman of 76, being very ill, with symptoms of acute intestinal obstruction.

History.

He gave a history of having been perfectly well up to October 26th, on which morning he went out for a walk. Later in the day he was suddenly seized with acute pain in the upper part of the abdomen, slightly to the right side, and almost immediately began to vomit, first the contents of the stomach and afterwards mucus and any fluid that he took. The vomiting was repeated frequently, but at no time did it contain bile. The abdomen became somewhat distended, though more markedly at the upper part. Acute intestinal obstruction was diagnosed, and all food by the mouth was stopped, as even a little fluid was rejected, and the patient was fed only by nutrient enemata. On October 29th the vomiting continued, and the nutrient injections could not be retained.

When I saw him on October 29th I found the abdomen somewhat, though not enormously, distended, and a distinct, hard swelling could be felt beneath the right costal margin. The stomach was dilated and the ascending colon and caecum were

also manifestly more distended than the descending colon. Examination by the rectum showed well-marked ballooning. The urine was scanty but contained no albumen. The tongue was dry and the pulse quick, but the temperature was only a little above normal. There had never been any symptoms of gall stones, nor had he been specially troubled with constipation up to the onset of the acute seizure. The bowels were slightly moved as the result of an enema on Sunday and a little flatus was passed on Monday, but no decided relief resulted.

A diagnosis was made of obstruction at the pylorus and also at the hepatic flexure of the colon, the cause being probably a growth in the region of the gall bladder involving at the same time the stomach and bowel. The possibility of a gall stone ulcerating into the bowel was considered, but not thought to be probable, as there had never been any history whatever of gall-stone attacks in the past. An operation was proposed, but for family reasons could not be carried out until the following morning.

Operation.

On opening the abdomen the stomach and hepatic flexure of the colon were found firmly fixed to the under surface of the liver, and beneath them could be felt a hard swelling. On palpating the stomach a hard lump the size of a small hen's egg could be felt in it, and as this could be freely moved in the stomach cavity it was evidently a concretion.

It at once became clear that the patient had been suffering from cholecystitis due to gall stones, that one had ulcerated through into the stomach, and that another was probably ulcerating into the colon. After packing off the abdominal cavity by sterilized gauze, the stomach and colon were rapidly separated from the under surface of the liver and gall bladder, the pus and mucus which escaped being mopped up by gauze swabs. A fistula was exposed passing between the gall bladder and pylorus of the stomach, the other was found between the gall bladder and colon. Through the former the large gall stone had passed into the stomach; in the latter the smaller gall stone was impacted, it not yet having effected its escape. The opening into the stomach had to be extended a little in the direction of the pylorus before the gall stone could be extracted, after which the stomach opening was closed by stretching open the sides of the fistula so as to bring the edges together, trans- versely to the pylorus, as in pyloroplasty. A No. 1 chromicized catgut suture was employed to bring the edges of the fistula together, and a Pagenstecher's suture brought together the serous surface. Attention was next directed to the opening in the colon, which was closed by a purse-string suture, after which the gall bladder was excised and the cystic duct ligatured beyond another small gall stone which was impacted in it.

After purification of the region of operation, the right kidney pouch was drained by a strip of gauze enclosed in an india-rubber tube and brought through a stab opening at the most dependent part. The abdominal wound was then closed by a continuous catgut suture, uniting the peritoneum and posterior aponeurosis, it being continued back along the anterior aponeurosis and sheath of the rectus, the union of the wound being strengthened by three silk-worm gut sutures transfixing all the layers of the abdominal wall. The skin edges were brought together by Michel's clips. Five minims of strychnine were given subcutaneously, and a pint of saline with an ounce of brandy was administered by rectum and repeated in two hours.

After-History.

The operation, which occupied about half an hour, was completed with the patient in good condition. After the operation he had no further sickness, and the pulse during the next day did not exceed 100, nor was the temperature above normal. Flatus was passed on the second day, and the patient took plenty of fluid nourishment.

On November 2nd the pulse became more rapid and slight delirium was reported. From this time, although the wound progressed satisfactorily, he became excited and restless, and for some time his mental condition gave rise to concern, but eventually, as he got stronger, the mind completely cleared, and at the present time he is in perfect health both physically and mentally.

The measurement of the largest calculus removed from the stomach was 3½ by 3 cm. in diameter, and that of the smaller one 2.3 cm. by 2.5 cm. The smallest crumbled after removal.

CASE VII.

Last year I was asked to see a very interesting case by an eminent surgeon who had removed gall stones from the common duct, and at the same time he had had to remove the gall bladder which was the site of phlegmonous cholecystitis. Silk ligatures had been employed, as is the custom I find with a number of surgeons. A biliary fistula followed, and after a time the fistula began to discharge some of the stomach contents very shortly after food or fluid had been taken. My explanation of the case was that a silk ligature had ulcerated its way from the biliary passages into the stomach, and that probably the fistula would close if the tube was left out, as from the small amount of bile that had been discharged all along it was quite clear to me that there was no permanent obstruction of the common bile duct.

I was gratified to learn a few weeks later that the patient was quite well, and that within a week of leaving out the tube the fistula had permanently closed.

I cannot but think that the use of silk ligatures at any operation on the biliary passages is fraught with risk of

subsequent trouble, as it is universally recognized that in nearly every case where gall stones are present the bile contains septic organisms. Thus, if silk is used, it is likely to become infected, and so form an infected centre until it is discharged; moreover, an ample experience of the use of carefully prepared iodized catgut has convinced me that it is both safe and efficient, lasting a sufficient time in the tissues to effect its purpose, but not remaining longer than necessary.

On two occasions in which I have operated for disease of the gall bladder I have found it distended with gas; this unusual phenomenon was in both cases dependent on a fistula between the intestinal canal and the gall bladder. I will give brief notes of one case.

CASE VIII.—Gall Bladder Distended with Gas.

On October 10th, 1906, I was asked to see a lady aged 59.

History.

In 1899, after years of suffering from abdominal pain, she had passed several large gall stones. Relief followed, but she never completely regained her health, and six months before I saw her she began to have pain in the upper abdomen, with partial obstruction of the bowels. The pain, which was paroxysmal, was followed by rigors, but without jaundice. There was marked tenderness and some swelling below the right costal margin, and distinct rigidity of the right rectus. Though there was a tumour to be felt on palpation, it was resonant on percussion. A diagnosis was made of cholecystitis with ulceration, and it was suggested that there might be a fistula between the gall bladder and bowel, through which infection had passed to the gall bladder, setting up chronic septicaemia. At the operation very firm adhesions were found binding the viscera together below the liver. The gall bladder had thickened walls, and it was distended with gas, there being a communication between it and the duodenum. Cholecystectomy was performed, and the wound in the duodenum was closed by a purse-string suture. The patient made a good recovery, and when heard of some time later was in good health.

On several occasions I have had the good fortune to catch gall stones in the act of forming fistulae. In one case I found a gall stone half extruded through an ulcerated opening into the peritoneal cavity. Had operation been delayed a fatal peritonitis must have ensued, as the distal extremity of the concretion was free in the peritoneal cavity and was firmly plugging the opening, behind it being a gall bladder distended with mucus. The patient, a middle-aged man, recovered after cholecystectomy, and was living some years later. In one case I found a gall stone ulcerating into the colon and plugging the opening between the gall bladder and the colon.

Double fistulae are occasionally found. I have related one case in which a gall-bladder-gastric and a gall-bladder-colic fistula existed in the same individual, and others have been recorded where at the same time fistulae between the various parts of the biliary passages and the duodenum and colon have been found.

The fistulae I have thus far mentioned have all had their origin in the bile passages, but I have also had experience of intervisceral biliary fistulae in which the origins have been from without the bile tracts—for instance, in cancer of the colon and stomach, and in hydatids of the liver bursting into the gall bladder and bile ducts—producing symptoms resembling in every way those of cholelithiasis.

I have also known ulcer of the duodenum and ulcer of the pylorus to perforate into the bile passages.

In the time at my disposal it is impossible to cover the whole of the ground; for instance, it would be interesting to relate examples of communications between the urinary tract and the bile passages, of which a number have been reported; in some of them gall stones had been passed by the urethra, and in others crushed in the bladder by the lithotrite or removed by lithotomy. Gall stones may enter the urinary tract either by direct ulceration into the pelvis of the kidney, or through a track extending along the round ligament to the umbilicus and then along a patent urachus, as in a case described and operated on by Krönlein.

Fistulae between the bile passages and genitals are also interesting, as, for instance, between the gall bladder and pregnant uterus, or between the gall bladder and an ovarian cyst, or between the bile passages and vagina, all of which examples have been recorded in literature.

BRITISH MEDICAL JOURNAL

Again, fistulae have occurred between the common or hepatic duct and the portal vein; four such cases have been recorded. I have on several occasions seen and operated on communications between cavities in the liver and the pancreas and the bile ducts, the communication being through a fistula established by ulceration.

Nor will time permit me to describe, except briefly, that interesting class of cases in which communications have been established between the bile tracts and the thoracic organs, the pericardium, the pleura and lungs.

Courvoisier collected 24 such cases of fistula between the biliary tracts, pleura and lung. Very few have been submitted to operation. I had a very interesting case of this kind sent to me from South Africa in May, 1903, of which the following are brief notes:

CASE IX. History.

Mr. G., aged 28, was quite well up to April, 1894, when he had an illness accompanied by a cough, and on the third day he began to expectorate; shortly afterwards he coughed up a large quantity of pus and bile. Before this attack he had had no liver symptoms, except that on one occasion he had had pain in the gall-bladder region, which, it was surmised, might be due to gall stones. Since that time, for the period of nine years, he had regularly coughed up bile and pus. At first he was thought to be suffering from phthisis, especially as he lost flesh rapidly and had night sweats. During the year before coming to England he thinks he did not get thinner, though the amount expectorated did not lessen. When I saw him he was round-shouldered and old-looking, as if worn down by illness, and his fingers showed marked clubbing. An examination of the chest showed no positive sign of lung disease, though some breath sounds were diminished on the right side up to the level of the seventh rib. The liver was decidedly enlarged but not tender, and projected 3 in. below the costal margin. There was slight jaundice. From 1 to 1½ pints of extremely offensive bile and pus were coughed up in the twenty-four hours. The pus was crowded with bacteria but did not contain tubercle bacilli or elastic fibres, and was manifestly not from a bronchiectasis.

Operation.

Operation was performed on May 21st, 1903. No cyst or abscess cavity was discovered in the liver, which was enlarged, and showed signs of cirrhosis. After numerous firm adhesions between the shrunken gall bladder and the under surface of the liver, and the stomach, duodenum, and colon had been separated, a gall stone the size of a small nut was found impacted in the hepatic duct, and removed through an incision in the duct; numerous adhesions fixed the back and the dome of the liver to the diaphragm. Drainage of the hepatic duct was effected by a rubber catheter, and a gauze drain was passed through a split rubber tube to the neighbourhood of the incised duct. The expectoration of bile was immediately arrested but offensive pus continued to be coughed up. The expectoration of bile returned on the third day and then gradually lessened; the cough also gradually became less, and the purulent expectoration rapidly diminished. The wound healed by first intention except where the tube had been, this healing by granulation.

After-History.

Two months later the patient had improved very much, was gaining weight rapidly, and was only coughing up a small quantity of mucus-pus without any bile. There was no jaundice, and all the bile was passing into the bowel. The wound had been soundly healed for a month, and he had been able to walk several miles a day. He returned to South Africa in the third month, and has since reported himself well.

Mr. Rigby also reported an interesting case in the BRITISH MEDICAL JOURNAL of August 8th, 1903, which was dependent on impacted gall stones and cured by cholecystectomy. Out of 18 autopsies collected by Courvoisier, 10 were due to gall stones, 6 to hydatids, and 2 to ascariides. It may, however, also be due to tropical abscess or to abscess of the liver from other causes.

CONCLUSION.

It may be asked what purpose can be served by relating a large series of unusual cases. Quite apart from the interest attached to these cases, to the difficulty of diagnosis, and the possibility of their cure by operation, I should like to dwell on the fact I have so often mentioned before as to the serious responsibility of allowing gall-stone disease to pass on until complications such as those I have mentioned have supervened, since operation for cholelithiasis at a time before the gall bladder and bile ducts have become seriously damaged, and the neighbouring organs have participated in the trouble, is almost devoid of danger if the operation be performed by an experienced and careful surgeon; whereas, if operation is only done after the parts have become matted together, after fistulae have formed and the patient is run down by fever and other septic complications, the mortality will be greatly increased.

AN UNUSUAL CASE OF APPENDIX ABSCESS DUE TO THE PNEUMOCOCCUS AND BACILLUS COLI COMMUNIS.

TREATMENT BY DOUBLE VACCINE: RECOVERY.

By EDWARD HARRISON, M.A., M.D., F.R.C.S.,

HONORARY SURGEON TO THE HULL ROYAL INFIRMARY.

WITH OPSONIC ESTIMATIONS AND VACCINE TREATMENT.

By EDWARD TURTON, B.Sc., M.D., M.R.C.P.,

HONORARY PHYSICIAN TO THE HULL ROYAL INFIRMARY.

THE case seems worthy of record not only on account of the unusually serious surgical conditions which had to be dealt with, but because distinct benefit appeared to be derived from the vaccine treatment during the time that the patient was so desperately ill from toxæmia. It would appear also that, as has been frequently insisted on by one of us (E. T.), in order to effect most good by bacterial vaccines, it is advisable to use a vaccine prepared from the organisms isolated from the patient's own pathological discharge, even if, as in this case, separation of the organisms is by no means an easy task.

S. H., a woman aged 27, was admitted to the Hull Royal Infirmary on June 10th, 1908, under the care of Dr. Turton.

History.

She had been ill for three weeks, with abdominal pain, general malaise, and headache. A week before admission the pain had become more intense, and was accompanied with vomiting, which persisted until admission, but was said never to have been faecal. The bowels had been open quite regularly, and there had been no diarrhoea. There was no history of previous attacks of pain, and menstruation had been regular.

Condition on Admission.

The patient was obviously very ill; her expression was anxious and her complexion earthy. The pulse was 130 per minute and very feeble, tongue dirty and dry, and respirations 24 per minute. She complained of pain all over the lower part of the abdomen, which moved slightly on respiration. Palpation of the abdomen was difficult on account of the large amount of abdominal fat; a large mass could, however, be felt below the umbilicus somewhat to the right of the middle line. It was dull on percussion, tender, and appeared to be freely movable. Nothing definite could be made out vaginally or per rectum. A provisional diagnosis of ovarian cyst, with twisted pedicle, was made by Dr. Turton and immediate operation advised.

First Operation (by Dr. Harrison).

Chloroform being administered, the abdomen was opened by an incision in the middle line, the incision being a somewhat lengthy one, on account of about 5 in. of fat which had to be cut through. On opening the peritoneum, a large mass was seen occupying the right iliac fossa and pelvis, and an effort was made to free it from the coils of intestine which were extensively adherent to it. The patient was placed in the Trendelenburg position and the upper abdomen packed off. An attempt was then made to isolate the mass by separating the adhesions, and it was seen that the greater part of the tumour was made up of matted mesentery. On working down in the pelvis, a gush of offensive pus was observed; this was mopped out and the patient placed in the horizontal position again. Owing to the great thickness of the abdominal parietes, it was now necessary to make an additional transverse incision dividing the right rectus. On further separation of the coils of the small intestine, the caecum was found in the abscess, with the stump of a ruptured and gangrenous appendix. This was removed, and, together with some pus and a soiled swab, was placed in a sterile tube for bacteriological examination by Dr. Turton. Drainage tubes were passed into the pouch of Douglas and the wound closed. On recovering from the anæsthetic, the patient, who was in a precarious condition, was placed in the Fowler position.

Progress.

The patient remained in an extremely critical condition for several days after the operation; the pulse was rapid and very feeble, and there was evidently severe toxæmia, although there appeared to be free drainage from the tubes. The result of the bacteriological examination had been to show the presence in the pus of the pneumococcus and *Bacillus coli communis*, and the opsonic index was estimated the day after operation and found to be 0.62 for the pneumococcus and 0.87 for the *Bacillus coli*. On the next day, June 12th, the indices were respectively 0.81 and 1.22, and a vaccine was given, consisting of 50 millions of *Bacillus coli*, made from a culture grown from the pus, and 10 millions of a stock vaccine of pneumococcus. There appeared to be very little improvement in the patient's condition, and the opsonic indices taken on June 16th showed the index for the pneumococcus to be still as low as 0.71, though the *coli* index was 1.4.

On June 18th there was found to be a reaccumulation of pus, and a counter incision was made above the crest of the right

ilium and a drainage tube inserted. Through this tube there was free irrigation with Wright's sodium citrate and saline solution.

On the following day, June 19th, the pneumococcal index was low, 0.81, and the coli index 1.05; a vaccine of 25 millions pneumococci and 50 millions *Bacillus coli* was injected, both organisms on this occasion, and subsequently, being isolated from the pus obtained at the time of operation. A rise in the opsonic power of the blood for the pneumococcus took place, and it was not again found below normal. Concurrently, the

patient's condition improved, the temperature became lower, the pulse less rapid though still very feeble, and the purulent discharge gradually ceased, though not before there had been a considerable amount of sloughing of the wound margins. On July 6th it was first noticed that a faecal fistula had formed, and the patient suffered great distress from the excoriation of the skin in the neighbourhood of the wound.

The range of the opsonic index for the two organisms can be well seen on the chart, and also the dates on which the injections of the two organisms were given, the amounts of which were as follows:

Date of Blood Examination or Injection.	Opsonic Index for Pneumococcus.	Opsonic Index for Bacillus Coli.
June 11th, 1908 ...	0.62	0.87
(June 12th)	0.81	1.22
.. .. .	Injected 10 millions	Injected 50 millions
June 16th	0.71	1.4
(June 19th)	0.81	1.05
.. .. .	Injected 25 millions	Injected 50 millions
June 21st	1.28	—
(June 23rd)	1.5	1.14
.. .. .	Injected 20 millions	Injected 40 millions
June 25th	1.27	1.22
(June 27th)	1.75	1.13
.. .. .	Injected 30 millions	Injected 60 millions
June 30th	1.46	1.4
July 3rd	1.19	1.14
(July 6th)	1.92	0.9
.. .. .	Injected 15 millions	Injected 30 millions
July 14th	1.5	1.3
.. .. .	Injected 20 millions	Injected 40 millions
July 20th	1.21	1.4

After the date of the last opsonic estimation the patient's condition was so satisfactory, except for the presence of the faecal fistula, that it was not considered necessary to give further injections of bacterial vaccines, and hereafter the treatment was of a surgical nature.

On July 26th she was taken to the operating theatre and the wound examined under an anaesthetic with the view of closing the fistula. The opening in the bowel was nearly the size of a shilling and as the patient was not in a condition to bear a prolonged operation, a purse-string suture was passed round the opening and a closure made. This, however, broke down again in the course of a day or so, and the condition was as bad as ever, except that the skin had improved around the wound.

Her general condition subsequently improved greatly. She took her food well and gained weight. Though the patient desired that the fistula should be closed it was wished to postpone this for a time in order to allow of absorption of adhesions.

Operation for Closure of Faecal Fistula (by Dr. Harrison).

On September 28th after chloroform had been administered, an incision was made to the left of the discharging sinus, after the opening in the bowel had been plugged with gauze. Except close to the faecal opening there were found to be few adhesions, so a transverse incision was made and the structures forming the abdominal wall divided with scissors round the opening in the bowel. The loop of intestine was then freed, and the opening, which was as large as a shilling, sutured in the transverse axis of the bowel with Lembert sutures. When this was completed the packing which had been placed round the site of the operation was removed, the part was then swabbed with carbolic solution, and the abdominal sutures were about to be inserted when a great gush of intestinal fluid was seen in the wound. When this was swabbed up it was found that there was a second, very large opening in another coil of bowel situated rather deeply in the right iliac fossa. Fresh packing was then inserted and the rest carefully examined, when it proved to be a much larger opening than the first, triangular in shape and involving almost the whole circumference of the gut. The opening being so large and irregular and so deeply seated it was with great difficulty that a double row of sutures were inserted to close it. The whole operation lasted nearly two hours and the patient bore it much better than had been anticipated, although saline infusion and strychnine injections were thought necessary.

After the operation the patient's progress was uninterupted. The openings in the bowel proved to have been satisfactorily closed and there was no further faecal discharge. The large wound filled with healthy granulation tissue, was quite healed when the patient left hospital on November 12th. The bowels were then acting quite regularly. She is at the present time quite strong and well.

THE INDICATIONS FOR NEPHROPEXY.*

BY

WILLIAM BILLINGTON, M.B., M.S.LOND., F.R.C.S.,
SURGEON TO OUT-PATIENTS, QUEEN'S HOSPITAL, BIRMINGHAM.

This paper is the outcome of an experience of 150 cases upon whom I have operated for movable kidney during the past three years. First, it is necessary to refer to the surgical results, for these must be taken into account when discussing the indications for operation. The operation performed I have already described at length in the *BRITISH MEDICAL JOURNAL* of November 29th, 1907. In 96 cases one kidney only was fixed, while in 54 both were dealt with at the same time. Few changes have been made in the technique. I now use kangaroo tendon, medium size, instead of silk for suturing the capsular flap in place. This avoids the leaving of any non-absorbable material in the wound. Drainage of the cavity below the kidney by means of a strand of gauze is employed in every case. The gauze is removed in forty-eight hours. This prevents the accumulation of serum, and appears to diminish post-operative discomfort. At the end of the month, when the patient is allowed to get out of bed, a special belt is supplied. This belt is worn for six months. It is shaped to clear the hips and come down in front as low as the pubes. Just internal to each anterior superior spine are placed two soft pads covered with wash-leather. The object of this belt is to exert pressure over the lower abdomen in such a way as to push the intestines up towards the kidneys. The small pads give a little extra pressure immediately below the kidneys. The belt was made for me by Messrs. Salt, of Birmingham. The diagrams sufficiently explain its main features.

In my original paper I stated that where both kidneys are movable it is better to operate on one rather than both. My reasons for this statement were that the risk to life was less and the improvement which followed the single fixation was so marked that a second operation was rarely necessary. Extended experience has led me to correct this view, and I now know that when both kidneys are movable it is better practice to fix both. The double operation does not add materially to the risk, increases the prospect of complete cure, and spares the patient the possibility of a subsequent operation. It has been a surprise to me to find that double nephropexy is followed by no more shock or general disturbance than the single operation.

* A paper read before the Midland Medical Society.

The surgical results of nephropexy have been very satisfactory. Of the 206 kidneys dealt with, not one, to my knowledge, has become loose again. On one occasion, eight months after operation, I found a movable lump in the right side, which I thought was the right kidney. This opinion was confirmed by several observers. As the patient, though better, was not well, I decided to refix the kidney. On opening the loin, however, the kidney was found to be firmly tethered in its proper position, and the lump which was felt before operation was found to be a freely movable Reidel's lobe of the liver which was attached to the rest of the liver by fibrous tissue only. It was interesting to see that the capsular flap over the rib had become thickened into a strong band of fibrous tissue $\frac{1}{4}$ in. wide and $\frac{1}{2}$ in. thick. I have never had a permanent sinus of the back, a hernia, or weakness of the scar. Amongst the 150 cases there have been two deaths.

I have already recorded the first, which occurred in the case of a man operated on during an attack of mania. He went on very well for three days, but died on the fourth day in a state of collapse. There was no apparent cause for his death, and a *post-mortem* examination failed to show why he died.

The second case was that of a flabby woman who had been a semi-invalid for eighteen years. Both kidneys were found badly displaced. The wounds healed by primary union, and she was thought to be nearly well. On the fifteenth day, after a heavy sleep, she woke up complaining of pain in the chest and a feeling of suffocation, and died in a few minutes. The probable cause of death was cardiac thrombosis.

These deaths emphasize the fact that no major operation

because a kidney is movable so long as it gives rise to no trouble; in other words, simple mobility does not constitute an indication for operation. I would also at this point emphasize the fact that it is fallacious to suppose that the amount of trouble caused by a kidney is to be directly measured by the degree of its mobility. I have seen kidneys which were only slightly movable responsible for most severe symptoms, and, on the other hand, have seen the right kidney in the iliac fossa in people apparently in good health.

Group 1.

This group contains those cases whose predominant symptom was local pain. The pain is due to the perirenal inflammation resulting from recent sudden displacement of the kidney, to ureteral obstruction, or to obstructed venous return. I have known it simulate pain due to gall stones, to appendicitis, or to renal calculi. It may be so severe as to incapacitate the patient. The pain I am now referring to must not be confused with the dragging, aching pain in the back and sides which is much more commonly associated with movable kidney, but which is due to drag on surrounding structures, and is much more vague in character.

In August, 1908, I operated on a young woman who was sent to me by Dr. Garman of Great Barr. She had a very movable right kidney, and complained of "gnawing pain" in her right side. At times the pain assumed the characters of typical renal colic, and required morphine for its relief. Rest in bed was

Fig. 1.

Fig. 2.

is free from risk. They might, however, have occurred after any major operation performed on the same individuals. I have had no mortality from shock, haemorrhage, sepsis, or uraemia, which may be regarded as risks special to operations on the kidneys. With a full sense of the responsibility attaching to my statement, I say that nephropexy is as safe and as satisfactory a surgical procedure as radical cure of hernia. If it can be shown that in properly selected cases nephropexy is followed by real improvement as regards the health and working efficiency of the individual, there are no surgical reasons why it should not be done. No surgeon would say that radical cure of hernia is absolutely safe, and yet no surgeon would refuse to operate in a suitable case in view of the functional gain the operation gives. All I claim is that the same view be taken in respect to nephropexy, provided it be shown that equal gain be obtained from it.

No useful purpose would be served by giving a long list of the symptoms that may be attributed to movable kidney. It is the clinical picture depending upon the association of several symptoms which is so characteristic, and not the presence of any particular symptom. My cases arrange themselves naturally in four groups. I intend to describe briefly the characteristic features of each group and the indications for operation in that group. A fifth group, where the predominant complaint has reference to the female pelvic organs, might be described, but of these cases I have had insufficient experience to speak definitely. Before, however, proceeding to discuss the indications for operation, I wish to state that in my opinion it is not necessary to operate

always followed by entire disappearance of the pain. Complete relief followed nephropexy.

I have also operated upon a girl who was sent to me by Dr. Tangye of Coventry. She complained of pain in the right side, which was so severe as to prevent her doing her work as a parlourmaid. The right kidney was very movable, but the situation and character of the pain were such as to render it doubtful whether the kidney or appendix was at fault. I examined the appendix at the time of operation and found it to be quite healthy.

Two years ago I saw a lady, who stated that some months previously, while laughing violently in a theatre, she was seized with intense pain in the right side. The pain persisted, and she had to stay in bed for several weeks. A diagnosis of gall stones was made, and this was supported by the presence of an ill-defined, acutely tender swelling below the right costal margin. The acute symptoms subsided with rest in bed, and the right kidney was then found to be movable and tender. The kidney was fixed, and since then she has remained perfectly well.

There is another type of case in which local pain is very marked. The pain is more or less constant while the patient is up and about, and is made worse by exertion and stooping. Lying down quickly brings relief. I have seen five men who were incapacitated for work on account of pain of this type. The right side was affected in each case. In four the right kidney could be felt, but was only slightly movable, while in the fifth case the kidney could not be felt. The pain is referred to the loin, and from there radiates forwards along the costal margin, and upwards to the shoulder-blade; only occasionally does it extend along the ureter to the groin. All my cases have been men, and all have been engaged in heavy work or had met with an accident. In several the urine has con-

tained a little albumen, but neither pus nor blood. I have operated on two cases, and in each found the kidney displaced a little downwards and forwards, with the lower pole rotated inwards and surrounded by numerous adhesions. In other respects the kidneys were healthy. I believe the pain is due largely to obstruction of the ureter as it passes over the lower pole of the kidney. The mechanism is sufficiently explained by the illustrations.

The result of operation for the relief of local pain is excellent, and I think every one agrees that renal pain in association with mobility of the kidney is a sufficient indication for nephropexy when the pain is so severe or so persistent as to cause serious inconvenience. With regard to the second class of case which I have mentioned, I would advise exploration of the kidney with a view to nephropexy, even though the kidney were only slightly movable, provided that the pain was sufficiently severe to prevent the patient following his occupation. The important point to ascertain in these cases is whether the pain is made worse by the upright position and by exertion, and is relieved by lying down.

Group 2.

In this group I have placed cases whose predominant troubles were associated with the digestive system. In almost all my cases symptoms referable to the stomach or colon have been present, but in some these have been the chief cause of complaint. The cases present quite charac-

Fig. 3.—Normal kidney.

Fig. 4.—Rotated kidney.

teristic features. They complain of flatulent dyspepsia, vague abdominal discomfort, and constipation. Vomiting is not usual, but there may be paroxysmal attacks of sickness, when everything is vomited back. The symptoms bear no very definite relationship to the taking of food, and may be at their worst several hours after a meal. Colon pains of all kinds are common, and the colon may be distended and thickened. Twice I have operated when mucous colitis existed in association with right dropped kidney, with great benefit. Generally there is loss of weight, and, if the patient has had to lead an active life, there may be great emaciation. These symptoms are associated with more or less hypochondriasis, irritability of temper, and restlessness. The history in all my cases has been a long one, in some extending over eighteen to twenty years. All kinds of medicines and diets have usually been tried without benefit. The only remedy that gives real relief is prolonged rest. On examination, nothing definite can be found. Often the stomach is moderately dilated, but there is no evidence of pyloric obstruction. The colon may be thickened, and a little tender on firm pressure. Usually, it is the right kidney that is movable, but often the kidney is not tender, and there are no symptoms which can definitely be attributed to it.

In March, 1908, I saw a married woman, aged 36, a patient of Dr. Newton. For twenty years she had suffered with her stomach. This took the form of periodical crises of severe epigastric pain and vomiting. On several occasions she vomited blood in large quantities, but there had been no hæmatemesis for five or six years. For the last two years she had been much worse generally, and was unable to do any work

—the epigastric pain was severe, and she suffered much from flatulence and constipation. When I saw her she had just recovered from an attack lasting nine days, in which the pain was intense and large quantities of bile were vomited. Medical treatment was quite useless, rest in bed being the only thing that gave relief. She was a stout, pale, flabby woman. There was diffuse tenderness over the whole abdomen, but no special tenderness in the epigastrium. The stomach was of moderate size. The right kidney fell into the iliac fossa on standing up.

I advised fixation of the right kidney, for these reasons: (1) that the kidney was obviously displaced, (2) the symptoms, though severe, were periodic and induced by exertion, (3) there was no direct evidence of ulceration of the stomach or of pyloric obstruction.

For some months after operation all her troubles disappeared, and she was able to eat ordinary food and do her housework, and said that she felt better than she had done for years. After indulging in a heavy meal of pork chops she had a mild attack of pain and sickness, and since then has had to be careful with her diet. All acute symptoms have subsided, and she looks, and says she feels, much better than formerly.

In September 1906, I saw, in consultation with Dr. Suckling, a widow, aged 50. She had been ill for ten years with "indigestion." She complained of flatulence, fullness at the stomach, and pain at the pit of the stomach after food. No vomiting. She also suffered with frontal headaches, backache, and general weakness. During the last year she had been much worse. The patient was a short woman, and weighed only 6 st. 8 lb. She was very thin. The stomach was distinctly dilated, and waves of peristalsis could be seen crossing it from left to right. There was no tenderness in the epigastrium, and no lump could be felt in the neighbourhood of the pylorus. Both kidneys were movable, the right to a marked degree. The urine contained albumen. Right-sided nephropexy was

performed. She did very well, and is now much better than she has been for years.

Great care is necessary in this group to exclude gross lesions of the stomach and intestine and mistakes are easily made. In some doubtful cases an exploratory laparotomy may be advisable before performing nephropexy. When, however, other causes have been excluded there remain a number of chronic cases not relieved by general treatment in whom great benefit follows fixation of the kidneys. I have operated on 20 cases similar to the above, and have every reason to be satisfied with the results.

Group 3.

Cases suffering from spinal and cerebral neurasthenia. This is a large group. The leading symptoms are severe and persistent headache, backache, constant "tiredness," periodical fits of black depression, and absolute lack of the joy of living. The greater the necessity for work the more pronounced the symptoms. Married women cannot do their housework, teachers complain that the strain of standing and teaching causes complete mental and physical prostration, and business men state that they cannot concentrate their minds upon their work, lose their grip of detail and find that everything, even the writing of a simple letter, requires great effort. These people are irritable, restless, and miserable, a nuisance to themselves and all around. They are painfully conscious of their inefficiency in comparison with other people, are most anxious to do what they can, and generally go on working, until a complete breakdown occurs. They eagerly grasp at anything which holds out a prospect of relief, and have

usually tried all kinds of remedies and been under the care of many different medical men. Some of them complain of occasional insane impulses, usually of a suicidal nature. These form a link between this group and the next, in which I have placed those cases that were undoubtedly insane.

I cannot do better than refer to one or two cases to illustrate the simple neurasthenia and neurasthenia with insane impulses to which I refer.

In October, 1907, a married woman, aged 23, was sent to me by Dr. Duncan, of Hockley. She was suffering from severe neurasthenia, dragging pains in the abdomen when standing, and amenorrhoea. She was unable to do her housework or to walk outside without assistance. Latterly she had been compelled to stay in bed. Medicines and general treatment were useless. The right kidney, which was badly dropped, was situated in place. Since then she has been very much better, and, though not a strong woman, is about and doing her housework.

In March, 1908, a lady, aged 57, was sent to me by Dr. Snckling. She had not been well for twenty-two years. She complained of great weakness and aching of the back, which was so bad that she could neither walk nor sit with comfort. When visiting her friends or going to the theatre she took with her a board, against which to lean. She said that she could get no pleasure out of life, and as she could not get about, life was not worth living. Belts had been tried without much benefit. Both kidneys were down, but the left much more so than the right. As her heart was weak and there was albumen in the urine I decided to fix the left kidney only. She did very well and six weeks after the operation climbed to the top of the Herefordshire Beacon. She has enjoyed a great deal since and has led a far more active life than most women of her age and has done more and felt better than she has done for years.

In August, 1908, I operated upon a woman, aged 45. For many years she had suffered from depression, "funny feelings" in her head, constant tiredness, and flatulence. During the last year she had been worse, and had been compelled to give up her housework. A prolonged holiday in the country brought no relief. Lately she had developed symptoms of insanity, attempting suicide on three occasions, and threatening to murder her child. She was a flabby woman, talkative, excitable, and at times very depressed. Both kidneys were badly down. She began to improve at once after the operation, and a few days ago her husband informed me that she was a different woman altogether.

These cases are selected from amongst nearly 80 upon whom I have operated for very similar symptoms. The results have been surprisingly good, and in some cases difficult to credit. There have been failures, but I can honestly say that no case has been made worse by operation.

To Dr. Snckling belongs the credit of directing attention to the close connexion there is between certain types of neurasthenia and movable kidney. From my own experience I can thoroughly endorse his assertion that such patients are greatly benefited, and in some cases entirely cured, by nephropeky. My results amply justify me in saying that comparatively young and healthy people suffering from progressive neurasthenia who do not improve under medicinal and general treatment, or, having improved, rapidly relapse on returning to the ordinary conditions of life, should be examined for renal mobility. If the kidneys are mobile, and there are no conditions present which would render the operation dangerous the patient should be told that nephropeky would probably be followed by marked improvement. In such cases it is unfair to regard the condition as incurable until the kidneys have been fixed. Time must be allowed for improvement. I make it a rule never to estimate the results of the operation until six months afterwards. Some cases improve slowly, and the full benefits of the operation are not evident for many months. Further, rapid improvement may be deceptive and relapse occur later. If, however, judgement is withheld until six months have elapsed and the patient has returned to the ordinary conditions of life, results can be much more safely estimated. Relapse is exceptional, and one of my oldest cases, operated upon nearly three years ago, whom I saw a few days ago, assures me that she has been better in health than at any time in her life, in spite of the fact that she has passed through some exceptionally trying experiences since the operation.

Group 4.

In this group are placed cases of undoubted lunacy. I have operated on twelve people who were quite insane at the time of operation, and who would have been sent to an asylum immediately had not operation been advised. One of these cases died on the fourth day. Three have

been operated on so recently as to be of little value. One of these had been in an asylum eighteen months and discharged partially cured. She relapsed at once on returning home. A second suffered from profound melancholia, and would neither eat nor speak for twenty-four hours at a time. A third, a man, had been compelled to give up his business, had threatened to commit suicide and murder his wife, and on two occasions had given himself up to the police on imaginary charges. These three cases are improving, but insufficient time has elapsed to make it safe to say what the result will be.

The fifth case was a woman of 45, who suffered from active melancholia. She shouted for hours together, wept copiously, did not know her husband or friends, and was obsessed with the idea that her doctor was responsible for her trouble. She was wasted to a skeleton. Double nephropeky was performed, and for five weeks there was no improvement. The operation was performed on October 6th of last year, and she is still under observation in a home. She is very much better, sews and knits, helps in the cook, and takes great interest in all that goes on. Further time is needed before any conclusion can be arrived at.*

A sixth case, a lady aged 38, a patient of Dr. Stanley, of Coventry Road, was operated on in March, 1908. For six months she had been quite insane and had been sent away from home in charge of two nurses. She was suffering from profound melancholia and fixed delusions, and would take no notice of her husband, her children, or the people around her. Both kidneys, which were badly down, were fixed. For some weeks she made little or no progress, but on leaving the nursing home she began to improve. All symptoms of melancholia disappeared, and, except that she was excitable, she appeared well. Within the last week, as the result of the illness of one of her children, lack of sufficient rest, and excitement, she has become very excited and needs supervision. The probability is that with rest and care she will come all right, but she cannot yet be classed with those who are well.†

The remaining six cases were all well when last heard of. Two had suffered from mania, two from melancholia with suicidal impulses, one from mania complicated by delusions and homicidal impulses, and one from delusional insanity. I can only refer to three.

In May, 1908, I was asked to meet Dr. Berlyn in consultation upon a young lady, about 30 years of age. She had always been of a highly-strung nervous temperament, but remained in fair health until August, 1907. Then, after a mental shock, she became very excited and almost maniacal. Recovering from this she became very depressed. This ended in December in an attack of acute mania. In this attack she was seen by Dr. Stanley Barnes. She was sent to a nursing home, where she improved sufficiently to be sent to Torquay. While away she was practically well, but immediately on her return to Birmingham relapsed, and became maniacal again. In this attack I saw her. Both kidneys were moderately dropped. Learning from Dr. Barnes that no other treatment was likely to benefit her, I performed double nephropeky. After a time she began to improve, and now the friends say that except for absent-mindedness, and a rather dreamy disposition, she is well.

In June, 1907, I saw, in consultation with Dr. Lewis, of Perry Barr, a girl 28 years of age. She was full of silly ideas of all kinds, had escaped from her friends, and raced through the streets without her hat. To do this she had climbed over the wall into the next garden, and from there into the street. Amongst other delusions she had that of being the wife of a prominent statesman. She was so noisy and troublesome that a trained nurse declined to look after her. The right kidney was moderately prolapsed. I had a septic finger at the time and was unable to operate. At my request, Mr. Barling very kindly operated for me. For a while she was very bad, getting out of bed and at times being very violent. In six months she was quite well, and has remained so since.

In April, 1908, at Dr. Snckling's request, I operated upon a lady 33 years of age. She had been certified as a lunatic, and was on her way to an asylum when seen by Dr. Snckling. She was suffering from melancholia with marked suicidal tendencies, having attempted suicide on three separate occasions. Both kidneys were very movable, and at the time of operation were found on banded in dense perirenal adhesions. The capsules were thick and studded over with thick opaque patches. The wounds healed by primary union.

During the first few weeks she made little progress, being very quiet, introspective, and miserable, and was never left alone. For several months she was kept in a nursing institution. A few days ago I heard that she was quite well mentally and had improved greatly in general health.

I advance no theory; I merely state facts. I have operated on twelve lunatics, not one of whom is now in an asylum. Six are well, and of the remaining five still living I have every hope that time will complete the improvement that has already commenced. I do not assert that movable kidney is the sole cause of the insanity in these cases, but I do say that in a person of unstable mental equilibrium it

* This patient is now quite well and performing the usual duties of a housewife.

† Since this paper was written this patient has been sent to an asylum.

is sufficient to turn the balance. Removal of other so-called causes of insanity, for example, alcohol, business strain, etc., is followed by cure in a certain percentage of cases. I contend that removal of the baneful influence exercised by a loose kidney will also be followed by a definite percentage of cures. This, however, cannot be effected by general treatment, or the special treatment carried out in asylums, but by operation alone. My results surely justify the contention that where the kidneys are found to be movable in an insane person, in justice to the patient and the friends, nephropexy should be advised before the case is sent to an asylum.

GENERAL SUMMARY.

1. Nephropexy is a safe and satisfactory surgical procedure.
2. Renal mobility alone is not an indication for operation.
3. Local pain of sufficient severity to diminish working efficiency is an indication for operation.
4. Chronic functional disturbance of the digestive system may be caused by movable kidney. Such cases often resist all kinds of general and medicinal treatment, and are greatly benefited by nephropexy.
5. Nephropexy is indicated in progressive spinal and cerebral neurasthenia occurring in association with movable kidney, when other measures have failed to cure, or improvement is followed by rapid relapse.
6. Nephropexy is indicated when movable kidney is associated with insanity.

LIPOMA IN THE SITE OF A FEMORAL HERNIA.

By C. J. PATTEN, M.A., M.D., Sc.D.,
PROFESSOR OF ANATOMY, SHEFFIELD UNIVERSITY.

IN a young male subject, aged 25, I observed a tumour in the thigh occupying the position of a femoral hernia. To the touch it seemed pliable and to a certain extent reducible, though from the first I had my doubts as to whether it was a hollow knuckle of tube which I was manipulating.

I made this digital examination before the subject was injected with preservative fluid, and being undecided as to what the tumour was, I proceeded to inject the subject with formalin with a view of hardening the viscera for special purposes.

I was glad that I adopted this reagent, as it also proved most useful in hardening and fixing the shape of the tumour, which on further examination proved to be a lipoma. On dissecting down on it, I found that the saphenous opening had been much encroached upon, and it was only with the greatest difficulty that I could detect the remains of the much stretched

occupied the crural canal, and, moreover, blended with a well marked septum crurale, and that the long saphenous vein was pushed aside in an outward direction, were points which were made out with little difficulty. When the front of the mass was well cleaned and defined it was seen to be elongated in shape, its longest measurement being about 5 in., its broadest measurement 2 in. This surface was much lobulated, and two tongue-like processes could be seen projecting upward and inward. The inner of these burrowed between the adductor longus and adductor brevis; the outer between the adductor brevis and pectineus. On endeavouring to shell out the mass I found it to be anchored by several other processes which had burrowed their way through muscular strata. Thus a portion of the tumour passed outward under cover of the femoral vessels (and apparently outside—that is, behind—the femoral sheath) and vastus externus; another part proceeded upward and outward in the interval between the psoas and pectineus. These last two processes could not be seen until the tumour was partially dislodged, as they took origin from the deep aspect. On removing the tumour from its bed I found that its deep surface was much broader and flatter than its superficial surface, and was not studded with small lobules. The floor of the space occupied by the tumour was formed by part of the anterior surface of the adductor magnus. The fascial covering, which formed a very delicate lipoma-capsule, seems to have been derived from the fascial envelopes of the various muscles in the neighbourhood. The cavity in which the tumour lay was 2 in deep, and presented the following boundaries in a fairly definite manner:—Inside, adductor longus and adductor brevis; outside, pectineus and femoral vessels; floor, adductor magnus; roof, integument, superficial and cribriform fascia, and higher up the anterior wall of the crural canal; upper limit, Poupart's and Gimbernat's ligaments.

The circumscribed position which this mass of fat occupied renders this case interesting, though at the same time difficult to explain. Fat was not unduly collected together in other regions; in fact the subject was on the whole rather spare. The corresponding region of the other (right) thigh bore no evidence of fat deposit other than the ordinary layer of superficial fascia. The muscles of the body generally had not shown signs of having undergone fatty degeneration. There is just one suggestion which I would offer, namely that this aggregation of fat at the site of a femoral hernia may possibly have represented a hypertrophic condition of the septum crurale, which is mainly composed of extraperitoneal fatty tissue. Indeed the presence of a firm plug of fat, which quite filled up and even distended the crural canal, and which, on the one hand, was in direct continuity with the rest of the tumour, and, on the other hand, with the enlarged, fat-laden septum crurale, would seem to point to such an origin.

BILATERAL NEPHRO-LITHOTOMY.

IN WHICH THE KIDNEY WAS KEPT OUTSIDE THE WOUND FOR SEVEN DAYS BEFORE RETURNING IT TO THE LOIN.

By JOHN CLAY, F.R.C.S.

ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE;
DEMONSTRATOR OF ANATOMY, UNIVERSITY OF DURHAM.

WHEN both kidneys contain stones, the mortality of the operation for the removal of the stones is very high, and any modification of the usual procedure which promises to diminish the risk is worth consideration. In the case given below both kidneys contained a large number of stones, the urine contained thick pus, and the patient was in a weak and exhausted condition. After removing the stones from the right kidney it was not, as is usual, returned to the abdominal cavity, but was kept outside the wound for seven days. By doing this, the possibility of losing our patient from hæmorrhage was reduced to a minimum, as bleeding points could easily be seen and dealt with. It also seemed that the place for an organ, dripping with decomposing urine and pus, was outside the abdominal wall, and not in its loose soft bed in the loin.

The following are the notes of the case:

Eliza S., aged 34 years, married, was sent by Dr. Spencer, of WallSEND, on April 15th, 1908, to the Royal Infirmary under my care.

View of the tumour from the loins, after removal of the cribriform fascia and the anterior wall of the femoral sheath. The lobulated character of the lipoma and two ascending processes are apparent. The long saphenous vein is seen displaced outward.

and thinned-out cribriform fascia which gave a partial covering to the anterior surface of the tumour. That a considerable upward prolongation of the fatty mass

History.—For nearly two years the patient had been in poor health, and had a dull aching pain in the small of her back. For five weeks she had noticed that her urine was thick and opaque, and that micturition was painful and frequent.

On examination the patient was very emaciated, and palpation showed the right kidney to be much enlarged and tender. A cystoscopic examination was attempted, but it was impossible to get the bladder sufficiently clear to see the ureters.

First Operation.

On April 16th, 1908, an oblique incision immediately below and parallel to the last rib on the right side was made. The kidney was exposed and found to be full of stones, occupying both the pelvis and calyces. The parenchyma was so disorganized by inflammation that nephrectomy appeared to be the best way of dealing with it. Before doing so, however, it was necessary to find out the condition of the other kidney. For

Stones removed from the pelvis and calyces of the left kidney, one-half natural size.

this purpose the peritoneal cavity was opened and the hand passed to the other side. The left kidney was then found to contain stones and to be in much the same condition as the right, making it not advisable to remove the latter, but to remove the stones from it. The right kidney having been brought out of the wound, the stones were taken from the pelvis and calyces. Haemorrhage was controlled by putting clips on the vessels, as, owing to the sepsis present, suturing the kidney substance was to be avoided.

The tissues were so friable that ligatures would not hold. For this reason, and for those given at the commencement of the paper, I determined to treat the kidney extraperitoneally, and keep it outside the wound well wrapped in gauze. The free haemorrhage showed that there was no tension on the pedicle.

The bed from which the kidney had been removed was packed with gauze, and the patient returned to bed. In the after-treatment proctolysis was employed. On the seventh day after the operation an anaesthetic was given, the gauze removed from the loin, and the kidney, which was now covered with healthy granulations, returned to its place.

On May 18th, 1908, the patient was sent home considerably improved.

Second Operation.

She was readmitted on August 6th, 1908, to have the stones removed from the other kidney. At the second operation, as the previous one had been so satisfactory, exactly the same course was followed, but this time the kidney was returned to its bed four days after bringing it out on to the abdominal wall.

She again made an excellent recovery.

On December 3rd, 1908, she was shown to the members of the Northumberland and Durham Medical Society. She had greatly improved in appearance and expressed herself in every way relieved.

After the first operation the patient was very ill indeed, and her recovery was largely due to the skilful manner in which Sister Mathewson managed the continuous rectal injection of normal saline solution.

Though the plan of keeping the kidney outside the wound was adopted on the spur of the moment, yet, as it diminishes the dangers of attempts to save lacerated or septic kidney, I think it is an addition to the conservative surgery of that organ.

REMOVAL OF A LARGE VARIX OF THE ORBIT.

By SIR WILLIAM J. COLLINS, M.S., M.D.,

B.Sc. Lond., F.R.C.S. Eng.

FURGERON TO THE ROYAL EYE AND LONDON TEMPERANCE HOSPITALS
OPHTHALMIC SURGEON TO THE HAMSTEAD AND NORTH-WEST
LONDON HOSPITAL.

Mrs. JANE W., aged 42, had had three children; the last was 7 years old. A fairly healthy woman, always had a high colour, more marked on the right side. Fourteen years ago—some three months after the birth of the last child but one—the right eye began to become prominent. Some large vessels began to show at the inner canthus. For the last three years the proptosis had become gradually more marked. The right eye was projected forwards and outwards on to the cheek, and large worm-like veins

formed a plexus at the inner side of the globe. The lids did not close over the eyeball, and in profile the whole mass projected in a repulsive and unsightly fashion beyond the line of the nose. She had sought advice, but an ophthalmic surgeon had said it was too dangerous to operate on. She was greatly distressed, and was unable to go about in consequence of the deformity. A loud *bruit de diable* was audible with the stethoscope over the orbital swelling. The vision of the right eye was reduced to J. 20; that of the left was 3 and J. 1. The fundus of the right eye showed the veins of the optic nerve rather larger than usual, otherwise nothing abnormal. The pulse was rapid (104); heart sounds normal. There was a large varix in the right thigh, and she had suffered from haemorrhoids. I admitted the patient into the London Temperance Hospital in November, 1905.

November 23rd. Under chloroform I tied the right common carotid artery just above the omo-hyoid. This

Full face before operation.

Profile before operation.

Full face one year after operation.

produced, however, no appreciable effect on the swelling or proptosis.

December 7. Under chloroform I slit the right external canthus freely so as to obtain easier access to the orbital cavity. I excised the eyeball. I found I could pass my finger round the plexus of veins, they being apparently encapsuled and easily detachable from the orbital perosteum. I passed a pair of bent clamp forceps down as far as they would go to the apex of the orbit and clipped the pedicle of the venous bunch. I tied the pedicle with silk after cutting the mass away on the distal side of the clamp. The orbit was then lightly packed with iodoform gauze. The bleeding was astonishingly little. Healing was uninterrupted. The mass proved to be a cavernous angioma, and contained a few phleboliths.

The appearance before and after the operation (a glass eye *in situ*) is shown in the accompanying sketch and photograph. There had been no return up to the end of 1908.

THE members of the first class of Filipino medical students trained under the American rule received their degrees from the Philippine Medical School at Manila on February 27th.

THE APPLICATION OF CONTINUOUS SUCTION IN SURGERY.*

By H. T. HERRING, M.B., B.S.,
LONDON.

THE use of continuous suction as a means of removing blood during operation, and of subsequently draining wounds and withdrawing secretions, has recently received some attention. Dr. R. H. Woods, of Dublin, published an interesting paper in the *BRITISH MEDICAL JOURNAL* of May 20th, 1905, On the Treatment of Purulent Cavities; and a second, entitled, On the Saliva Ejector as a Surgical Instrument, in the *Journal of Laryngology*, February 2nd, 1906. In the last mentioned paper he dealt with the subject as applied to nose and throat operations, and I wish now to endorse what he and others have said, and to advocate

a more extended trial of this agent in general surgery.

I have systematically employed continuous suction, as opposed to intermittent aspiration, for many years, and there can be no question of the benefits conferred on patients, especially after the operation of cystotomy, both as regard their comfort and their general well-being, for they are kept thereby quite dry, and thus relieved of the infliction of frequent dressings, which are imperative under ordinary circumstances. Dryness and the relief thus afforded undoubtedly enables wounds to heal more rapidly, and tends to a lower mortality from post-operative causes.

The chief obstacle which has up to the present prevented the more general employment of continuous suction is, I think, the want of some portable apparatus which can be used in any place, and which will easily maintain a continuous negative pressure without much attention. Neither Cathcart's pump, nor G. W. Richardson's modification, entirely fulfil these requirements.

My first endeavour to overcome this difficulty was with a modified form of Plunkett's well-known saliva ejector, fitted with a Royle's patent tap-union, by which it could be attached to any water supply (Fig. 1). This has proved most successful in many cases. I have used it for more than seven years, and others have tested its capabilities. It works well as a rule, if the water pressure is good, though its action is not very rapid and rather liable to variation. But the great objection to it is that the motive power—that is, the water supply by which it is worked—

is very frequently inconveniently situated with regard to the patient's room, thus rendering a long length of tubing necessary to bring the suction to the place where it is wanted.

With the appliance shown in Fig. 2 that objection is obviated. It consists of a rotary pump, which will mechanically extract air, and a small electric motor to drive it, both being enclosed in a portable box. As almost every house and room has now an electric installation, the motive power exists everywhere, and always close at hand.

Connexion between the motor and the nearest lamp holder has only to be established and the pump is ready to work. This apparatus is exceedingly efficient, extracting 10 to 12 cub. ft. of air an hour, and will produce a high negative pressure (over 29.5 in. of mercury). It will run for days, requiring only to be lubricated occasionally. The weight of the complete apparatus is about 26 lb., and the cost of running it does not exceed

a shilling a day, reckoning the B. T. electric unit at sixpence.

I may mention one or two other points which have to be provided for in order that suction may be successfully applied in surgery.

1. To prevent the blocking of the suction tube in the wound either by the tissues themselves, or by blood clot, mucus, or pus.

2. To provide for the drainage and removal of fluids collected in cavities, or dependent parts not actually reached by the suction tube itself.

The easiest method of draining is to insert the end of the suction tube into one of considerably larger diameter placed in the wound in the ordinary way. The latter acts as a caisson, or well, to collect the fluid, and from which the fluid is sucked as soon as it reaches the level of the aspirating tube. This plan has a disadvantage, for although it prevents overflow and succeeds in keeping the cystotomy patient perfectly dry, yet it does not

drain the cavity, and always allows a pool of fluid to remain below the level of the suction tube. If, however, the caisson is replaced by a porous or absorbent one, which I effect by tightly wrapping several layers of lint or gauze round the lower 3 in. of the suction tube, the result is much better. The fluid is first soaked up into the material, and is then gradually extracted from it and carried away by aspiration. The roll of material must of course extend beyond the lower end of the tube, and be long enough to touch the floor of the cavity and at the same time project above the surface of the skin; for otherwise atmospheric pressure will be unable to act on the cavity, and a negative pressure

Fig. 1.

Fig. 2.

* A paper read before the Surgical Section of the Royal Society of Medicine.

will be established there, when extraction of fluid will at once cease.

Another application of this principle is simply to embed the end of the aspirating tube deeply among the dressings. By either means extraction continues as long as any part of the absorbent dressing touches fluid; so that secretions, etc., percolating into a cavity, are at once absorbed by the material and then extracted and carried away to the receiver by the suction action. The receiver of which I have just spoken is a large bottle interposed between the pump and the suction tube. It catches and retains all the fluids withdrawn, and prevents the blocking of the apparatus.

This pump may also be used to irrigate a wound with any solution desired. One end of a small tube is attached to the outlet of the pump, the other to the short arm of a Woolf's bottle filled with the irrigating solution. A second tube—that which is to convey the fluid to the wound—is connected with the arm extending to the bottom of the bottle. The action, then, of the pump is to force air into the bottle and create a positive pressure, which in its turn drives the solution along the irrigating tube to the dressings in the wound. If a small and continuous supply of solution is wanted, the irrigating nozzle must be quite fine and the pressure regulated by adjusting the escape valve connected with the Woolf's bottle. Thus, a wound may be drained and irrigated at the same time without discomfort to the patient.

Suction has been employed in draining the chest, the kidneys, the gall bladder, the throat and nose, and I think with this more convenient and powerful apparatus a further trial should be given, not only in these cases, but also in all where it is important to remove secretions and discharges.

With regard to the removal of large quantities of water—for instance, when a cavity is being flushed during an operation—the calibre of the suction tube must be considerably increased and provided with a tap which can be turned off, so that the receiver can be partially exhausted before being used. In this way very large quantities of blood and fluid can be rapidly withdrawn in a short space of time.

Messrs. Maw and Sons, Messrs. Allen and Hanbury, and other instrument makers will lend the apparatus to any one who may care to give it a trial.

A FATAL CASE OF LEAD POISONING DUE TO DIACHYLON.

By F. STRONG HEANEY, M.D.DUB., F.R.C.S.IREL.

THE series of cases of diachylon poisoning reported by Dr. Edmund Hay in the BRITISH MEDICAL JOURNAL for January 23rd, and the fatal case reported by Dr. Arthur T. Hall the following week, induce me to place on record a further case which proved fatal twenty-one days after taking diachylon. The case, which was under my care during the seven days preceding death, has not previously been reported. It is interesting as well for the train of symptoms presented and the *post-mortem* appearances as for its bearing on the efforts now being made to stop a widespread evil.

On January 21st, 1908, I was summoned to attend a married woman, aged 25, who was said to have suffered from gastritis for a long time, but to have become worse during the last fortnight. On entering the room I noticed an unusual sweetish sickly odour not to be described in words—a smell *sui generis*; and, on examining the mouth to find a possible cause in carious teeth, I observed a well-marked blue line on the gum margins. The patient was six weeks pregnant, and on being questioned admitted having taken diachylon a fortnight previously. I subsequently elicited the following history:

History.

She was the mother of two children, the younger being about 2 years old. Though in fairly comfortable circumstances, she had always been delicate and anaemic, and had a haunting dread of any further increase in family.

On January 8th, realizing that she was again pregnant, she bought, at the instigation of a friend, a quarter of an ounce of diachylon in mass. She rolled it into nine pills, which she took at short intervals in the course of forty-eight hours. Within a few hours of taking the last of the pills she began to have severe abdominal pains. Hot applications and hot drinks gave no relief, and after a day she began to vomit. Intermit-

ting pain and vomiting continued for four days, then the vomiting ceased, but pain continued as before. During this time the bowels remained constipated. They were slightly relieved by enemata; no magnesium sulphate nor other purgative was given, the patient's stomach being considered "too weak" to stand purgation. On the other hand, morphine was administered to relieve the pains.

About a week after taking the diachylon mental symptoms first appeared. She became sleepless, and at intervals imagined she heard bells ringing, saw herself sitting in snow-drifts, imagined she was falling out of bed, etc. She had occasional attacks of faintness, especially on trying to sit up or turn suddenly in bed.

Condition when First Seen.

I first saw her a fortnight after she had taken the diachylon. She was then very anaemic and emaciated. She lay on her back prostrate, slipping down from the pillows. The skin felt cold (temperature 97°) but not unduly dry or moist. The tongue was dry and furred, and the lips covered with sordes. With the breath was exhaled the peculiar odour referred to above. The pulse was 138, soft and full. The bowels had not moved once since taking the diachylon save as the result of an enema. In spite of this, however, and in spite of a dilated stomach subsequently discovered the abdomen was retracted and flaccid. Urine was being passed frequently in small quantities, and accompanied by pain and burning. Seven ounces, saved the day after my first seeing her, yielded on analysis the equivalent of $\frac{1}{10}$ gr. of metallic lead. The specimen was otherwise normal.

Treatment and Subsequent Progress.

Magnesium sulphate was administered, and seemed at first to relieve two pressing symptoms—the constipation and the delusions. Digitalis and strychnine were given to combat the attacks of faintness. Under their influence the pulse-rate fell from 138 to 120 but gradually rose again to 140. Potassium iodide seemed to be contraindicated having regard to the large quantity of lead already in circulation and being excreted.

On January 26th, seventeen days after taking the diachylon, she complained of severe pain in the left shoulder and upper arm. Next day the pains had disappeared, leaving the muscles of the limb almost completely paralysed. Feeble flexion and extension at the phalangeal joints were the only movements left. Sensation was diminished but not completely lost. On January 28th the same condition appeared in the right arm, and passed through the same phases—first pain, then palsy and partial anaesthesia.

On January 30th the pulse became very rapid and irregular, and on the 31st she died in one of her attacks of faintness. This last phase of "heart delirium" was evidently brought about by implication of the vagi, but up to the end there was no indication of interference with the innervation of respiration.

Necropsy.

The chief features of the *post-mortem* examination, made by Dr. Raw at the coroner's request, were (1) acute inflammation of the mucous lining of the stomach and intestine, extending in some places to actual ulceration, (2) acute fatty changes in liver and heart.

From the evidence at the inquest it would appear that the practice of taking diachylon to produce abortion is prevalent in both Lancashire and Cheshire. It was stated, moreover, that nowadays when a diachylon plaster is required as such it is almost always called for "ready-made"—that is, spread on calico, etc.; in other words, whenever diachylon is demanded in mass the inference is that it is required for an illegal purpose. Even apart from the ethical aspect of the matter, it is regrettable that the class of people who resort to the drug are unaware of its poisonous effects.

Memoranda : MEDICAL, SURGICAL, OBSTETRICAL.

ALCOHOL AS A SURGICAL DRESSING.

For some years it has been the custom in many surgical clinics to use methylated spirit as an agent for cleansing the skin previous to operation, and also for removing the inspissated debris from around the wound at the subsequent dressing. An antiseptic wash of some kind is usually applied to the wound itself. For some time now I have gradually found myself abandoning the use of any antiseptic wash at the dressings, and confining myself entirely to spirit, whatever the nature of the wound. It may temporarily smart, but it is only for the moment. But what I wish to state more especially is that spirit forms a most excellent dressing for wounds. For months I have used it alone in all freshly-incised wounds for whatever purpose—in many cases of radical cure for

hernia, in breast cases, in excision of veins, in three cases of displaced semilunar cartilage of the knee-joint, in abdominal sections, etc., and I find that I have had a larger series of continuous good results than from any other dressing. It is now my custom before closing the wound to bathe the tissues with the ordinary "industrial" methylated spirit, and, after closure of the wound, to apply plain white sterile gauze wrung out of spirit.

The benefit of this dressing is, I believe, due not so much to the antiseptic properties of the spirit as to the powerful affinity that alcohol has for water, thus removing, perhaps, the most essential factor of bacterial growth—moisture. It also lessens in many cases the necessity for drainage, and by its styptic properties shortens the time necessary for securing the smaller bleeding points. When the wound is looked at for the first time after the operation, the small quantity of blood which has oozed from each stitch hole will be found caked and clotted and quite hard.

I should very much like to hear if others have used spirit in this manner, and if they have obtained the same results.

It is well known that whisky and rum were used occasionally as a dressing for wounds before antiseptics were introduced.

JAMES GRANT ANDREW,
Surgeon, Victoria Infirmary.
Glasgow.

TREATMENT OF DYSMENORRHOEA.

IN Dr. Herman's paper (p. 937) on the above subject, he sets a definite limit to the meaning of the word "dysmenorrhoea." It would seem to me that he holds the view that I have for a long time past entertained, and have only seen set forth in one work on gynaecology (American)—namely, that *all* dysmenorrhoeas are really due to spasm—and hence, I think, a more expressive word would be "menorrhspasm."

I believe that true dysmenorrhoea, or menorrhspasm—whether in virgins or married women—arises through nerve causes: that from the consequences of some illness, from anaemia, from overwork, worry, or, perhaps, from a condition of the general nervous system, normally prone to over-excitability or want of balance, the nervous mechanism of the patient is functionally upset, and the generative organs are among the first to feel the strain, and a tropho-neurosis is set up, giving rise to a spasm of the uterine muscular fibre at the time of the period. What is required, therefore, for a rational plan of treatment is to co-ordinate these irregular spasmodic uterine contractions, and, accepting Dr. Herman's theory of imperfect development of the spinal or sympathetic centre, to adopt some method that will stimulate this centre to full function.

I know that to many gynaecologists the mere mention of electricity is "anathema"; but I can assure Dr. Herman or any other practitioner who has to deal with cases of true dysmenorrhoea that if they will try the constant current in conjunction, if possible, with the static wave current in the manner that I will describe, they will find that they will often obtain the most gratifying results. I am certainly not going so far as to say that *all* cases will yield to this treatment any more than to any other, but (especially in the case of unmarried girls) there is a natural and proper repugnance to any direct uterine manipulations, and it is well worth trying to relieve the intense pains that so many girls suffer at the times of the menses, when the attempt can be made without outrage to their feelings.

The method that has given me such satisfactory results on the whole that I think it worth bringing before the profession is as follows:

I first apply the wave current from the negative side of a static machine by means of a long metal electrode inserted into the rectum and pushed well forward in apposition with the posterior wall of the uterus. This procedure is perfectly painless—indeed, it is hardly uncomfortable—and treatment lasts for from ten to twenty minutes. I next apply the constant current, and here the method varies according as one is treating a virgin or a married woman.

In the former case two large copper electrodes (8 by 15 in.) are placed one over the abdomen and the other over

the lower lumbar region, with four thicknesses of moist Gangee tissue between them and the skin, and a current of from 20 to 60 milliamperes passed for ten to fifteen minutes. Three treatments a week for one or two intermenstrual periods will often entirely relieve the pain for many months, and, should there be any return, one or two treatments just before a period will be sufficient. In the case of a married woman, after employing the static wave, I apply the constant current by means of the same two abdomino-dorsal electrodes, only that now both are connected to the same pole of the source of current—usually the positive—while the negative pole is attached to a suitable electrode, which is passed into the uterine cavity. In these cases a current of 10 to 30 milliamperes for ten minutes three times a week will in nearly all cases give relief.

I trust that a fair measure of success in my own practice in relieving this most common cause of suffering will be considered a sufficient reason for advocating a form of treatment, not usually favoured by gynaecologists, to supplement those suggested by Dr. Herman.

HIGH-FREQUENCY CURRENTS FOR INSOMNIA.

IN the papers and correspondence on the subject of Insomnia which have lately appeared in the JOURNAL, and especially those dealing with the treatment of this troublesome complaint, I note that no reference has been made to the very beneficial influence of high-frequency currents in producing sleep.

The value of high-frequency currents in the treatment of various functional and other diseases is, perhaps, not sufficiently recognized by the profession. Unfortunately, when this method of treatment was introduced several years ago, it was unwisely boomed. It was thought that these currents would be of service in all kinds of disease, and installations were introduced into hydropathic establishments and chemists' shops, where they were under the control of ignorant bath men and bath women, and shop assistants without any medical supervision. It was natural, therefore, that not only was no benefit derived by the patient when treated by those unskilled operators, but in many cases actual harm resulted. Consequently, the pendulum has swung the other way, and it is now common for many medical men to assert that high-frequency currents are of little or no use.

After years of experience and careful study by physicians who devote themselves specially to electrical treatment, it has now been determined in what forms of diseased and abnormal conditions high-frequency currents are found to give rise to good results. Among these varied conditions insomnia stands pre-eminent. We have no difficulty in producing sleep by the ordinary methods of drugs, but their results are not permanent; and they are frequently a source of danger to the moral of the patient. Further, while they promote sleep, they usually occasion unpleasant sensations on the day following the administration of the drug.

In happy contrast to the influence of medicinal treatment, the high-frequency currents, when administered carefully by a qualified medical man, induce a sleep that is pleasant in character and has no evil consequences. Further, not only is sleep produced, but the patient derives general benefit from the influence of high-frequency currents. There is a feeling of well-being and of exhilaration produced, which is permanent in character. From personal experience I may state that very few patients who have come under treatment on account of insomnia have not derived great benefit from the treatment. Sometimes the result is immediate, at other times a more prolonged course of treatment is required. I may add, however, that I find it necessary to administer a large amount of milliamperage, reaching 700 to 800 m.a. This maximum is not attained at once, but, commencing with a small dose, one gradually increases the amount till the maximum is reached.

While undergoing this high-frequency treatment, not only is insomnia overcome and the patient placed in a better condition, which is easily recognized by himself, but from chemical analyses of the urine we have learnt that these currents produce an improved metabolism within

the human economy, and that a normal condition of bodily function is attained.

W. F. SOMERVILLE, M.D.,
Medical Electrician, Western Infirmary, Glasgow.

'ULCERATION INTO AORTA DUE TO FOREIGN BODY IN OESOPHAGUS: FATAL HAEMORRHAGE.

ABOUT 10 a.m. on April 5th, 1908, I was called to see a boy of 8 years old who was vomiting blood and passing blood by the bowel. When I saw him he was sitting on his mother's knee. He looked extremely blanched, the lips were bloodless, and he complained of great thirst and pain in the epigastrium. Percussion and auscultation revealed no tenderness or anything abnormal in the thorax or abdomen. The temperature was 100°; pulse 146.

History.

Until the evening of April 3rd he was apparently perfectly well. At 7.30 p.m. on that date, while sitting in a chair, he commenced to vomit and brought up a small quantity of clear frothy fluid. He slept well that night, and got up apparently well the next morning. During the day he played about in the street, and his mother noticed nothing amiss, except that he did not take his food with his accustomed relish.

At about 7.30 p.m. on April 4th he expressed a wish to go to stool, but on the way he suddenly turned faint, and became very pallid. He was at once put to bed, and for the next few hours complained of great thirst. At 9 p.m. the bowels acted, and the motions were quite black. About 11.30 p.m. he vomited "more than a pint" of blood, the first that came being black, and the rest "bright red." The vomiting lasted a few minutes. After that he rested until 2 a.m. on April 5th, when he vomited two lumps of clotted blood, and had a slight action of the bowels, the stools in this instance being also black. At 6 a.m. he vomited a little "phlegm," but no blood. Four years ago, his mother told me, he swallowed a halfpenny, which had never been recovered.

Condition on Admission.

During the forenoon of April 5th he was admitted into the Batley and District Hospital. His condition on admission was one of great prostration. Pallor was very marked. He complained of great thirst and a slight pain in the epigastrium. He had a short dry spasmodic cough. The temperature was 100° F., and the pulse, feeble and thready, was about 150, but difficult to count. An x-ray examination showed a round opaque body in the upper part of the thorax in the middle line.

The diagnosis arrived at was that the haemorrhage was due to ulceration into the aorta, and that the case was inoperable.

He was fairly comfortable until 9 p.m., when he suddenly collapsed, and died in a few minutes, the collapse in this instance being accompanied by oozing of bright-red blood from the mouth and nose.

Necropsy.

A post-mortem examination was made two days later, and the following facts noted. The whole skin was

markedly pale, and there was no post-mortem staining. All the organs were healthy, but almost entirely bloodless. The heart and large arteries were nearly empty. The stomach and intestines were filled with dark blood.

The heart, aorta, trachea, and oesophagus were removed en masse, and a careful dissection made after hardening in formalin. A halfpenny was fixed transversely in the oesophagus. The neighbouring parts of the oesophagus, trachea, and aorta were matted together by fibrous tissue. The wall of the oesophagus at this part was about $\frac{1}{4}$ in. thick, and of almost cartilaginous consistence. The edges of the coin were securely lodged in two deep pockets in the oesophageal wall, and the edges of these pockets were drawn out into fringe-like projections (see drawing). At the bottom of the left pocket there was a small aperture not much bigger than a pin's head, with attenuated edges, communicating with the aorta, through which the fatal haemorrhage occurred.

The halfpenny was quite black. An attempt was made to polish it to find the date, but the figures 18— were all that could be deciphered.

With reference to the length of time the coin had lain in the oesophagus, the account of the mother was checked by that of the medical man who attended the patient at the time the coin was swallowed, and the period certainly fixed at about four years. During all that time the mother stated that the child complained of no inconvenience whatever.

THOMAS LOVETT, M.B., Ch.B.

A CASE OF ACUTE THYROIDITIS.

In April, 1908, at Hong Kong, a male Chinese, about 25 years of age, was brought to me for treatment. He complained of general malaise, of some stiffness and soreness of the neck, and of dysphagia.

He did not appear to be very ill; the temperature was 99.5° F. There was considerable chronic congestion of the pharynx, and many small granulomata on the surface of the mucous membrane. I ordered an alum gargle and some diaphoretic mixture.

He returned in three days, in accordance with instructions. He stated that he felt much worse, found great difficulty in swallowing, and his throat had suddenly swollen. The considerable increase in the circumference of the neck which had taken place was found, on examination, to be due to a general symmetrical enlargement of the thyroid gland. The tumour thus formed was smooth and tense, it did not fluctuate, nor was it pulsatile; there was no pain on pressure, and it was not freely movable under the skin. The symptoms were almost entirely dysphagic, but he complained also of loss of appetite, and his temperature was 100.5° F. I ordered the swelling in the neck to be painted with iodine liniment thrice daily, and potassium iodide in half-drachm doses, combined with a little aromatic spirits of ammonia, three times a day.

In the course of three days the swelling had greatly diminished, and the dysphagia was much relieved. At the end of a week all swelling had disappeared and the patient was feeling a little weak, but otherwise well.

This case is remarkable from its rarity and also from the rapidity with which resolution took place under the influence of potassium iodide, especially in view of the recently reported cases in which the exhibition of this and other iodides in large doses has caused sudden enlargement of the thyroid gland. It is also of interest to note that I had known this patient for some three years, during about half of which time he was in personal attendance upon me, and therefore I am certain he did not possess a small chronic goitre, such as sometimes gives rise to a sudden enlargement of the gland. I know also that he did not come from a goitrous locality. The man, who was very intelligent, assured me that no similar case had occurred in his family, nor were any of them afflicted with chronic goitre.

I would venture to suggest some temporary lesion of the vasomotor nerves which control the blood supply of the gland as the possible cause of such a sudden enlargement.

PORTSMOUTH.

KENNETH H. JONES, M.B.,
Staff Surgeon, R.N.

THE TREATMENT OF GONORRHOEA BY IRRIGATIONS.

In the BRITISH MEDICAL JOURNAL of February 27th, 1909, page 551, Mr. J. J. Moore writes "a plea for more active treatment of acute gonorrhoea." He has treated, he states, "19 cases of acute gonorrhoea within the last four years," and the treatment adopted in these cases was the "daily repeated irrigation (potass. permang. gr. 1 to 10 oz. of boiled water heated to 99° to 100° F.) of the anterior portion of the penile urethra without the administration of any specific internally." Mr. Moore, writing from Sierra Leone, states that this treatment in his hands "has been rewarded with invariable success, the discharge disappearing even in the severest cases within ten to seventeen days, and no complications have arisen in the whole series of cases treated by this method." In large British military hospitals in recent years the irrigation treatment of gonorrhoea has been extensively carried out, and, speaking from a personal experience at Woolwich of 1,203 in-patients so treated in the past four years on the general lines (by no means new) advocated by Mr. Moore, I must confess to a certain amount of surprise at the duration of the disease in the cases cited by him. Were they Europeans? I conclusively showed in an article on the treatment of gonorrhoea, in the *Journal of the Royal Army Medical Corps* of November, 1908, in dealing with acute purulent gonorrhoea, that although the discharge may temporarily stop it commonly returns, and that six to seven weeks is about the average duration of urethral discharge even under the most favourable auspices with in-patient hospital treatment. In some cases gleet persists for months. The prolonged nature of the discharge is corroborated by independent military records in England and in India for fifty years past. Finger, of Vienna, is also of opinion that urethral discharge in gonorrhoea lasts six weeks despite all forms of treatment. The evidence of the Advisory Board Reports on venereal disease in the army, 1904, 1905, and the further valuable testimony of Major Blenkinsop, R.A.M.C., in an official report dated Simla, August, 1908, who visited sixty-four military stations to test these matters, amply endorses the prolonged nature of urethral discharge in many cases.

When a medical student, some twenty years ago, I heard (but never saw) of cases of gonorrhoea cured in three days. I did once, however, later see a case in which the discharge stopped within this period. The patient was an officer under orders for active service, who being naturally anxious to get rapidly well, and contrary to advice, underwent treatment at the hands of a prescribing chemist. The discharge stopped in three days, as the result of orchitis, and he travelled with me to South Africa nursing two enlarged testicles. He was left at the base, and is presumably impotent for life. It is cases such as these where a rapid cure is reported to have been effected that not infrequently develop gonorrhoeal arthritis or systemic infections at a later date. I commonly see a urethral discharge stop within less than seventeen days, and as commonly see it return, and this is the general experience of the medical profession. Microscopic examination of the centrifugized deposit in the urine will very soon demonstrate to the close observer that the case is not really cured, as the gonococcus in uncomplicated cases can be recovered up to six weeks or longer, and pus and epithelial cells for a longer period. If pus cells are present, relapse commonly occurs, although there may not have been any obvious urethral discharge for a period of fourteen days to one month, and marriage is contra-indicated. In cases of posterior urethritis and orchitis, however, the gonococcus can be recovered up to three months or longer from the urine, and the micro-organism lies latent and recrudesces; such cases might be described as ambulant gonorrhoea or gonorrhoea carriers, and in civil life the danger to women is very great. In the army such cases are kept in hospital, and at Woolwich under observation on discharge from hospital, with benefit to themselves and the civil population.

H. C. FRENCH,
Major R.A.M.C.

Royal Herbert Hospital, Woolwich.

A society for the prevention of venereal disease has been founded at Warsaw.

UNDER the will of the late Colonel Arthur Saltmarsh, of Sevenoaks, Kent, Guy's Hospital and the Gravesend Hospital each receives a legacy of £500.

Reports of Societies.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Friday, April 2nd, 1909.

Dr. W. H. CHEETHAM in the Chair.

Compensation for Accidents.

In a paper on this subject, Dr. T. CHURTON held that in a disputed case each of the medical witnesses should be required to state in writing the reasons for his opinion as to (a) the exact site of the lesion causing the symptoms; (b) its nature, considered as a distinct and separate problem; (c) its complete causation, with an estimate of the share taken therein by the injury, either directly or by its effects acting in their turn as causes. If, for example, one man asserted that there was in some defined part of the nervous system a chronic inflammation of traumatic origin, and another maintained that there was no inflammation but only (so-called) functional disorder, or no lesion of any kind, each should give his reasons in such a form that they could be submitted to a selected neurologist of judicial position and rank. In respect of the causation of accidents, he drew a distinction between essential, determining, and contributory causes. If in a mass of interdependent organs like the body a lesion produced by mechanical or other force gave rise to a succession of alternating effects and causes, the injury must be held responsible for all of them. As for the meaning of the word "accident," it was variously interpreted in their own interest by different contending parties, and the author doubted whether any condition or event which might be expected to occur in, and as a part of, the ordinary day's work, anything foreseen and certain to happen often or even occasionally, could properly be called an accident. Hence special terms and agreements should be made for hazardous occupations.

Bronchoscopy.

Dr. A. D. SHARP, in a paper on modern methods of examining the larynx, trachea, bronchi, and oesophagus, pointed out that unnecessarily strong solutions of cocaine were generally recommended, and that a perfect anaesthesia could be obtained by using a 5 per cent. spray for the pharynx, 10 per cent. application for the posterior surface of the epiglottis, and 10 to 15 per cent. for the trachea and bronchi. He attributed cases of temporary aphonia following bronchoscopy to faulty anaesthesia and indifferent manipulation. In order to get an extensive view within the trachea the distal end of the bronchoscope must be controlled so as to keep it in the centre of and parallel with the trachea, as there was a tendency for the end of the tube to direct itself against the anterior wall. Care must be exercised in withdrawing the tube as slowly as it was introduced, to prevent the end tilting against the trachea or against the cricoid and arytenoids.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

At a clinical meeting on April 26th, Mr. C. B. LOCKWOOD, President, in the chair, the following were among the cases shown:—Dr. F. J. POYNTON and Dr. W. L. SCOTT: Three cases of *Recurrent familial jaundice* in which the predominance of anaemia was striking, and jaundice, though at times marked, occurred only in definite attacks. Mr. V. WARREN LOW: A case of *Congenital dislocation of the hip-joint* treated by manipulation in 1905, resulting in the child walking without a limp, and being able to run and skip. Mr. T. H. KELLOCK: A case of *Traumatic meningo-encephalocoe* cured after lumbar puncture; slight pressure was also applied to the tumour. The child was now shown, more than two years after the treatment. Dr. F. PARKES WEBER: A case of *symmetrical Atrophy of hand muscles* with cervical ribs; skiagrams were exhibited showing cervical ribs in a younger brother and a sister of the patient without atrophy in the hand muscles. Dr. WILLIAM HILL demonstrated *direct vision laryngoscopy* on a female from whom a growth on one vocal cord had been recently removed by endoscopic surgery; also *tracheoscopy* on a female with laryngitis and tracheitis; *tracheo-bronchoscopy* on a

female with laryngitis, tracheitis, and asthmatic symptoms; and oesophagoscopy on a female with functional dysphagia. Dr. LEONARD GUTHRIE: A case of *Progressive muscular atrophy* in a man 39 years of age showing weakness and atrophy of the intrinsic muscles of both hands, of the flexors and extensors of both forearms and of both bicipital muscles.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At a meeting on April 2nd, Dr. SEYMOUR TAYLOR in the chair, the following were among the exhibits: Mr. PARDOE: A case of complete extensor paralysis of the arm after *Excision of the elbow*. The scar was dissected out, and the musculo-spiral nerve found to be cut through just above its division. Anastomosis was performed by end-to-end suture. Dr. PALMER: A case of *Habit spasm* in which irregular spasmodic movements of the face, neck, head, and trunk muscles were markedly present. Mr. N. BISHOP HARMAN: A case of senile cataract with infantilism in a man of 50 years, with the physique of a fat boy and penis of a boy of 2 years of age; he had a well-formed scrotum, but no testes. Mr. E. ARCHIBALD SMITH: A painless *Tumour of the tongue* of ten years' duration in a young woman aged 18, probably a lymphangioma. Dr. SEYMOUR TAYLOR: The heart from a patient who developed a loud heart bruit which was thought to be caused by a torn aortic cusp. After death it was found to be due to an inflammatory thickening of the aorta wall itself. Dr. HALS DALLY (for Dr. ABRAHAM): A case of *Tricophyton endothrix* in a man aged 20, which he held to disprove the statement of Sabouraud of Paris that the disease did not occur in the adult.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—At a meeting on April 20th, Dr. T. JASON WOOD in the chair, the following were among the exhibits:—Mr. HORROCKS: Concretion from an appendix which had burst through into the bladder and become coated with phosphatic deposit. Mr. F. W. GOYDER: A case of serous meningitis treated by drainage through the posterior fossa of the skull. Mr. PHILLIPS, in opening a discussion on the surgical side of *Acute appendicitis*, divided the disease into three types. In the first, the "simple type," there was a certain amount of abdominal pain, tenderness in the right iliac fossa, some fever, and quickening of the pulse. The treatment should be: (a) Absolute rest in bed; (b) nothing except water allowed by the mouth; (c) clearing out the lower bowel by an enema; (d) if necessary a simple carminative mixture. The second type was Type 1 with the addition of swelling in the right iliac fossa. Cases could safely be left till things quieted down. Operation was not advisable at first, as, owing to adhesions and inflammation, it was usually a very difficult procedure. The third type was the gangrenous class—that in which the catastrophes occurred. Diagnosis was very difficult. It rested chiefly on the facial expression and the rigidity of the segment of the rectus muscle overlying the appendix. Immediate operation was the only treatment. The best incision was one just above Poupart's ligament. The pus should be mopped out and a gauze drain inserted. On no account should the peritoneal cavity be washed out. Dr. HONEYBURN, opening the discussion on the medical side, said the main question in any case was How much is the peritoneum involved? The main point in the treatment should be to keep the inflammation of the simple adhesive variety. This was to be done by absolute rest for the inflamed part, and not only should no food of any sort be given, but the bowel must not be disturbed by enemata or any other method of evacuation. A diagnosis established, morphine should be given in full doses, and continued as long as there was pain or tenderness. Operation was never required except in the gangrenous cases. In those, immediate operation gave the only chance. Mr. HORROCKS found that in Type 1, leeches and calomel in two-hourly doses of $\frac{1}{4}$ to $\frac{1}{2}$ grain, followed by an enema, were both useful. In the second type, where the swelling was to the inner side of the iliac fossa, careful watching was required, as the abscess was very liable to track down into the pelvis. Dr. RABAGLIATI said that, in his experience, if left alone the abscess frequently burst into the bowel, and Nature completed the cure. Dr. T. G. WOOD did not think Type 2 was always safe to leave untouched.

The most logical course was to operate in all cases as soon as diagnosed. In this way no harm was done in the cases classed as Type 2, and the gangrenous cases, being taken early, were given the best chance of life. Dr. CAMPBELL agreed that such a course was logical, but it was not always practicable.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting on April 21st, Dr. P. BOOBYER, President, in the chair, Dr. A. C. REID read a paper on the value of *Ehrlich's diazo reaction* to the general practitioner. In this he pointed out the diagnostic value of the test in early cases of enteric fever. The disease must, however, have reached a certain stage before the reaction was present. When this stage had been arrived at the reaction was in his experience constant. It was also constantly present in miliary tuberculosis, but the differential diagnosis of typhoid was not so difficult from that disease as from febricula, gastric fever, abdominal influenza, low bronchopneumonia, etc. The reaction did not merit the neglect it received from the general practitioner. As a negative test it occupied a foremost place, and as a positive reaction when taken in conjunction with other signs, tests, and symptoms it had considerable importance. The President and Drs. F. H. JACOB and O. KENTISH WRIGHT confirmed the value attached to this test by Dr. Reid. In opening a discussion on *The Notification of Births Act, 1907*, Dr. A. J. SHARP traced the changes brought about by the Act in the matter of time, of stillbirths, exemption of the mother, and penalty attaching to medical attendants. He discussed the question as to how far a new duty had been laid upon the medical practitioner. Explaining the object of early notification as the first step in a movement for the reduction of infant mortality, he reviewed the various measures which had already been put into operation. Amongst these were baby-shows, bounties payable on the child attaining a certain age, systematic visitation by voluntary or paid workers, mothers' and babies' welcomes, the encouragement of maternal suckling, day nurseries, milk depôts, school instruction in hygiene, and general sanitary progress. Tracing various objections to the Act, that on the score of professional secrecy was the most serious and persistent, but this had no basis of support in law when a duty became public and statutory. Indeed, as regarded children not born in wedlock, they were above all others the ones who most needed the strong arm of the law to protect them. Their death-rate was at least double that of legitimate children. Dr. S. E. GILL, continuing the discussion, emphasized the point that at the Nottingham Welcome no medical treatment of mothers or infants was attempted, but everything else that could be done in the way of encouraging the poor and inexperienced mother to feed, clothe, and tend her babe in a rational and hygienic way was done. In this way the more intelligent mother would act as a focus of knowledge and an example in her neighbourhood by which the general standard of infant hygiene and parental responsibility might be gradually raised. Indeed, the more aristocratic mothers might indirectly become more disposed to fulfil their natural obligations to their infants, which at present were apt to be shelved in favour of the theatre or playing bridge. The President pointed out that the Nottingham Welcome, although it had only been in existence about eight months, had already secured an average attendance of 200 babies per month. C. L. ROTHERA, Esq. (Nottingham City Coroner), agreed that the subject of infant mortality was one very vital to the health of the nation, and pointed out that the Children Act, 1908, laid down medical aid as a necessary which parents were compelled to provide for their children. He also drew attention to the elaborate system prevailing at Leipzig and elsewhere in Germany, by which children were examined weekly at a central depôt, so that any defect in the matter of health could be promptly detected and dealt with. The discussion was continued by Drs. J. WATSON, J. A. WARING, and W. HUNTER. Dr. W. TIBBLES showed a Siamese gentleman, aged 19, the subject of *Chronic oedema* of one hand and forearm of eighteen months' duration. The case had been carefully examined by Mr. James Cantlie, who had considered the possibilities of its being due to local irritation, synovial inflammation, filaria, ankylostomiasis,

and angio-neuroses, such as urticaria exaggerata, etc. A guess had been hazarded that it might be rheumatic, but there was no reason to attribute it to tubercle or specific disease. Blood examination had shown eosinophile corpuscles to be excessive, which rather suggested an intestinal infection. Indicanuria also existed, raising a suspicion of disturbed proteid metabolism. Treatment by bandaging the hand in thick wool, sour milk internally, and a mixture of ol. ricini cum ol. eucalypti had brought about some improvement, but a careful search in the stools had failed to reveal any parasite. Dr. R. B. PURVES (Lincoln) showed a myomatous uterus with the deflected cavity resulting; and Dr. F. H. JACOB showed microscopic specimens of *Diplococcus intracellularis* from a case of epidemic cerebro-spinal meningitis.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.—At a meeting in Manchester on April 23rd, Dr. J. W. MARTIN (Sheffield), President, in the chair, Dr. H. BRIGGS (Liverpool) showed two specimens of *Haematometra* removed by the abdominal route. In each case the retention of menstrual fluid was due to congenital atresia of the cervix. The patients were unmarried women, aged 32 and 35 respectively. Microscopic examination of the uterine wall showed a great excess of fibrous tissue and an absence of the glands of the endometrium. Dr. A. DONALD (Manchester) read notes of a case of bilateral *Abscess of the uterine appendages* occurring during pregnancy. Three weeks after spontaneous premature delivery each abscess was drained extraperitoneally through an anterior colpotomy incision. A marked improvement in the patient's condition immediately followed, but two weeks later symptoms of acute peritonitis appeared. On opening the abdomen a ruptured pyosalpinx was found and removed. Since then the patient had made a steady recovery. Dr. J. H. WILLETT (Liverpool) showed the specimen from a case of *Caesarean section* and abdominal hysterectomy for carcinoma of the cervix complicating a seven and a half months pregnancy. The patient was a multipara, aged 34. Irregular haemorrhage commenced at the end of the first month; later the discharge became offensive. The vagina was divided between clamps, but no attempt was made to excise the pelvic connective tissue. No enlarged glands were found. The mother made a good recovery, but the infant died when about 4 weeks old. Dr. W. BLAIR BELL (Liverpool) read the notes of a case of acute *Puerperal sepsis* with thrombosis of the ovarian veins, which were ligatured and excised without success. Death occurred sixteen hours after the operation. The details of a very complete bacteriological study of the case were given. Dr. Bell was of opinion that when septic thrombosis of the ovarian veins is diagnosed immediate ligation and excision should be practised. The President and Drs. BRIGGS, DONALD, and LEE argued that the operation in such cases was useless. Dr. A. DONALD (Manchester) read a note on the use of gauze drainage in certain cases of puerperal sapraemia in which retention of lochia occurs from sharp antelexion of the uterus with sagging of the body. Toxaemic symptoms due to decomposition generally arose, he said, on the eighth or ninth day or soon after. Immediate improvement followed intrauterine douching, but renewal of the retention and of the symptoms was apt to occur. This was best avoided by the use of a gauze drain.

A REPORT by Mr. Warburton, F.Z.S., to the Local Government Board (New Series, No. 2, price 2d.), on a preliminary investigation on flock as a possible distributor of vermin, contains some information on the life-history of the body louse. It appears that not only the eggs but the lice themselves may pass through a flock-making machine without being crushed; the lice, however, are incapable of surviving more than three or four days without food, so that it is extremely unlikely that any of them would be alive when the flock was converted into bedding. The eggs, however, may take any period from eight days to five weeks to hatch, so that it is possible that living eggs might be present in flock bedding. The period of development from larva to imago is eleven days, after which there is a non-functional mature condition lasting four days. Adult life has been shown to endure for three weeks in the male and four in the female.

Reviews.

IMMUNITY.

For several years Sir A. E. WRIGHT's work on vaccine therapy and the significance of the opsonic index has been the subject of much discussion and no little divergence of opinion. The title of his new work, *Studies on Immunization*,¹ led us to hope that here the author would clear up many difficulties which beset the subject by giving a full exposition of his present standpoint and meeting, fairly and squarely, the criticisms which many pathologists of repute have raised. We find, however, that the volume is less helpful than might be expected. It is a reprint of various papers published during the last twelve years, partly by Sir A. E. Wright, partly as the conjoint work of Sir A. E. Wright and various other pathologists, and, in a few cases, by Drs. Bulloch, Atkin, Western, and Keith. Only three of the papers have been revised; the rest have been reprinted without any change except the omission of detailed descriptions of technique. In expressing disappointment with this mode of presenting the subject we cannot do better than quote Sir A. E. Wright's own words. He admits that "no collection of separate papers, such as is here presented, can possess such an organic unity in its structural design as would enable the reader who is referring to the book to place his finger upon the place where the particular point he is in search of might properly be found." Careful examination of the contents of the book proves that the author's criticism is thoroughly justifiable. For this candidly admitted defect he has endeavoured to make amends by elaborating the index, which he describes as "something in the nature of an orderly synopsis." He relies on his index also as a means of silencing adverse criticism. "I have also found in the index an agency through which replies might be furnished to certain of my critics. By making use of the index as a finger-post, I have pointed these critics in each case to an impersonal reply inscribed in the text. It is a method of rejoinder which I would venture, with all submission, to recommend." This is a brilliant suggestion, revealing vistas of advance in medical literature. The *British Medical Journal*, for example, is constantly engaged in combating statements in conflict with its opinions previously enunciated; but it has not hitherto assumed that the task of direct comment upon these matters is rendered superfluous by the publication of a copious index every six months. The moment when Sir A. E. Wright has proved that adverse critics can be silenced by the publication of an index will be awaited on the tip-toe of eager expectation. The reprints in the present volume do not call for renewed criticism, but they form a very useful collection of important articles on agglutinins, bactericidins, opsonins, and the methods and results of vaccine therapy.

Studies on Immunity, by Professor MUIR of Glasgow, with the collaboration of Drs. BROWNING, FERGUSON, and MARTIN,² is another volume of reprints. In it are reproduced, with some alterations and a few addenda, articles which have been published in various journals during the years 1903-9. They deal with the properties of haemolytic serums, the deviation of complement, and the antibacterial properties of serum. To the select circle of pathologists who devote themselves to the study of immunity Professor Muir's investigations are already well known, but it will doubtless be a convenience to these workers to obtain in one volume a variety of important articles which have hitherto been distributed over various journals. It is disappointing to find that Professor Muir has not endeavoured to appeal to a wider audience. His reputation as an authority on immunity research stands so high that a general survey from his pen of the present position of the science of immunity would be accepted as reliable by a very large circle of medical readers, and would help to remove some of the confusion to which conflicting statements about the subject have given rise. Unfortunately, as the author

¹ *Studies on Immunization*. By Sir A. E. Wright, M.D., F.R.S. London: Archibald Constable and Co., Ltd. 1909. (Med. 8vo, pp. 506, 16s.)

² *Oxford Medical Publications. Studies on Immunity*. By Robert Muir, M.A., M.D., in collaboration with Drs. C. H. Browning, A. R. Ferguson, and W. R. M. Martin. London: Henry Frowde, and Hodder and Stoughton. 1909. (Demy 8vo, pp. 228, 7s. 6d.)

frankly confesses, in the present volume "no attempt is made to give a historical review of the whole subject; due reference is, however, given to the results of others, available at the time of first publication, in connexion with the various subjects discussed." That saving clause, "available at the time of first publication," provokes us to raise a word of protest. The volume before us is published and advertised as a new book, bearing the date 1909. Then why does it not undertake to give due reference to all such results as were available up to the date of going to press? The time of first publication of the articles now reprinted is a matter of relatively little importance to the reader; but recent contributions to the science of immunity are numerous, and the reader has a right to expect that what is published now should be thoroughly brought up to date. Among the many interesting essays in the volume special attention may be called to that devoted to the scientific principles underlying opsonic action—a subject where we are always glad to have the trustworthy guidance of Professor Muir's sound observation and shrewd criticism. His general conclusion is that in the case of normal serums the opsonic effect is usually due to the labile non-specific complement, which may act with or without a natural immune body. In this respect he finds a close parallelism between opsonic and normal bactericidal action. In the case of immune serums, he observes, the opsonic effect may be increased by immune bodies leading to the union of more complement; but there is, in addition, the formation of immune opsonin (bacterio-tropin), which produces an opsonic effect by itself, and possesses the constitution of an agglutinin.

TROPICAL HYGIENE AND PATHOLOGY.

Books dealing with questions of hygiene as applied to the tropics are not very common, so the volume entitled *The Principles of Hygiene as Applied to Tropical and Sub-tropical Climates*,³ by Professor SIMPSON, is very welcome. Many students of tropical medicine have listened to these lectures, delivered by the author at the London School of Tropical Medicine, and many have no doubt often wondered why they have never been put into book form. The treatise is a good one, and will supply a long-felt want. Its pages are filled with personal observations. Water supplies, purification and examination of water, take up four chapters, food and food supplies three, conservation or collection and sewage two; soil and drainage. Hygiene in relation to streets, houses, etc.; sanitation of gaols, communicable diseases, and village and town sanitation in relation to malaria and other diseases caused by mosquitos occupy each one. There is little to criticize adversely in the book. Perhaps more might have been made of the chapter dealing with diseases spread by mosquitos. Here there is no very definite distinction drawn between domestic or house and wild or forest and jungle mosquitos. As the means required to deal with these different varieties differs very greatly more detail would have been useful. The question also of the prevention of malaria in campaigns, and for single individuals travelling through the bush and living in tents, might well have had a chapter to itself. Still, space must be considered, and no doubt Professor Simpson had this in his mind when he refrained from a fuller discussion of the malarial question. The work is dedicated to Sir Patrick Manson—a fitting compliment. The book, which is uniform in style and shape with the *Studies in Laboratory Work* by Daniels and Stanton, and therefore of convenient size, ought to meet immediate success, and have a long life before it.

An epitome of exotic pathology⁴ is a recent addition to the series published under the general title *Précis Médicines*. It is written by Professor JEANSELME and Dr. E. RIST, of Paris, and the type, appearance, and general style of the

book at once recall the well-known manual on tropical diseases by Manson; the resemblance is enhanced by the presence in it of several diagrams and figures borrowed from the latter. Judging it from this standard it is seen to be fuller, diseases such as typhoid bilieuse (infectious jaundice), syphilis, intoxications, illnesses produced by climate, ocular manifestations, and cosmopolitan maladies such as pneumonia, rheumatism, tetanus, and tubercle, being included. Where it falls short of the standard is that its authors do not seem to have the personal acquaintance with many of the diseases which is necessary to enable them to write clearly about them. Such being the case, the information must be second-hand, and being often collected irregularly and not sifted thoroughly the summary becomes uninteresting, especially to those who know the subject and have worked at it. Examples are numerous throughout the book, but reference need be made only to kala-azar, beri-beri, yellow fever, sleeping sickness, and filariasis. The chapter on sleeping sickness (human trypanosomiasis) is specially poor; the clinical description of the disease is muddled, the blood changes find a minute place in the pathological anatomy, and the lymphatic changes are dotted into the diagnosis. The importance attached by Todd to enlarged glands as a means of diagnosis is condemned by the work of the recent French Commission; but if the authors had read the first clinical reports of the Royal Society's Commission to Uganda, they would have seen that this had already been demonstrated years before. There is a distinct tendency throughout the book to utilize recent French work to the exclusion of work done long ago in other countries; and though this can easily be understood, nevertheless it spoils the value of the book. In the chapter on *Schistosomum japonicum* the name of Catto does not once appear; as he discovered this parasite independently and was the first to bring the subject prominently before helminthologists in Europe, this is, to say the least of it, strange. Amongst the points worthy of notice in the book are the discussions on the differences between syphilis and yaws and between amoebic and bacillary dysentery. The authors, in accord with the general opinion of the present day, agree that these differences are real. After what has been said above, one would expect a very prejudiced or French account of sprue, and that is what we find. The disease is termed the chronic diarrhoea of warm climates, or Cochin China diarrhoea—both equally bad terms—and the account of the disease is very poor. The book, then, to sum it up, is written from a one-sided point of view, and though it is useful at times to see how others look at things, it cannot be recommended—certainly not to students in this country.

The pamphlet entitled *Malarial Fevers*, and described as "drawn up for the use of assistant surgeons, hospital assistants, and students," by Major S. P. JAMES, I.M.S.,⁵ admirably answers its purpose. Though couched in simple language the text is quite full enough to give a very good idea of the subject; scientific terms are carefully explained. In the part dealing with the diagnosis of malarial fevers (p. 65) no reference is made to the value, as a means of differentiating many of the different fevers, of blood counts—a method which should be within the reach of those for whom the book is intended; the estimation especially of the leucocytes in many cases at once makes the diagnosis clear. If leucocyte counts were more frequently made in ordinary home medicine as well as in tropical medicine fewer mistaken diagnoses would be made. A very useful chapter of the book is that on treatment and prevention. Properly applied treatment certainly has an extraordinary effect in reducing the mortality from malaria and has robbed the disease of many of its terrors. Prevention, however, is better than cure, and Major James's students will find this fully discussed as well. Short and to the point are the characteristics of this eminently useful and practical pamphlet.

Calcutta: Superintendent Government Printing, India. 1908. (Cm. 4to pp. 34.)

THE ACUTE SPECIFIC FEVERS.

To devote a volume of a hundred and fifty pages and nearly as many illustrations to the diagnosis of a single disease, suggests a superfluity of words and work. We cannot, however, accuse Drs. RICKETTS and BYLES of verbosity or waste of energy in their book on *The Diagnosis of Small-pox*.⁶ If there is a disease which is worthy of the distinction we have mentioned, it is small-pox. This loathsome, fatal, and highly-infectious disorder is never at the present day so continuously our companion as to accustom us even to its usual guises, yet its visits are sufficiently frequent to render us all liable to receive one, and evil is the day on which we fail to recognize the dangerous visitor. The most interesting and important portion of the book is contained in the second, third, and fourth chapters, which deal with the distribution of the eruption. Dr. Ricketts has previously told us that evidence from the distribution of the pocks is more valuable in diagnosis than evidence from their character. In these chapters, the theme that irritation of the skin largely determines the distribution is worked out in detail, and with such a wealth of illustration, verbal and pictorial, that the reader can hardly fail to carry the essential points in his memory. Another excellent chapter is the fifteenth, in which the differential diagnosis between small-pox and chicken-pox is discussed. The importance of this chapter will be recognized from the statement made on page 1, that "two-thirds of the errors in the diagnosis of small-pox arise from its confusion with chicken-pox." All the common, and most of the rare, diseases that are confounded with small-pox are amply reviewed, but we miss references to purpura haemorrhagica and acne varioliformis, diseases for which we have known small-pox to be mistaken with disastrous results. To discuss the pathology of the disease is outside the author's intention, but an expression here and there, hinting at a pathological hypothesis which we believe to be new, serves to whet our desire to have from Dr. Ricketts's pen a full exposition of his ideas on this subject. We are the more inclined to urge him to this task because it is some time since we have read a work by a new medical writer composed in a style so pleasant as the one under review. Of Dr. Byles's share of the work we have nothing but praise. The half-tone reproductions in black and white of his photographs, many of them stereoscopic, are a sufficient refutation of statements that have been made by some writers that photographs are of little, if any, value in the portraiture of cutaneous eruptions. The coloured plates, produced from triple negatives taken directly from life, are admirable, and are a feature of the book. Altogether this volume is one which, in places and times when small-pox is likely to be rife, no medical man who is unacquainted with the disease can afford to be without.

It is well known to those whose experience of the acute infectious diseases is at all extensive that during their course rashes, other than those which are distinctive of these diseases, not infrequently occur. They have been called by English writers "septic," "secondary," or "accidental," but little has been written about them either in this country or abroad, and that only in a desultory way. Dr. MARCEL POISOT has done good service, therefore, in collecting together in his book on erythematous eruptions of a severe nature⁷ the facts and hypotheses relating to them. The rashes in question are of various kinds; the commonest is a morbilliform erythema most marked upon, if not confined to, the extremities, but they may be scarlatiniform, urticarial, vesicular, purpuric, or varieties of erythema multiforme. Perhaps they are met with most commonly in scarlet fever, especially in scarlatina anginosa, but they are not rare in diphtheria and enteric fever. They have also been observed in outbreaks of sore throat due to milk. Amongst the various questions discussed by Dr. Poisot, the most interesting are those relating to the con-

tagiousness and pathogeny of the "syndrome," which usually consists of rash, vomiting and diarrhoea, ulceration of the lips, prostration, and a fall of temperature. The cases are sometimes observed to occur in small groups, a fact which suggests the infection of one patient by another. But the author easily disposes of this hypothesis. The pathogeny is by no means clear. Various writers have from time to time suggested that these cases are aberrant forms of the common infectious diseases, or drug rashes, or due to different bacteria or their toxins, especially streptococci, the *Enterococcus proteiformis* of Thierlein, the *Bacillus typhosus*, and the *Bacillus coli*. But here again Dr. Poisot has no difficulty in showing that the evidence in favour of these agents is by no means strong. The view of the cause of the syndrome favoured by the author is that which attributes it to insufficiency of action of the large glands, especially the liver and the kidneys, and that this insufficiency is dependent upon degenerative changes in the parenchyma produced by bacterial toxins. We doubt, however, whether this view explains all the cases—for instance, those in which the syndrome makes its appearance during the course of a slight attack of an infectious disease. The more probable view seems to be that the symptoms are produced in much the same way as are those of the so-called "serum disease," possibly by the circulation in the blood of some toxic body formed by the combination of the original foreign substance and its antibody. But we confess that this view is, perhaps, more speculative than those propounded by Dr. Poisot.

We regret not to be able to say very much in favour of Dr. R. W. MARSDEN'S *Practical Textbook on Infectious Diseases*.⁸ It seems to us neither to justify its title nor to come up to the reputation of its author. No one can accuse Dr. Marsden of lack of experience, and we can only suppose that he has been hampered in the production of this volume by want of time for revision and verification, and of space for explanation. Pathological matters are inadequately treated, and on the practical side lumbar puncture and intravenous injection are no more than mentioned, Widal's reaction is inadequately described, and methods of disinfection are not discussed. Even if we admit with the author that the larger books and the articles in the various systems of medicine are too full of detail to be useful to busy men except for reference, and that there is room for a small textbook which shall "briefly outline our newer conceptions of these diseases," we do not think that the volume before us carries out his idea of what such a work should be. Even for an outline it is too sketchy and indefinite.

Dr. LANGFELD'S *Infectious and Parasitic Diseases*⁹ was primarily intended for nurses, but on the advice of his friends he incorporated additional matter with the object of enhancing the value of the book for physicians and students of medicine. Apparently the account of the malarial parasite's life-history and the chapter on "the portals of entry and avenues of exit of micro-organisms in the various diseases" are examples of this desire to cater for the latter class of reader. The result is an unfortunate jumble. The introduction of a few highly technical details cannot possibly raise the book to the standard of the average textbook designed for medical students, whilst these matters are quite outside the sphere of a hospital nurse, and, from the nurse's standpoint, the less technical matter falls far below the standard of nurses' handbooks written by many English authors. The composition is slovenly, and there is far too much padding. A few examples may be quoted at random. "In this matter of the exit of micro-organisms from the body in disease we have the key to the happiness of families, the prosperity of nations, and to victory in wars." The common flea is described as "a minute red or dark-brown insect which is only parasitic upon man in countries where it is present in

⁶ *The Diagnosis of Small-pox*. By T. F. Ricketts, M.D., B.Sc., M.R.C.P. Lond., Medical Superintendent of the Small-pox Hospitals of the Metropolitan Asylums Board: illustrated from Photographs by J. B. Byles, M.B., B.C. Cantab., F.R.C.S. Eng., Senior Assistant Medical Officer of the Small-pox Hospitals. London: Cassell and Company, 1908. (Med. Rev. pp. 170, 21s.)

⁸ *A Practical Textbook on Infectious Diseases*. By R. W. Marsden, M.D., M.R.C.P., formerly Medical Superintendent, Mumps Fever Hospital. With a chapter on Puerperal Septic Disease by A. Knyvett Gordon, M.A., M.B., Medical Superintendent, Mumps Fever Hospital, Manchester. The University Press, 1908. (Cr. 8vo, pp. 324, 5s.)

⁹ *Introduction to Infectious and Parasitic Diseases*. By Millard Langfeld, A.B., M.B., Professor of Bacteriology, etc., Omaha, U.S.A. London: Rebusan Limited, 1908. (Post 8vo, pp. 276; 33 illustrations, 5s. 6d.)

great numbers. It is particularly troublesome in hot countries." "With one exception, that is, in consumption, the sputum is chiefly dangerous to those immediately surrounding the patient." "The modern method of food distribution is a marvellous development, that is comparable to other inventions of the 19th century." The author says in the preface to his book that most of it was written "during moments snatched here and there between urgent duties"; it certainly bears the impress of hasty writing, and we cannot compare it favourably with many books upon which more time and labour have been expended.

DISEASE AND INJURIES OF JOINTS.

In this recent work on *Injuries and Diseases of the Knee-joint*¹⁰ Sir WILLIAM BENNETT has dealt with his subject in the form, not of a systematic treatise, but of a series of clinical essays, devoted almost exclusively to questions of clinical and practical import. In this way some of the results of long and wide experience and of skilled observation are given to those who, though in active surgical practice, would be ready to welcome information which the eminent author himself, as he acknowledges in his preface, would have been glad to have had at his disposal some years ago. This information, it need hardly be stated, is very clear and definite, and is given in a style well adapted to afford sound and, in many respects, quite fresh instruction to practical men. In the fifteen chapters here devoted to a long list of traumatic and pathological conditions involving a large and complex joint the practitioner will find much help when confronted with doubtful questions as to the nature and the proper treatment of a perplexing case. Many useful hints are given on points of diagnosis; attention is directed to what seems to have been hitherto unrecognized, though, as Sir William Bennett shows, they are not infrequent, forms of articular effusion, and among other important suggestions on treatment objection is raised to indiscriminate use of retentive appliances in cases of injured or diseased knee. An introductory chapter on certain points in the normal anatomy of the knee, viewed from a clinical standpoint, is followed by a full and practical review of the different forms of intra-articular effusion. In these, and especially in two subsequent chapters on slipped cartilage, the author gives a lucid and helpful analysis of diagnostic signs, and very judicious teaching on the favourable and the doubtful conditions of active surgical treatment. Here and there the reader is reminded of the value of the Roentgen rays in diagnosis, even in cases in which such method of investigation is commonly thought to be futile; of the evils of prolonged immobilization in many forms of injury and disease; and the necessity before opening the affected joint for exploratory or therapeutical purposes, of inquiry into the general condition of the patient. The clinical teaching on most of the subjects is helped and not, as so often occurs, unduly encumbered by clinical records. A glance at the titles of the concluding chapters of this instructive book will show that Sir William Bennett has presented a full and comprehensive review of the modern surgery of the knee. In the chapter on injuries in and about this joint he deals with the operative treatment of fracture of the patella, and in the closing pages expresses a favourable though not unqualified, appreciation of Bier's method of induced hyperaemia, which he regards as being in certain cases a valuable adjunct to other methods of treatment.

THE seventh fasciculus of the *Nouveau Traité de Chirurgie* of Professors LE DENTU and DELBET is entitled *Maladies des Articulations*, and is written by Professor MAULAIRE and Dr. DUJARIER.¹¹ In this category injuries which have been already dealt with in the fifth fasciculus are not included, and although a great part of the seventh is devoted to tubercle, the whole of the eighth also, by Dr. Ganggolph, will deal with tuberculous arthritis. In this seventh fasciculus Professor Maulaire is responsible

for the articles upon infectious and non-infectious inflammatory arthritis and on ankylosis and articular tumours, and Dr. Dujarier for those on foreign bodies, arthritis deformans, and arthropathies of nervous origin. The authors take a broad view of their subject and discuss its many problems in pathology and treatment with moderation and judgement. While they hardly lay stress enough on the importance of conservative treatment, especially of tuberculous disease, they are not members of the impatient forward school, whose motto might be "Operate! Operate! and again Operate!" No such appalling list of (so-called) excisions of the hip as that recorded by König is to be found here, but at the same time hardly enough consideration is given to the ambulant treatment of tuberculous joints of the lower extremity, so ably advocated by H. O. Thomas and in America. The work of Thomas is so generally ignored on the continent of Europe, that we are not surprised to find no mention of it in a French treatise. No descriptions of operations or of apparatus are given, except in the chapter on ankylosis, possibly because such matters are to be treated in other volumes of the work. Generally speaking, more consideration and space is devoted to classification and etiology than to treatment. Professor Maulaire admits two forms of articular tuberculous arthritis, typical and atypical. The latter class he divides again into six other forms, and the last of these, the synovial form, is again subdivided into seven varieties. This classification is made from an anatomical point of view. From a clinical standpoint, the abnormal class is divided into eight varieties, several of which are subdivided again. Four forms of tuberculous rheumatoid arthritis are mentioned; this is a disease of which very little is heard in this country, and its claims to be considered a pathological entity are hardly admitted by British pathologists. "Growing pains," Professor Maulaire thinks, are an indication of bone or joint tuberculosis or osteomyelitis. Many pediatricians think that they are evidence of rheumatism. As to treatment, Professor Maulaire's personal experience of Bier's hyperaemic method has not been favourable. Immobilization is the most important principle. Injections of zinc chloride into the tissues around the joint, as recommended by Lannelongue, have, says Professor Maulaire, given remarkable results, especially in children. Failing expectant treatment, arthrotomy, arthrectomy, excision, and, as a last resort, amputation are to be the rule; but excision should be seldom done unless previous arthrectomies have failed to arrest the disease. The sections on syphilis and gonorrheal affections of joints are adequate, but here again we venture to think that there is an over-refinement of classification. Loose bodies in joints and their treatment are well described by Dr. Dujarier, but we think a little space might well have been spared to discuss the best incisions for their removal. Subluxations of the semilunar cartilages are not included in this section. The same writer treats of arthritis deformans, without finding it necessary to mention the name of Paget. He mercifully does not try to emulate Pribram, who named twenty-one varieties of Charcot's chronic rheumatism. The fasciculus concludes with an interesting account of arthropathies of nervous origin, which, however, offer little scope for surgery except orthopaedic; but this kind of palliative treatment is almost ignored by the author. For hysterical arthropathies massage in an early stage, and later anaesthesia, general or spinal, sham operations, and electricity, are recommended. Pilgrimages to Lourdes or some other shrines of healing are also, it is said, to be tried; but these are surely outside the domain of surgery! Like the other parts of the *Traité*, this fasciculus is printed in clear type on good paper, and is well illustrated, but the French compositor is often unhappy in his rendering of foreign proper names.

FRACTURES OF THE UPPER EXTREMITY.

DR. BORCHGREVINK of Christiania relates in his book on ambulatory traction treatment¹² some experiences which led him to abandon the use of fixation by means of plaster.

¹⁰ *Injuries and Diseases of the Knee-joint*, Considered from a Clinical Aspect. By Sir W. H. Bennett, K.C.V.O., F.R.C.S., Consulting Surgeon to St. George's Hospital, etc. London: James Nisbet and Co., Ltd. 1909. (8r. 8vo, pp. 256; 31 illustrations, 5s.)

of Paris, and to devise the splints which he here describes for the treatment of fractures and some other injuries of the upper limb. Fourteen years' surgical practice in Christiania have offered great opportunities, of which the author has made the most. Not only are injuries common in the factories of that city, but the sport of skiing, which is popular with persons of all ages, produces its quota of accidents. One of the chief difficulties in applying traction in fractures of the arm or of the forearm (when the latter is extended) has been the want of a suitable point of counter-extension. The axilla not only bears pressure badly, but is also an unstable point, varying as the arm is abducted or brought to the side. Yet it is the only available point for direct counter-extension. To meet the difficulty, Dr. Borchgrevink makes the splint end above in a loop or a U-shaped fork which lies round the armhole of the waistcoat or bodice, to which it is fastened. To prevent this garment being pushed up by the splint, it in turn is held down by an elastic perineal band. Such a method of counter-extension is obviously of no use when the direction of traction must be at an angle to the axis of the upper arm, as in many forms of injury it should be. In that case the bearing is taken on the front of the arm above the elbow-joint.

In all cases the lower end of the splint is provided with a pulley on a stem, which projects beyond the end of the wooden splint. Adhesive plaster is applied to the part below the fracture with great care, and by means of a stirrup of plaster and a cord round the pulley, leading to a piece of rubber tubing at the back of the splint, any desired amount of traction can be made. The limb is otherwise only very loosely fastened to the splint, so as to avoid constriction of the soft parts. There are four forms of this splint: for the upper arm, forearm, hand and fingers, and a combined splint, which may be either angular or straight. All these are fully described, as is also the means of improving them.

The advantages claimed for traction are that it overcomes the elastic contraction of the muscles, diminishes secondary reaction and pain in a marked degree, and corrects displacement better than any rigid method. The cases related and the Roentgen pictures reproduced in this book bear out these claims. As to callus formation, the author agrees with Bardenheuer that in an ideal union by first intention no callus is thrown out, and that callus is analogous to the fibrous tissue which results from suppuration in soft parts. Lucas-Championnière, on the other hand, claims the free production of callus as one of the merits of his method. Bardenheuer quotes 10,000 fractures of shafts of bones, and Borchgrevink 500 cases of fractures of the upper extremity without one case of pseudarthrosis. Besides fractures, this book treats of sprains, in which the effect of traction in relieving pain and preventing stiffness is as recorded most striking. The chapter on contracture and ankylosis is excellent. The author has not found electricity and massage of great value, and he cites the records of accident insurance in his support. He says: "The effort of will that brings a muscle into active contraction is better than all the electrical currents, and use maintains and restores muscle power better than any massage. Passive movements will overcome contracted antagonists, but the ground thus gained must be occupied by active movements, or it will speedily be lost once more." His rhymed motto may be rendered roughly, "Apparatus less, More success."

DIAGNOSIS AND TREATMENT OF MELANCHOLIA.

A PAMPHLET on the recognition and treatment of melancholia in practice, by Professor ZIEHEN of Berlin, formerly of Jena, was published in Parts II and III, vol. i, of the *Sammlung Zwangloser Abhandlungen aus dem Gebiete der Nerven- und Geisteskrankheiten*, edited by Professor Hoche of Freiburg. This small monograph is now deservedly in its second edition,¹² and, as one would expect from its source, forms a lucid, instructive, and practical guide to the diagnosis and treatment of this psychosis. Right or wrong in his conceptions, Professor Ziehen is always clear in his views and their expression, leaving no possibility of doubt as to his meaning. Melancholia is defined as a psychosis whose chief symptoms are

(1) a primary, continued, motiveless, or insufficiently motivated depression, and (2) a primary retardation of the course of ideal presentations or mental inhibition. The first symptom is never wanting, but the second may be transitory in certain circumstances. By "primary" it is meant that the depression or the inhibition, as the case may be, is not the result of other psychopathic symptoms—for example, is not, in the case of depression, the result of delusions, say of persecution; and in the case of inhibition is not produced by "fascinating" or engrossing hallucinations. Further, in melancholia the depression and inhibition are mutually co-ordinated, waxing and waning synchronously, even if, as a rule, the depression appears first and disappears last. Although Professor Ziehen's definition of melancholia would exclude many cases so classed in this country—melancholia forming only 16.4 per cent. of the female and 5.3 per cent. of the male admissions to the Jena asylum in the years 1886-1894—he does not agree with the growing Continental opinion that the term "melancholia" should be restricted to the depression of senile involution, and, indeed, shows that it may occur at any age, cases of true melancholia even in childhood having come under his observation. For the author's views as to the principal etiological factors of melancholia—its differential diagnosis, course, termination, and treatment—we would warmly commend this brief and admirable study to our readers. We may say, however, that Professor Ziehen considers that with proper asylum treatment over 90 per cent. of melancholics should recover, though this is without taking into consideration relapses which occurred in over 22 per cent. of his cases. Termination in secondary dementia is, he states, very uncommon, and occurs solely in the melancholia conditioned by arterio-sclerosis.

TREATMENT BY HYPERAEMIA.

THE second German edition of Professor BIER on hyperaemia as a remedy was reviewed two years ago. The American translation by Dr. BLECH of Chicago is made from the sixth German edition,¹⁴ a sufficiently remarkable testimony to the interest taken by Professor Bier's countrymen in the methods he has introduced into practice. A good many surgeons in this country have no doubt used the very simple means recommended, but they are not as popular or as widely known as they should be, for, although a good account of the method was published in English last year by Drs. Willy Meyer and Victor Schmieden, no translation of Professor Bier's book has hitherto appeared in English, and we hope Dr. Blech's translation will be widely read. The present volume contains only a few additional pages, including chapters upon the treatment of teno-synovitis crepitans and keloids. The hot-air apparatus, which Professor Bier regards as a very important part of his method, is very inexpensive, and in his opinion quite as efficient as the appliances for radiant heat, the use of which can only be obtained in large towns or public institutions or health resorts, while the very simple and economical method of treating tuberculous joints by elastic bandages is one which any practitioner, however situated, can carry out. The translation is in the theoretical parts rather obscure, owing probably to Dr. Blech being a German, and being therefore accustomed to think in the idiom in which the book is written, so that in this respect it is somewhat difficult for English readers to follow. It is strange to see in a book published in English the reference to John Hunter's work on *Inflammation* given only in the German translation published at Leipzig in 1797, four years after Hunter's death. We note "recocer" for "recur" (p. 10), and on p. 225 there is the word "doby," which at first looked like an American neologism of unknown meaning, but after consideration resolved itself into a mistake of the printer for "body."

THE ORIGIN OF PIGMENT.

WE have received a monograph by Dr. E. MEIROWSEY, of Breslau, on the origin of the melanotic pigment of the skin and eye,¹⁵ which contains an account of an interesting and apparently very accurate series of researches on the

¹⁴ *Bier's Textbook of Hyperaemia*. By Professor Dr. A. Bier. Translated from the German edition by Dr. G. M. Blech. London: Rebusan Ltd. 1909. (Demy 8vo. pp. 455. 12s. 6d.)

¹⁵ *Ueber den Ursprung des Melanotischen Pigments der Haut und des Auges*. By Dr. E. Meirowsky. Leipzig: Dr. W. Klinkhardt. 1909. (Roy. 8vo. pp. 122. plates 8. M. 75.)

¹² *Die Erkennung und Behandlung der Melancholie in der Praxis*. By Gen.-Med.-Rat. Prof. Dr. Th. Ziehen. 2nd edition. Halle-a.-S.: Carl Neubert. 1907. (Med. 8vo. pp. 67. M. 2.)

development of pigment after exposure of the skin to the Finson light. Pieces of skin were excised and submitted to microscopical examination. Coloured plates are given showing melanoblasts—branching connective tissue cells loaded with pigments—creeping in between the deeper cell layers of the epidermis, the cells of the epidermis loaded with pigment, pigment granules in the intercellular lymph spaces, and pigment in process of formation from the nuclear substance of the cells. The author adduces strong proof of his contention that the pigment not only arises from the melanoblasts of the cutis, but is also formed *de novo* in the epidermic cells; that it arises from the chromatic substance of the nuclei; that nuclear growth and activity precedes the development of the pigment; that a substance is formed in the nuclei which stains red with pyronin, and that this substance escapes from the nuclear plasma into the cytoplasm and finally becomes melanin; finally that two chemical processes are concerned, one, an autolytic process resulting in the setting free of the tyrosin group from the protein complex, and the other, the action of a ferment, tyrosinase, which changes tyrosin into melanin. This ferment is found widely spread in both the plant and animal world. The author gives an excellent account of the history of his subject, and adds a full list of references to the literature.

BRITISH JOURNAL OF DERMATOLOGY, 1909, 1, 1.

NOTE.—See also THE LANCET, 1909, 1, 1.

NOTES ON BOOKS.

IN his *Radiant Light and Heat* Dr. W. B. SNOW, of New York, has brought together some useful information regarding the practical methods of applying these agents and their value, principally in dermatology. He lays particular stress upon the effectiveness of combining two or more agents in physical therapeutics, and to this end he offsets the inhibitory action of somewhat massive doses of the Roentgen ray by means of the stimulating effects of radiant light or the static-brush discharge, thereby, he says, avoiding x-ray dermatitis. In a separate section he deals conservatively with the therapeutic possibilities of convective moist and dry heat in infectious inflammations and (when associated with other measures) in defective metabolism.

The twenty-fourth volume of the *Transactions of the American Climatological Association*¹ covers the proceedings of this body at its meeting in Boston in 1908, and is conspicuous for the number of papers devoted to a consideration of the administrative control of tuberculosis and its treatment by tuberculin in individuals. Another series of excellent papers deals with cardiac disease, one of them being a summary of a careful investigation into the question of whether the prevalence of diseases of the heart is increasing in the United States. The conclusion drawn is that the death-rate from cardiac disease is rising, in spite of the fact that the general rate shows a tendency to fall. The primary cause of this inconsistency is held to be the pressure at which all classes in the United States nowadays have to live, whether they inhabit great cities or rural districts, but the explanation does not seem very satisfactory.

MEDICINAL AND DIETETIC PREPARATIONS.

Caffeine-reduced Coffee.

IDIOSYNCRASIES with regard to coffee and tea are, as is well known, very common; there are people who, if they take coffee in the evening, cannot sleep well, others who suffer in a similar way after tea, and others who are equally unsuited to both beverages. These symptoms are no doubt due to caffeine or theine respectively. In other persons, again, coffee produces palpitation or other symptoms of cardiac discomfort, an effect from which tea appears to be more or less exempt. Our attention has recently been drawn to a coffee for which it is claimed that the greater part of the caffeine has been extracted. Examination showed that this coffee, which is called the "Life-belt" coffee, and is sold by a company of that name having offices at 71, Pastcheap, London, E.C., contains only about one-tenth or a little more of the amount of caffeine ordinarily present. It can, we believe, be obtained either in the roasted bean or ground, and the beverage made from it does not, so far as we are able to

judge, differ in flavour from untreated coffee made in the same way. This coffee will no doubt commend itself to persons who enjoy the flavour of coffee but do not desire its stimulating effects, or fear to suffer from insomnia or cardiac disorder as a consequence of indulging in the beverage.

MEDICAL AND SURGICAL APPLIANCES.

A Radium Applicator.

MR. W. H. MARTINDALE, Ph.D., has devised at the request of a client a small radium applicator in the form of a square locket: it has a mica window which cuts off the alpha rays while allowing the others to pass. A square

shape has been chosen, since it presents an advantage over a circle, as the surface to be treated when extensive can be planned out and treated at intervals, area by area, without the risk of covering the same part twice or leaving parts untreated. Radium

bromide is spread in a thin film on the square surface, either pure or mixed with an inert salt to yield a definite activity in uranium units, so that the operator may know exactly what strength he is using on a given surface. The locket applicators are made with an area of 1, 2, or 3 sq. cm.; nine carat gold is employed, and the price is stated to be reasonable. The appliance can be obtained from Mr. W. Martindale, 10, New Cavendish Street, Portland Place, London, W.

DRUG TREATMENTS FOR INEBRIETY.

A SOMEWHAT frequent constituent of preparations for the treatment of inebriety is atropine, while other preparations contain one or more of the alkaloids belonging to the same group, usually known as the solanaceous alkaloids, from the fact that they are all derived from plants of the nat. ord. *Solanaceae*. These alkaloids possess strong resemblances in their chemical nature and in their pharmacological properties; the principal members of the group are:

Atropine, $C_{17}H_{27}NO_3$, obtained chiefly from *Atropa belladonna* and *Scopolia carniolica*.

Hyoscyamine, $C_{17}H_{27}NO_3$, obtained chiefly from *Hyoscyamus niger* and *Scopolia* species.

Hyosine, or scopolamine, $C_{17}H_{27}NO_3$, obtained chiefly from *Scopolia* species, *Hyoscyamus niger*, and *Datura alba*.

The two following were originally described as separate substances, but have more recently been shown to consist of mixtures:

Duboisine, obtained from *Duboisia myoporoides*, consists chiefly of hyoscyamine and hyosine.

Daturine, from *Datura stramonium*, consists chiefly of hyoscyamine, with a variable proportion of atropine.

A certain preparation for inebriety is said to contain "stramonine"; as no alkaloid has been described and characterized under this name, it is probably only a variant of daturine, which, as has been said, consists of a natural mixture of hyoscyamine and atropine.

To the above may be added the artificial alkaloid homatropine ($C_{16}H_{25}NO_3$), which has not been found in a plant, but is prepared synthetically; in chemical constitution it is mandelyl-tropine, atropine being tropyl-tropine.

The differences in the action of the four principal solanaceous alkaloids are briefly as follows:

Atropine has a stimulant action on the central nervous system, especially on the motor area; it depresses and in large doses paralyses the nerve endings of secretory glands, plain muscle, and the heart.

Hyoscyamine is intermediate in its action between atropine and hyosine; causes less stimulation of the central nervous system than atropine, and is a weaker sedative and hypnotic than hyosine. It has the same action peripherally as atropine but is twice as powerful.

Hyosine resembles atropine in its paralysing effect upon peripheral nerve endings, the action being quicker, more powerful, and less lasting. It does not possess the stimulating effect of atropine upon the brain; depression of the motor area is marked from the first.

Homatropine resembles atropine in its action but is less powerful.

THE UNIVERSITY OF SHEFFIELD.

OPENING OF NEW LIBRARY.

THE Prince and Princess of Wales visited Sheffield on April 26th to open the University Library, the erection of which has been rendered possible through the gift of a sum of £10,000 for the purpose by Mr. Edgar Allen.

The university buildings occupy the slope of a hill on the verge of Weston Park, and the library has been erected on the highest point of the site, so that in approaching the university from the higher ground it is the most conspicuous building, and adds a very dignified note to the general effect. It is octagonal in form, of red brick with stone mouldings, in an ornamented Tudor style. There is a central hall, in the middle of which is a carved oak octagonal counter for the accommodation of the librarians, who from this central point will command a view of the entire building. Around the hall are eight richly moulded stone arches, leading into reading rooms with bay windows, fitted with tables and bookshelves, while above is a gallery with a similar series of rooms. Accommodation is provided for a hundred readers.

Two considerations have influenced Mr. E. M. Gibbs,

F.R.I.B.A., the architect of the university, in designing the library on this plan; one is that by making this series of rooms the classification of books will be facilitated, and the other that it will be easier to obtain quiet. The rooms have shelving for 25,648 volumes, and beneath the central hall is a lofty stock-room with a capacity for 97,696 additional volumes, making a total of 123,344 volumes. At present the library contains about 22,000 volumes.

Mr. G. C. Moore Smith, who was honorary librarian from 1895 to 1907, prepared for the occasion an interesting description of the library, in the course of which he predicts that if the university continues to receive benefactions at the rate which has so far prevailed, the library will in twenty or thirty years be famous in the North of England, and one of the chief glories of Sheffield. It is pleasant to note that those who are forming the library have not limited their ambitions to purely utilitarian objects. The committee puts forward a statement containing a list of the English printed or English written books down to the year 1640, and of foreign printed books down to 1600 which are already in the library; the committee adds with pardonable pride that whereas in 1897 the library possessed 5 of the former and 37 of the latter class, it now owns 191 of the former and 212 of the latter; of this total of 403 early books only 114 have been purchased, and it is to be hoped that citizens of Sheffield and graduates of the university who may not be able to rival Mr. Edgar Allen's splendid generosity may yet, acting in the same spirit, enrich the library by gifts of volumes which it still requires.

The Prince and Princess of Wales, who arrived at Sheffield a little before 2, drove to the Town Hall, where they were received by the Lord Mayor, and presented with an address from the city, in which reference was made to the earlier visit of the Prince in 1895 to open

a new wing of the Royal Hospital, to the visit of Queen Victoria in 1897 to open the Town Hall, and to the visit of King Edward VII and Queen Alexandra to open the buildings of the university. The address went on to express the belief that the library would be of the greatest value to an institution of which the citizens of Sheffield are justly proud, for the university is already doing an immense amount of good in the higher education of the people of that great industrial centre.

The Prince, in his reply, expressed the special satisfaction with which he and the Princess had travelled to Sheffield to take part in the opening of the new library of the university, and the pleasure with which he learnt that the good results achieved by the university in the higher education of the people were thoroughly recognized by the citizens.

After lunching at the Town Hall the Prince and Princess proceeded to the university, where they were received by the Chancellor, the Duke of Norfolk, E. M., K. G., by the Pro-Chancellor, Alderman Franklin, and the Vice-Chancellor, Sir Charles Eliot; a procession was formed, and on reaching the Firth Hall the Chancellor made a number of presentations to the Prince and Princess. The Vice-Chancellor then read an address, in which the officers

of the university expressed the earnest hope and ambition that the Edgar Allen Library might worthily fulfil the purposes for which it had been erected, that all who taught and all who were taught in the university might find within its walls the means to acquire knowledge and the inspiration properly to use it.

The Prince of Wales, in the course of his reply, said that the great development of the university movement was

Photograph by]

THE NEW LIBRARY

To cut Pres

a remarkable feature in the march of education during the latter part of the nineteenth century. The important industrial centres now recognized that there were problems to be solved differing widely from those dealt with in the more ancient universities. Sheffield had been quick to see the necessity of adapting herself to the industrial needs of the people, and to realize that scientific and technical knowledge was indispensable to success in the strenuous commercial struggle amongst the nations of the West. Thanks to the liberality of the late Mr. Mark Firth, the college which bore his name was founded in 1879, and incorporated twenty-six years later with those other institutions which constituted the University of Sheffield, including among them schools of engineering and metallurgy which were famous throughout the land. A more important essential to a modern university than the addition about to be inaugurated, containing accommodation for 120,000 volumes, could not be imagined. He hoped that the shelves of the Edgar Allen Library would be stored with all standard and many rare works, which otherwise were beyond the reach of the individual student, thus furnishing him with an intellectual equipment which would help him to compete and triumph in the professional career to which he was called.

The Chancellor then conferred the honorary degree of Doctor of Letters on the Prince of Wales and Mr. Edgar Allen, and afterwards delivered a short address in which he thanked their Royal Highnesses for the interest they

had displayed in the university, and announced that Mr. Edgar Allen had presented £1,100 to a guild which has the charge of watching over the poor of Sheffield, had undertaken to give £5,000 to the Royal Infirmary on the condition that a ward or a wing in the institution should be called after the Prince, and £5,000 to the Royal Hospital on condition that a ward or wing should be called after the Princess.

Their Royal Highnesses then proceeded to the library, and Mr. Allen presented to the Prince a key, with which he opened the door. On entering the library the Bishop of Sheffield offered a brief dedicatory prayer, and the Prince declared the library open. Subsequently the royal party visited the physics laboratory under the guidance of Professor Hicks.

THE MILK PROBLEM IN AMERICA.

Dr. EASTWOOD's report to the Local Government Board on American methods of regulating and improving the milk supply¹ is introduced by a covering letter from Dr. Newsholme, Medical Officer to the Board, who, after describing the scope of the investigations with which Dr. Eastwood was entrusted, states that

The information collected by him and his personal comments thereon are interesting and instructive. They will be of value not only in relation to prospective legislation, but also as throwing light on administrative problems in this country.

The following is an outline of Dr. Eastwood's observations and recommendations.

BOVINE TUBERCULOSIS.

He has paid special attention to the methods adopted with a view to the eradication of bovine tuberculosis by the States of Wisconsin, Pennsylvania, Massachusetts, Minnesota, and New York. Whilst recognizing that the results obtained in some districts are encouraging, he considers that the general outlook for the country as a whole is not hopeful.

The disease is so widely disseminated, and the economic obstacles to its elimination are so excessively great, that it is impossible, even by a generous interpretation of the efforts which are being made, to put together tangible evidence of substantial success on the lines which have hitherto been followed. Tuberculosis progresses so insidiously, persists so long before manifesting its presence by physical signs, and has taken so firm a hold on the stock of the country, that there is not the least hope of being able to stamp it out by the application of any simple and drastic measures which have been effective in eliminating other infectious diseases.

Applying to our own country the lesson to be learnt from American experience, he considers that it is useless to attempt the formulation of any general plan for the complete eradication of the disease within a limited period. Ambitiously comprehensive schemes end in failure and the wastage of public money. The problem must be attacked piecemeal, and the first step to take is to secure the slaughter of cows with advanced or generalized tuberculosis or with tuberculosis of the udder. This raises the question, Ought compensation to be paid for cows coming under this description?

It is impossible to study American experience of compensation without forming a definite opinion on that point. When a herd contains animals broken down with tuberculosis, it practically always contains also other animals in a less advanced but progressive stage of the disease. The mere elimination of the former animals does not produce a clean herd; the other infected animals gradually develop the condition of those already slaughtered, and continue by their faecal and other discharges to pass on the infection to new arrivals. So the process goes on indefinitely, and the payment of compensation for broken-down beasts is a positive encouragement for its continuation. Public money expended for this purpose is worse than wasted; by rewarding the farmer who is unwilling or unable to adopt effective measures of control, it actually aids in the continued propagation of the disease, and so contributes to a further diminution of the food-producing value of the live stock in the community.

The next steps towards the eradication of tuberculosis are: (1) By means of the tuberculin test, applied to entire herds, to discover the total extent of infection; (2) to separate permanently the healthy from the reacting animals; and (3) to confirm the first diagnosis of freedom from tuberculosis by a repetition of the test some months

later. These measures are essential if freedom from the disease is to be secured. But tuberculin testing requires skill and costs money, and, as the average farmer cannot afford to pay for it out of his own pocket, the expenditure should come out of the public funds, with the exception of a small fee to be exacted from the farmer as evidence that he is earnestly desirous of obtaining the knowledge which will help him to eliminate tuberculosis from his cattle. The farmer will then have the opportunity of treating his cattle on the Bang system; and, in districts where there is substantial evidence that this system is appreciated, further assistance might be given to him. For example, in herds which become nearly, but not quite, free from tuberculosis, the community might take over the few remaining animals which react, on terms advantageous to the farmer; but this could only be done in districts where the value of the tuberculin test has become appreciated—that is, where farmers recognize that cows which have passed the test are worth more money in the open market than untested or reacting cows. Another important way of helping the farmer is to educate him by providing him with accurate information as to the financial loss which bovine tuberculosis involves, the economic advantages of getting a clean herd, and practical methods of obtaining one. And of all educative influences, it is urged, there is none better than the force of example.

The most effective way of teaching the farmer the way to success is to show him, in his own district, that success actually is being achieved. Local authorities, by establishing and maintaining clean herds for the supply of public institutions, would provide a valuable means of educating the farmer.

LOCAL MILK REGULATIONS.

The essential basis of authority in America resides in the right of the local board of health, by the exercise of its own unaided powers, to prohibit the sale of unwholesome milk. This right has been sustained in the law courts, and is supported by public opinion. But it must be understood that the American local authority does not usually enforce, or even attempt to enforce, every requirement which happens to be on its official code of rules and regulations. These codes are often drawn up on idealistic principles, setting forth what the health officer ought to endeavour to enforce; he accomplishes what he can, but his achievements usually fall short of the ideal. Aggressive regulations, demanding more than the producer can reasonably perform, do more harm than good; they are always evaded, cause much irritation, and satisfy nobody. But the medical officer usually learns by experience what rules he can enforce and what he had better allow to become a dead letter; and, using his powers with discretion, he is able to make appreciable progress.

Actual reforms are mainly due to the acceptance of reasonable recommendations offered by the medical officer, and are attributable to the recognition rather than to the exercise of this officer's right of direct intervention.

Theoretically, the medical officer has the right to withhold or revoke a "permit," that is, a licence to sell milk, for any and every breach of the municipal regulations; but in practice he exercises this right very sparingly, and only for very substantial cause, and therefore the system works well, and inflicts no hardship on the honest dealer. The advantage of the permit system is that it provides a more prompt and effective way for checking flagrant abuses than the clumsy method of prosecuting in the magistrate's court, and seeking the imposition of a fine. Closely connected with the permit system is the right of imposing conditions which must be fulfilled before milk can be permitted to enter a city. Here again, when the conditions imposed are reasonable, the exercise of this right is proving a very valuable aid in the endeavour to secure a wholesome milk supply. In short, the lesson which other countries might profitably learn from the measure of success which has been attained in America is that "it would be an advantage to entrust to the local health authorities reasonable and legally-defined powers of direct control over the production and sale of milk."

SPECIAL ASPECTS OF THE MILK PROBLEM.

The author's investigations into the production of pasteurized milk led him to the following conclusions:

Commercial pasteurization is firmly established, and cannot be abolished; but it seems both possible and desirable to institute a system of inspection which shall provide a guarantee

¹ Reports to the Local Government on Public Health and Medical Matters. New series, No. 1. London: Published by Wyman and Sons, 1907. To be obtained through any bookseller. 5d.

that the work is done efficiently, with regard to the interests of the consumer and in accordance with the standard of skill, care, and cleanliness already observed by the better class of firms. Whilst official encouragement or enforcement of pasteurization might be objectionable, it would appear useful and reasonable to insist that pasteurized milk shall be sold as such, in order to enable the consumer to choose for himself between the pasteurized and the raw article.

In many American cities the attempt has been made to establish a "bacterial standard" for milk—that is, a requirement that milk exposed for sale shall not contain more than a specified number of bacteria per cubic centimetre. Attempts to enforce compliance with these standards have generally failed, but nevertheless the interest which has been aroused in the bacterial contents of milk has served a useful purpose, and it is now recognized both by health inspectors and by many business firms that simple bacteriological tests are of practical utility as indications of the quality of a milk supply.

Routine bacteriological examination of samples for the guidance of the milk inspection service are valuable, and should be adopted. They afford the most reliable, the cheapest, and often the quickest means of discovering when milk has been improperly handled. Upon the pathogenic effects of many of the bacteria commonly present in milk further research is needed.

On the cooling of milk to a temperature not exceeding 50° or 55° F., much stress is laid in some American cities, particularly New York, but Dr. Eastwood does not consider that it would be possible to compel English milk sellers to comply with this requirement.

Attempts are being made in some American localities to grade milk according to its quality. These endeavours lead Dr. Eastwood to suggest that a useful purpose would be served in this country if some official restriction were placed on the fancy designations of milk at present in vogue, such as "pure," "nursery," "medically inspected," "from tuberculin-tested cows." He proposes that a regulation should be established requiring all milk to be sold under one of three designations—namely, "raw," "pasteurized," or "officially certified."

A brief description is given of the American "medical milk commissions," which aim at the production of thoroughly wholesome milk. The writer considers that these "commissions" are making slow but appreciable progress, and that they are worthy of imitation. In commenting on the limited degree of success which some of them have attained, he remarks that sufficient attention has not yet been paid to the employment of common methods of commercial enterprise in "pushing" this commodity. And, he adds, "municipal enterprise in the production of certified milk for the purpose of improving the physique, and therefore increasing the wage-earning capacity of the poorest classes, is also worth considering."

In many American localities the inspector fills up a report on each place he visits in the form of a "score card," assigning so many marks out of a given maximum for each detail on which it is his duty to report. Commenting on the practical working of this system, Dr. Eastwood says: "Given competent, honest, and tactful inspectors, the score card system works well, and is advantageous alike to the health authority, the producer, and the consumer. Its most important service is that it provides a steadily applied stimulus to voluntary improvement, where the conditions fall far short of the ideal but do not lend themselves to correction by coercive measures."

Discussing problems of milk transit and comparing American with English methods, he writes: "The fact that in the American trade milk is hauled in dust-proof receptacles demonstrates the absurdity of the notion that ventilation holes are necessary. On arrival at its destination by rail, milk should be in sealed cans bearing the name of the farm where it was produced. Promiscuous mixing of milk intended for sale without pasteurization is undesirable. If some mixing be necessary for the purpose of averaging the quality of milk sold as raw milk, the dealer should be saddled with the responsibility of labelling the mixture with the names of the two or more sources from which it was obtained. When milk is sold in bottles, official supervision is desirable to ensure the bacteriological cleanliness of the bottles and bottling apparatus."

BRITISH MEDICAL BENEVOLENT FUND.

At the April meeting of the Committee twenty-three cases were considered, and grants amounting to £204 5s. made to twenty of the applicants, two cases being passed over as unsuitable for help and one postponed for further inquiries. Appended is an abstract of the cases relieved:

1. M.R.C.S., I.L.R.C.P., aged 51. Has been incapacitated for some time by ill health and exhausted all his resources; is now better, and able to undertake a little light work, but requires immediate help to purchase a few necessary articles of clothing, etc. Voted £2 5s.
2. Widow, aged 38, of M.B., Ch.B. Glasg. Lost her husband soon after marriage, and is at present dependent on relations who can ill afford to help. Proposes to train as a maternity nurse, and friends promise to pay part of the expense. Voted £5 conditionally upon the balance of the money being found.
3. Widow, aged 60, of M.R.C.S. No income; endeavours to support herself by letting lodgings; children only able to give very slight help. Relieved three times, £34. Voted £18.
4. Widow, aged 61, of M.R.C.S. Quite unprovided for at recent death of husband, whose means were exhausted by a two years' illness. No children. Voted £12.
5. Daughter, aged 61, of late M.R.C.S. No means; has been given a home for some years past in return for services, but fears she will soon have to give it up. Voted £5.
6. Daughter, aged 64, of late M.R.C.S. No income; used to act as housekeeper to a brother, and after his death qualified as a maternity nurse, but now obtains so few cases that she is obliged to apply for help. Voted £12.
7. Widow, aged 56, of L.R.C.P., L.R.C.S. Edin. No income, and since husband's death twenty years ago has supported herself as children's nurse, etc., but has recently been incapacitated by a serious illness which has exhausted her small savings. Voted £12.
8. M.R.C.S., aged 70. Until a few months ago was in practice but had recently undergone an operation for gangrene, and is now quite incapacitated. Slight help from children. Voted £18.
9. Daughter, aged 59, of late M.R.C.S. Allowed 5s. a week by friends and earns about the same amount by needlework. Relieved twice, £30. Voted £12.
10. Daughter, aged 59, of late M.R.C.S. Is given a home in return for services, but requires help for dress and other unavoidable expenses. Health very indifferent. Relieved seven times, £108. Voted £12.
11. Daughter, aged 48, of late M.R.C.S. Is a confirmed epileptic and consequently unable to follow any occupation. Dependent on a brother-in-law, who can ill afford to help, and receives £10 a year from the National Hospital for the Paralysed and Epileptic. Relieved twice, £22. Voted £12.
12. Daughter, aged 43, of late M.R.C.S. For many years past has been obliged to nurse her recently deceased mother, an annuitant of this Fund. Hopes now to support herself by letting rooms, but requires a little help meanwhile. Relieved once, £5. Voted £5.
13. Daughter, aged 66, of late M.R.C.S. Has supported herself by teaching for forty-three years, but is now unable to do so. Health indifferent and sight failing; no means; earns a few shillings occasionally by knitting. Relieved once, £12. Voted £12.
14. Widow, aged 62, of L.F.P.S. Glasg. Only income £10 a year from a charity. No children. Lets rooms, but has great difficulty in obtaining lodgers, and is in a very bad health. Relieved six times, £60. Voted £10.
15. Daughter, aged 60, of late M.D. Aberd. Has given music lessons for nearly forty years, but finds increasing difficulty in getting pupils, and is in a very feeble state of health. Relieved twice, £20. Voted £10.
16. Widow, aged 49, of L.R.C.P., L.R.C.S. Edin. No income. Dependent on two sailor sons, both at present out of work. Relieved five times, £51. Voted £12.
17. Widow, aged 61, of M.R.C.S. Eng. No income. Slight help from friends; a son sends a few shillings occasionally. Is quite incapacitated by permanent ill health. Relieved three times, £36. Voted £12.
18. Daughter, aged 53, of late M.R.C.S. Is unable to earn a living, and dependent on three sisters who have to support themselves. Voted £5.
19. Daughter, aged 25, of late M.R.C.S. Health quite broke down after nursing her mother through a long illness, ending in death, and for some months past has been an inmate of different institutions. Relieved once, £5. Voted £6.
20. Widow, aged 66, of L.R.C.P. Lond. No income. Unprovided for at husband's death, about twenty years ago, and has supported herself by a boarding house, but now finds it impossible to make both ends meet. Relieved three times, £36. Voted £12.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 15, Wimpole Street, London, W.

LITERARY NOTES.

MESSRS. WITHERBY and Co. have in preparation a work entitled *A History of the Birds of Kent*, by Mr. Norman F. Ticehurst, M.A., M.B., F.R.C.S. Eng., who has for many years been well known among ornithologists as a close observer of the avifauna of the county. The work will be published by subscription, and only a limited edition will be issued.

In the *Periodical* for April we find some extracts from Wilson's *Art of Rhetorique* (1560), which has just been published by the Oxford University Press, with an introduction and notes by Mr. G. H. Maer. Two of these concern our profession, and may interest our readers. They are as follows:

When an vnlerned Phisitien (as England lacketh none such) had come to *Pausanias* a noble Gentleman, and asked him if he were not troubled much with sickness. No sir (quoth he) I am not troubled at all, I thanke GOD, because I vse not thy counsaile. Why doe yv accuse me (quoth the Phisitien) that neuer tried me? Marie (quoth *Pausanias*) if I had once tried thee, I should neuer haue accused thee, for then had I beene dead, and in my graue many daies agone.

An English Phisitien ryding by the way : and seeing a great companie of men gathered together, sent his man to know what the matter was, wherupon his man understanding that one there was appointed to suffer for killing a man: came riding backe in al post haste, and cried to his maister, long before he came at him: get you hence sir, get you hence for Gods loue. What meanest thou (quoth his maister). Mary (quoth the fernant), yonder man shall dye for killing of one man, and you I dare saie, haue killed a hundred men in your daies: get you hence therefore for Gods loue if you loue your self. . . .

It would be easy to give modern equivalents of these hoary-headed jests. The mind of man seems to be incapable of conceiving anything new in the way of jibes against doctors. They but change their dress with the time; the essence of the jest is ever the same.

To the *Caledonian Medical Journal* for April Colonel Kenneth Macleod contributes some interesting reminiscences of the Edinburgh Medical School as it was half a century ago. Speaking of John Goodsir, he says he has never been so impressed by the appearance of any man as by the person, mien, and manner of the famous professor of anatomy when he delivered his introductory lecture. Tall, spare, and bent, robed and clothed in black, with strong features, grave, thoughtful, earnest expression, eyes full of intelligence, which warmed and flamed as he proceeded, long arms, large shapely hands, slow gestures, and deliberate utterance, he presented the aspect of a scientific devotee. In his fourth year Colonel Macleod acted as prosector, and executed on a special subject a dissection of the pneumogastric and sympathetic nervous systems from end to end, with their distribution and intercommunications, which he believes is still preserved in the anatomical museum and used for demonstrations. While engaged on this work he was one day introduced to Goodsir by Professor Allen Thomson, of Glasgow, who was in search of a senior demonstrator. Colonel Macleod's youth and inexperience in teaching were against him, and Dr. John Cleland was chosen for the post. Colonel Macleod's anatomical work, however, stood in good stead when, many years afterwards, he was appointed Professor of Anatomy in the Calcutta Medical College. Robert Christison he describes as a strikingly handsome man, with a singularly strong, intellectual face. Colonel Macleod had the good fortune to serve under Syme as a dresser. He describes the great surgeon as follows:

A small, neat man, with a compact figure, shapely hands and feet, a plain but clever face, and a large head, he was dressed in a black dresscoat and tweed trousers, and wore a high collar with a large check stock. He drove in a big coach drawn by a pair of fine horses. He was a man of few words, but these were very much to the point. His voice was weak, feeble, and thick. When lecturing he sat on a chair in the well of the operating theatre, and had another placed beside him on which the patient, if able to walk, was seated. He generally saw him for the first time, and with a few pertinent questions and a rapid examination, he soon made his diagnosis, and explained the nature and treatment of the case in a few pithy sentences. When visiting the wards he made very few remarks. He was seen at his best when operating. He was collected, neat, quick, and resourceful. He knew what had to be done, and did it. He never changed his coat for an operation, but sometimes turned up his cuffs and sometimes his coat collar. His operations for traumatic aneurysm, by opening the sac and tying the artery above and below, were magnificent. He was a most kind, hospitable man, and devoted to botany and horticulture.

He concludes with a sketch of university life as it was in his day. The University Union was not in existence. The university was, in fact, a sort of big day school. There were, however, several literary, musical, and athletic societies and clubs which brought students pleasantly together. The Royal Medical and Hunterian Societies gave opportunities of mental improvement and agreeable association. The dissecting rooms and hospital were a common meeting ground, and good fellowship prevailed in all the classes, and mutual help and encouragement were cheerfully given wherever students assembled together. Medical students were a hard-working, well-behaved lot, and very few of them led an idle or fast life. Those best acquainted met in each others' rooms—generally of a Sunday evening—for a quiet chat over the "cup that cheers," and sometimes held a discussion or examination on the subjects of study.

To the *Bulletin of the Johns Hopkins Hospital* for January Dr. John E. Donley contributes an account of John James Wepfer, a physician of the period of the Renaissance, who specially studied apoplexy. Wepfer was born at Schaffhausen in 1620, and after studying at Basel and Strassburg, and afterwards spending two years in the universities of Italy, he returned to his native land and took his Doctor's degree at Basel in 1647. In the same year he was appointed physician to the city, and was granted the then unusual privilege of making *post-mortem* examinations. In 1675 he was appointed physician to the Duke of Württemberg, and shortly afterwards to Charles the Elector Palatine. He served with armies in the field at different times; when over 70 years of age he worked so hard in combating an epidemic fever which was ravaging the army of the Emperor Leopold that he died of the effects of overwork at the beginning of 1695. In accordance with his expressed wish an autopsy was made, and it was found that there was calcification of the aorta, a condition of which he had himself conjectured the existence. His chief work is a treatise on apoplexy (*Observationes Anatomicae ex Cadaveribus eorum quos sustulit apoplexia*) the first edition of which was published at Schaffhausen in 1658. It was reprinted at the same place in 1675 and at Amsterdam in 1681, 1710, and 1724. Wepfer gives the history of four cases of apoplexy with reports of the *post-mortem* examinations. He describes his method of opening the skull and removing the brain with its vessels. He gives a clear description of the vessels of the dura mater, of the vertebral and internal carotid arteries with their branches and their terminal ramifications coursing in the pia mater and entering the substance of the brain. He describes the arrangement of arteries at the base which is now known as the "circle of Willis." There is no allusion, however, to Wepfer's book in Willis's *Cerebri Anatome* which was published in 1664. Wepfer discusses the venous sinuses and expresses the opinion that the arteries of the dura mater as well as the internal carotids and vertebrals transmit their blood ultimately to the longitudinal sinuses whence it passes by way of the jugular veins back to the heart. His view as to apoplexy was that it occurred either because the afflux of blood was denied to the brain or because the efflux of animal spirits from the cerebrum and cerebellum was prevented, or, in certain cases, because both these causes acted together. Anything which prevents the influx of blood to the brain through the carotids or the vertebral arteries and its return through the jugular veins was, according to Wepfer, capable of producing apoplexy; and this influx to the brain might be hindered by obstruction of the internal carotid and vertebral arteries by compression of these arteries, or finally by blood extravasated within the brain. He observed that blood extravasated within the cranium would cause apoplexy if it was copious in amount and lay in the deeper parts, particularly about the base. Dr. Donley thinks that Wepfer probably gives the first systematic account of apoplexy in which the condition is explained in accordance with the new theory of the circulation of the blood. Wepfer was the author of researches on the effects of hemlock and other poisons and of several other works. He was a hard worker, seldom going to bed before 11 and rising at 4. He devoted the first part of the day to prayer and to the reading of the Scriptures, both in Greek and in Latin. He was never

idle throughout the day; even at meals he was busy with a book or with his correspondence. So great was his eagerness for knowledge that when the opportunity of investigating human bodies was lacking he studied the lower animals, his observations on which he frequently communicated to his professional brethren.

Medical News.

A SPECIAL meeting of the Dermatological Section of the Royal Society of Medicine will be held at 20, Hanover Square, on May 20th, at 5 p.m., when Dr. Louis Wickham, of the Radium Institute, Paris, will give a lecture-demonstration on the therapeutics of radium.

THE annual general meeting of the Medical Defence Union, Limited, will be held at the Medical Library, University College, Bristol, on Thursday, May 27th, at 4.30 p.m., when the annual report will be presented and the usual statutory business carried out.

WE are asked by Captain Montgomery Smith, the Honorary Secretary, to state that the annual meeting of the Volunteer Medical Association will be held at 20, Hanover Square, on Wednesday, May 5th, at 4 p.m., for general business and the election of officers.

A SPECIAL meeting of the Irish Medical Schools' and Graduates' Association will be held at Harrogate on Saturday, May 22nd. Arrangements have been made with the Majestic Hotel to allow of members remaining until Monday to visit places of interest in the neighbourhood. Full particulars may be obtained from the Honorary Secretary, 30, Myddelton Square, E.C.

THE summer post-graduate session at the Hospital for Sick Children, Great Ormond Street, W.C., will commence on Thursday next, May 6th, when Dr. Batten will give a demonstration on cases of cerebral tumour in children. On May 15th Mr. Corner will deal with selected surgical cases. The lectures are at 4 p.m. on each Thursday, and are free to all qualified medical practitioners.

DR. LEONARD HILL, F.R.S., Lecturer on Physiology in the London Hospital Medical School, is one of the wise hard workers who rides a hobby, and to such good purpose that a collection of his paintings in oil and water colour form an interesting little one-man show which will be open until May 11th at the Corner Gallery, so called because it is in the house at the corner of Old Bond Street and Piccadilly. Dr. Hill belongs to the impressionist school, and the most striking quality of his work is an appreciation of colour values well shown in what is probably the best piece in the collection, a black cock retiring vanquished from combat. There are several other brilliant animal paintings and a number of near landscapes, most of which show a love of sunlight, particularly a finished sketch of a woodland garden with daffodils. Altogether the show leaves the impression that Dr. Hill might have made another career for himself had he so chosen.

THE tenth meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act was held at the Privy Council Office on April 28th, Mr. Almeric W. FitzRoy, the Clerk of the Council, presiding. The following witnesses attended and gave evidence:—Miss K. Stephenson, Honorary Secretary of the Wiltshire County Nursing Association; Miss Lilian Trendell, certified midwife, lately Inspector of Midwives for the County Council, and County Superintendent of the County Nursing Association in Herefordshire; Mrs. Elizabeth Miles, certified midwife, Hertford; Miss Alice Gregory, certified midwife, Honorary Secretary and District Superintendent of the Home for Mothers and Babies and Training School for District Midwives, Woolwich, Vice-Chairman of the London County Council Midwives Act Committee; Mrs. Messenger, certified midwife, Matron of the St. Margaret's Nursing Home, 30, Surrey Square, S.E.

THE first report has recently been received of an undertaking of some interest—namely, an institution for the training of children who are not only blind but mentally too defective to be able to profit by the tuition afforded in ordinary schools for the blind. It was established by Miss Meiklejohn a few years ago on the suggestion of Dr. Campbell, of the Royal Normal College, Upper Norwood, and last year was reorganized so as to be recognizable by the Board of Education as a registered special school. Its object is to endeavour to improve the mental condition of the children sufficiently to enable them to pass on to ordinary schools for the blind, and, failing this, to teach them to become decent and possibly useful members of an ordinary household. Children of both sexes are admitted,

and the school is permitted to receive not only children sent by public education authorities but also private cases. There are vacancies now for blind and defective girls belonging to middle-class families, but the managers of the school are specially anxious to have placed in their charge quite young children, as they offer the best chance of success. Children from any part of the country can be received, as, though the title of the school is the Hastings and St. Leonards Special School for the Blind, the connexion is merely one of locality. As far as we are aware, this school stands by itself among such institutions, for, though the London County Council makes special provision for defective blind boys, there is no school which caters specially for blind and defective girls. By the regulations of the Board of Education its accounts have to be audited and published in a prescribed form, and the children must be instructed by a qualified teacher and housed in accordance with the regulations of the Board of Education, to whose inspection it is at all times open. These are points of interest, for it can never be made entirely self-supporting, and, in default of assistance from charitable sources, it may prove impossible to keep it open for long. It has its habitation at 48, Kenilworth Road, St. Leonards-on-Sea.

A QUARTERLY court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held on April 14th. Dr. Blandford, President, in the chair. Eleven directors were present. It was reported that since the last meeting three members of the court had died—Mr. T. Laurence Read, Vice-President, and Dr. Eastes and Dr. Chas. Baker, directors. Votes of condolence with the families of these gentlemen were passed. Two medical men were duly elected members of the society. One of the annuitants, an orphan, had died. Her mother, up to the time of her death, had also been in receipt of grants. The father had paid in subscriptions £14 14s., and his widow and orphan had received from the funds of the society £960. Five letters asking for relief had been received from widows of medical men, but had to be refused, as their husbands were not members of the society. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. The subscription is two guineas per annum, and relief is only granted to the widows and orphans of deceased members. Full particulars may be obtained from the Secretary at the offices of the society, 11, Chandos Street, Cavendish Square, W. The invested funds of the society now amount to over £100,000. Thursday, May 20th, was fixed for the annual general meeting, due notice of which will be posted to the members on May 1st.

THE second International Congress on Industrial Accidents will be held at Rome from May 23rd to 27th, under the patronage of the Italian Government. Its programme of work was indicated in the BRITISH MEDICAL JOURNAL of March 20th, p. 736. For the benefit of any readers who may wish to take part in the proceedings, it may be repeated here. The subjects to be dealt with are: (1) The organization of a medical and surgical service for the treatment and observation of the consequences of industrial accidents, and the principles which should guide doctors who have to give expert evidence on the subject. (2) The diagnosis and prognosis of neuroses caused by industrial accidents. (3) The estimation of working capacity before and after the accident; this includes: (a) Methods of examination for that purpose; (b) the importance of the state of health before the accident (predisposition, previous illnesses, etc.); (c) anthropological and sociological factors (race, age, sex, criminality, etc.); (d) the influence of phases in the legal procedure, inquiries by magistrates, medical examinations, etc.). (4) The influence of the mode of compensation on the development of post-traumatic nervous affections. (5) Statistical observations from the medical point of view as to the consequences of the application of the compensation law. (6) Functional adaptation of injured limbs. Communications relative to the congress should be addressed to the general secretary, Via Borgognona 38, Rome: the subscription (Fr.20) should be sent to the treasurer, Professor A. Ascarelli, at the same address. Reports introductory to discussions should not exceed sixteen and papers should not exceed eight printed pages in length. The honorary presidents of the executive committee are Professor Baccelli, Deputy to the Italian Parliament, and Professor Durante, Senator of the Kingdom. A committee formed for the purpose is arranging a programme of festivities and excursions. Ladies belonging to the families of congressists are admitted to membership at a subscription of Fr.10.

British Medical Journal.

SATURDAY, MAY 1st, 1909.

SPIRITUAL HEALING.

WHATEVER else may be said of him, Mr. W. T. Stead has a keen eye for the sensation of the hour. Therefore it was inevitable that he should give us his views on faith healing. Christian Scientists, he says (in the *Review of Reviews*, February and March), Psychotherapists, Magnetic Healers, and Spirit Healers have discussed with him how they do their mighty deeds. That they do them, he adds, no one can doubt; and has not Dr. Schofield assured us that faith-healing is a reality? Impressed by this convincing testimony Mr. Stead has looked into the matter, and passes various types of "healer" in review.

First we have the late Father John of Cronstadt who, if his devotees are to be believed, has a long list of miracles to his credit. That he had the indefinable gift of exerting spiritual influence seems to be unquestionable, and no one who knows how such influence can act upon the body in certain conditions will be disposed to deny that he may have wrought cures of nervous disorders in some cases. But he was under no delusion as to the limitation of his healing power, and he was so far from taking up the attitude of most "healers" that he declared that "those 'commit murder who will not have a doctor to attend 'them, or another person who is ill and requires the 'doctor's help.'" He attributed whatever he did in the way of healing to prayer, a belief in which as a curative agent has been held and acted upon by the Church from the time of its institution. Father John was in fact a saint of the type of those who flourished in the "ages of faith," when whatever ill could not be traced to the action of evil spirits was regarded as a punishment or trial inflicted by God.

Next in Mr. Stead's collection of "healers" comes Mr. F. L. Rawson, of London, a consulting electrical engineer, who finds the key to the mystery of disease and its cure in electricity. Even prayer, if we understand him, is a form of electrical action. He believes that Mrs. Eddy has discovered the method by which Christ wrought His miracles and that Christian Scientists heal sin and sickness in the same way. But he explains her metaphysics in terms of natural science. The ether, he says, consists of lines of force at right angles to each other. At some of the places where these lines of force or high-tension electrical currents cross, the electrical tension rolls them up into a sort of knot. This is the electron, now recognized as the smallest particle of matter, and matter is simply a massing together of these electrons, or, in Christian Science language, it is a manifestation of thought; the lines of force being simply the natural science name for thoughts. By the action of the human mind, by strong, determined thinking or will-power, this electrical tension can be released and the matter then disappears, but the thoughts that caused

the trouble are still there, and roll up again in some other form of trouble. When a person prays in the right way the action of God causes these lines of force and the electrons as well to be short-circuited, as in the cases of instantaneous healing of cancer and tumour. Mrs. Eddy, says Mr. Rawson, describes the whole action and interaction of the ether in metaphysical terms; for instance, she speaks of error destroying itself, which means the short-circuiting action of the two ends of adjacent particles on each other, one end being positive and the other end negative. She calls these thought germs. The true natural science explanation of the action of thought and matter is merely Mrs. Eddy's metaphysical explanation expressed in terms used in natural science, and for the first time in the world's history we get religion, science, and metaphysics absolutely agreeing; only they have not yet discovered that this is so owing to their using different terms, and to one side being too busy and the other not loving enough. This lucid explanation should be sufficient to convince any one that Mr. Rawson can do wonders with words. Of the marvels of healing which he claims to have performed, Mr. Stead can scarcely trust himself to speak. He confesses, indeed, that he has not had the opportunity of collecting and sifting the evidence of those who have benefited by Mr. Rawson's treatment; this, we may hint, would be somewhat hard to do, as his power is said to extend to raising fallen cab-horses in the street by the power of "right thinking." Nevertheless Mr. Stead, who would seem to be as much above evidence as the Emperor Sigismund was above grammar, "can vouch for the fact" that he has done great good and achieved results in "cases which have baffled the efforts of the faculty" and all friends who have been sought to relieve "sufferers both by the mediation of the medical 'pharmacopoeia and by the conventional method of 'prayer.'" What does Mr. Stead consider the voucher of one who has had no opportunity of sifting the evidence to be worth? Mr. Rawson, we are told, is not without hope that he may be able to banish death from the world. In this, if we are to believe a witness quoted by Mr. Stead, his electricity is less potent than the metaphysics of the Christian Scientists, some of whom are said to have raised people from the dead. It is true Mr. Stead is inclined to believe that they were not really dead; but if there be no such thing as death, what difficulty can there be in conjuring away a mere delusion? We have, by the way, to thank Mr. Stead for a delightful phrase; he says the testimonies given at meetings of Christian Scientists "are 'enough to stagger the most credulous!'" No wonder they staggered him.

We have next brought before us a Mr. W. H. Edwards, a magnetic healer, who claims that he effects all his cures by the direct help of his spirit friends. With an apparent simplicity in which may, perhaps, lurk a grain of malice, Mr. Stead tells us that he introduced Mr. Edwards to Mr. Rawson, "but the two 'healers did not benefit each other.'" Perhaps, like the soothsayers of old Rome, they had to use up all their electric and magnetic force in suppressing a tendency to laughter.

Of Mr. J. M. Hickson, the President of the Society of Emmanuel, we hear that he casts out devils, heals the sick, and does everything short of raising the dead. From a list of "typical cases" Mr. Stead selects the following remarkable "cure." The patient "fell and 'injured the patella, which had previously been 'broken four times. Two doctors expressed the

"opinion that he would never have full use of knee again. It was very painful and quite callous (*sic*) at the time of first treatment by prayer, but in twenty minutes he was able to bend it without help, the following day to walk about the house, and after four visits to resume ordinary duties." This beats bone-setting.

Here a question may suggest itself to the profane mind. As we have so many persons among us endowed with such supernatural gifts, how is it that their beneficent activity makes no appreciable impression on the amount of sickness and death which the Registrar-General still has to record? Mr. Stead does not know what to think of the marvels he has heard, and ends with the sage reflection that "so long as mortal men are really healed, so long will they go to the healers, let the doctors say what they will." To which we are tempted to reply: "Let them go; if there is anything really the matter with them they will come back again." As an illustration we may mention a sad case within our own knowledge. A man with some slight symptoms of bladder trouble consulted an eminent specialist, who discovered a small growth which could easily have been removed. It was arranged that the patient should undergo the operation. In the meantime, however, he fell among Christian Scientists, who persuaded him that he was quite well. And, indeed, for a time the symptoms almost ceased. But the insidious disease remorselessly went on its way, till the unfortunate patient was past all surgery. We repeat that what is wanted is a complete and well-authenticated account of these spiritual, electric, and magnetic cures, with the fullest details of the cases and their ultimate results. We make bold to say that these would be "enough to stagger the most credulous."

NEPHROPEXY AS A PANACEA.

THE foible of popular and even of professional medicine is to run after panaceas; antimony, mercury, venesection, tar-water, have each played their parts; and in later times hydropathy, electricity, massage, radiant heat, and systems of diet have made bold bids for the same universal validity. The means used must be new and capable of creating a distinct impression, while they must not be demonstrably injurious, or at least their use must not be attended by a high rate of mortality, or they are scarcely likely to attain great popularity. Only in recent times have surgical proceedings been capable of entering as competitors for this position, unless we include trephining, which in a distant past appears to have been looked upon as a remedy for many diseases of very various etiology. But antiseptic or aseptic surgery has rendered it possible to recommend as remedies for all sorts of symptoms operations which would previously have been dangerous in themselves. The pioneers were the gynaecologists, and the cervix uteri was at first the favourite object of their operations; this part of the human body a few years ago was indifferently either split asunder or stitched up in order to cure identical maladies which were with more or less confidence declared to depend upon the presence of certain local conditions these procedures were designed to remove. With the improvement in surgical technique gynaecologists became bolder, and transferred their attention to the uterine appendages, which were removed to cure epilepsy, hysteria, and

even insanity, with sufficient success to give plausibility to the remedy for a time. Space will not allow us to detail every operation which could be quoted from the history of the last few years, but among the latest is nephropexy, which finds a strong advocate in Mr. Billington, of Birmingham. His experience extends to 150 cases upon which he has operated for movable kidney during the past three years, and he divides them into five groups—a convenient classification, as probably no one denies that there are cases of the kind for which the operation is not only justifiable but necessary. The cases constituting his first group, are those in which the prominent symptom is local pain made worse by the upright position and by exertion, and relieved by lying down. Unfortunately, Mr. Billington does not state the number of these cases on which he has operated, but we may infer it by subtracting those given under the other headings. He enumerates 112 in the second, third, and fourth groups, but gives no details about the fifth, so if we assume that about 30 cases were in his first group we shall not be far wrong, and if all were similar to the three examples given the treatment calls for no criticism. The second group was made up of those patients with symptoms associated with the digestive system, such as would be called nervous dyspepsia. Of the two cases given as examples, in neither can it be said that a cure was effected, and although Mr. Billington says he "has every reason to be satisfied with the results in the twenty cases" in which he has operated" the evidence he lays before us is inconclusive. In the third group the patients were suffering from symptoms of neurasthenia; and there, again, the examples given do not show complete cure, and Mr. Billington admits that "there have been failures." In Group 4 there were 12 cases of "undoubted lunacy," of whom 6 are claimed as cured; brief notes are given of 3 only, and of these 2 were instances of conditions of acute insanity from which spontaneous recovery might be expected; while of the third we should have liked more definite evidence of recovery than the hearsay statement quoted. Of the fifth group, which included cases in which the prominent complaint had reference to the female pelvic organs, Mr. Billington admits that his experience is limited, and he gives no details. He claims as the result of his experience to have proved that nephropexy is a safe and satisfactory surgical procedure, and while saying very properly that renal mobility alone is not an indication for the operation, he regards local pain of sufficient severity to diminish working efficiency as such an indication. This conclusion may be accepted, and it may be agreed that so far Mr. Billington has made out his case, but when he asks us to agree that chronic functional disturbances of the digestive system and progressive spinal and cerebral neurasthenia and insanity depend upon movable kidney and may be cured by stitching it in position, we remain in doubt.

Dr. Suckling has published a second edition of his book on *Movable Kidney*,¹ which contains an exposition of the principles upon which Mr. Billington's operative indications are based, and to which he refers. Dr. Suckling claims that the operation is a cure for insanity, neurasthenia, nervous dyspepsia, and many other conditions; and although there is no reason to doubt that in a certain number of cases improve-

¹ *Movable Kidney*. By C. W. Suckling, M.D. Simpkin, Marshall, and Co., Limited. 1909.

ment has followed, it is less easy to believe in the dependence of these nervous conditions upon the displaced kidney; the favourable results directly attributed to the operation may very well have been due to suggestion.

Sir W. Watson Cheyne has recently published* an address on movable kidney in which, while recommending a special method of performing nephropexy, he expresses his opinions upon some of the general questions we have been discussing. He is satisfied that the operation is a good one, and thinks that failures are due either to the fact that the loose kidney was not the main cause of the trouble of which the patient complained, to the organ not having been fixed in the proper position, or to its having again become loosened. In the causation of movable kidney he attaches most importance to congenital defect and to mechanical influences, but he doubts the importance of emaciation, as he says that in the *post-mortem* examination of patients with movable right kidney it has been found that the fatty capsule on the other side is "quite satisfactorily developed, and often remains in considerable amount even though the patient be emaciated." Hence he regards the treatment by keeping such patients in bed and trying to increase their fat as futile. He recognizes the direct effect of the mobility upon the kidney itself, which may become the seat of hydronephrosis or chronic atrophic nephritis, and also the production of such general symptoms as giddiness, anaemia, neurasthenia, and even insanity, quoting Dr. Suckling for this last statement.

With regard to the association of movable kidney with neurasthenia, Sir W. Watson Cheyne expresses the opinion that general enteroptosis is often present, and that when this is so the operation of nephropexy can only partially remedy the mischief, and is, therefore, contraindicated. General experience teaches that not only may no benefit result, but the state of the patient may be rendered worse, and he says that he has come across a good many cases in which this has occurred. He adds, however, that it is possible that the unfavourable opinion now entertained of the result of the operation in neurasthenia may have to be modified should Dr. Suckling's results be confirmed.

We do not understand why there should be any failures such as Mr. Billington admits, if the connexion between the displaced kidney and the nervous system is as close as Dr. Suckling believes. Mr. Billington says that he is now of opinion that where both kidneys are movable both should be stitched up, and that the double operation does not appreciably increase the risk. We recognize the logical nature of this conclusion; but if so, how does he explain the recovery of such a bad case as the second example of neurasthenia given under Group 3? In this patient both kidneys were down yet only one was fixed, but nevertheless at "the end of six weeks she climbed to "the top of the Herefordshire Beacon." Surely this case ought to be accepted as a splendid illustration of the excellent result of stitching up one kidney and of the harmlessness of the mobility of the other, and the only reason for rejecting this conclusion must be that it is totally opposed to Dr. Suckling's doctrine that renal mobility, even when slight and painless, is a cause of grave nervous disturbance, a doctrine which we believe to be not only unsound but dangerous.

VOX RECLAMANTIS.

THE most pushful politicians have what Sydney Smith called "flashes of silence"; controversialists sometimes cease from troubling, and even the popular preacher and the suffragette are occasionally quiet. But the voice of the quack is always heard in the land. This, of course, is the law of his existence, and we should be glad to pass him by with a *populus vult decipi*, were it not that he, his claims, and his testimonials are constantly thrust upon our attention by correspondents. If all the communications we receive on this subject were dealt with separately, there would be little room in the JOURNAL for anything else. We can mention only a few of them here. One correspondent has obligingly sent us a *Pocket Guide to Count Mattei's Medicines*. We fondly believed that this particular system of humbug had been exploded long ago. The pamphlet bears the name of A. J. L. Gliddon, who would seem to be the vendor of the remedies. It is interesting to recall that Mr. Gliddon was announced as the seller of a drink cure, the virtues of which were described in Mr. Stead's most flamboyant style in a letter which that inspired journalist contributed to the *Daily Chronicle* of October 30th, 1893. We note that Mr. Stead is quoted in Mr. Gliddon's pamphlet as saying that, if ever he had an attack of indigestion, he could always get rid of it in half an hour by using the Mattei remedies. Mr. Stead's eyes should have been opened to the real value of the Mattei remedies by his own experience as a member of a committee formed to test their use in the treatment of cancer. According to a report on the subject which appeared in the JOURNAL of August 13th, 1892, p. 369, Mr. Stead, who went into the investigation as a convinced Matteist, "expressed himself as thoroughly ashamed of his 'champions.'" But in the province of medicine Mr. Stead has what may be called an *anima naturaliter circulatoria*; by the temper of his mind he inclines to quackery. So far from being ashamed of this, he has, if we are correctly informed, been heard to boast of this mental peculiarity. In any case he would seem, in the matter of the Mattei remedies, to be even worse than the Bourbons in the matter of government: for whereas they learnt nothing and forgot nothing, he learnt something which he has since forgotten.

Another correspondent has sent us an advertisement announcing the discovery of a "breathing cure" for catarrh, adenoids, and nose breathing difficulties. The evil effects of breathing through the mouth are vividly described; we learn that the "pent-up catarrhal slime" finds its way into the liver and kidneys, causing all sorts of trouble. The cure has the simplicity of Columbus's famous egg demonstration; all that is required is that the nose should be freed by lifting the outer edges of the nostrils. As the learned doctor who communicates the discovery to the world raelly puts it, this "unstops the most stopped-up nose." But of course the matter is not quite so simple as this: "upon this first-step discovery has been built an 'anatomical-physiological cure, the details of which, 'are given fully in a book which can be obtained,' etc. In view of the far-reaching consequences which may be caused by neglected adenoids, it is a pity that persons who prey in this way on the credulity of the public, and the newspapers which aid and abet them in so doing, cannot be brought within the grasp of the law.

A third advertisement which has been brought

* *Lancet*, April 24th, p. 1155.

under our notice is chiefly remarkable for its extraordinary English. The advertiser, an Italian, complains bitterly of the "disloyal concurrence which is being made" to his product "by dishonest speculators 'although without the least initiative.' This, he says, 'constrains me, in the interest of Doctors as well as 'of consumers, to put them on the guard from the 'innumerable falsifications, imitations, and counterfeiting executed to a great extent by small as well as 'important vendors by illicit and dishonest means. 'Reserving the right to summon before the Criminal 'Court these audacious counterfactors, and awaiting serenely the results of the suits against those whom 'I have already denounced to the proper authorities, 'I beg to request Doctors to make use in their prescriptions of the phrase'—[here follows the name of his product]—'and the consumers to observe with 'diligence and care the existence of the specific indications of my firm, to which is due the merit of 'having enriched the Pharmacopoeia with a new potent 'drug approved and recommended by the Principal 'Italian and Foreign Scientists.' He goes on to say that "these Crystals, prepared with the greatest 'scientific care, represent the ideal cure in all the 'forms of arthritis, in Dispepsia, Intestinal Torpor, 'Uric and Biliary Litiasis, Urimia, Poliscarcia, and 'all other sickly forms dependent from the deviations 'of the material rechange." This catalogue of strange diseases almost persuades us to give the name of the remedy which cures them. On second thoughts, however, we refrain, lest the physician, who is slowly but surely being despoiled of his kingdom by ever-encroaching surgery, specialism, vaccine-therapy, and immunization, should find himself *roi en exil*. But while "urimiam" and "other sickly 'forms dependent from the deviations of the 'material rechange" remain, his occupation will not be entirely gone.

HOMES OF REST FOR DOCTORS.

It was announced not long ago that Mr. George Smith, M.R.C.S., L.D.S., of Newent, Gloucester, who died on December 19th, 1908, at the age of 77, and left estate valued at £11,669, had bequeathed the residue after the payment of sundry legacies to the Royal Infirmary, Manchester, and University College Hospital, London, in equal shares. The bequest is to be used for the benefit of one or more members of the surgical or dental staff of these institutions who may be disabled by infection from puncture, or who may have contracted blood poisoning whilst examining or operating on patients or after making *post-mortem* examinations. There is scarcely any other calling more exposed to physical danger of one kind or another than that of medicine. It is not uncommon to read of the death of a surgeon from septic infection contracted in the course of an operation, but comparatively few of these cases are ever heard of beyond the immediate circle of his friends. The amount of temporary disablement from this cause is very great. The public believes that the doctor bears a charmed life. This, as we know too well, is a mere superstition. From the threshold of medical study the student is constantly exposed to risk in the dissecting-room, in the deadhouse, in the hospital ward, in the operating theatre, in the sick-room; even in the laboratory invisible enemies encompass him around. If he escapes death, he is often disabled—it may be, permanently. Some of these risks dog his footsteps throughout professional life. Of exposure to weather,

of the ill effects of irregularity in meals, and of the anxieties inseparable from his profession which help to place the doctor almost at the bottom of the scale of longevity, we need not speak. Mr. George Smith's bequest will do something to relieve those who are incapacitated by a particular cause. But there remain innumerable other risks which bring about premature breakdown in medical practitioners, and the cases are too numerous in which disablement or infirmity overtakes them before they have been able to make any provision for their old age. There are, of course, the benevolent societies, in praise of which it would be impossible to speak too highly. But they are few, and their resources are insufficient to meet the demands made upon them. We therefore call attention to a scheme which has recently been set on foot in France with the approval and patronage of such men as Professor Landouzy, Dean of the Paris Faculty of Medicine; Professors Chantemesse, Fournier, Hutinel, Guyon, Lannelongue, Le Dentu, Lucas-Championnière; Dr. Roux, Director of the Pasteur Institute; Dr. Vaillard, Director of the Val-de-Grace; M. Mesureur, head of the Assistance Publique; M. Lépine, Prefect of Police; Professor Hugouennec, Dean, and Dr. Testut, professor, in the Medical Faculty of Lyons; Professors Mairot and Grasset, of Montpellier; and most of the directors and principal professors of the medical schools in France. The proposal is to create one or more houses of retreat, rest, and health for French doctors. The idea originated with Dr. Courtault, Editor of *Tablettes Médicales*, and Dr. Lucien Nass. In 1857 Orfila, the famous toxicologist, then Dean of the Paris Faculty, suggested a similar scheme, but death prevented his carrying it out. Dr. Courtault gives a distressing account of the present condition of the profession in France. The State, the department, the commune vie with each other in exacting more and more work at a lower wage from the doctor. To-day the provincial practitioner eats, sleeps, writes, and studies in his carriage. He early becomes rheumatic, and before long becomes unfit to compete with younger men. In the Department of the Seine, of a total of 3,500 doctors, 700 are in the receipt of assistance from various associations. When he is old, solitary, and disabled, the doctor is often compelled to migrate to some lonely spot that his poverty may not be known to his acquaintances. Of this we could cite various instances within our own knowledge in this country. We need only refer to the case of a famous teacher and hospital surgeon, long dead, whose name is in every textbook of physiology and surgery; yet he was rescued from actual starvation by the charity of his colleagues, to whom his condition became known by a fortunate accident. Nor is this by any means a solitary case. It is for such as these that the "Maison du Médecin," which it is proposed to found, is intended. It will belong to the whole medical body, and will be open to all—to those who can pay nothing as well as to those who can contribute a certain amount. It will be the aim of the directors to make the existence of the inmates as comfortable as in the best kind of boarding house. The charge will be £48 a year. In the case of those who have not sufficient means this sum will be paid by the Association or by the house itself; the council alone will know the terms on which the inmates are received. It will not be a poorhouse, but a refuge for honourable poverty, and above all a place of temporary rest for those who have been wounded in the struggle for existence. The first house will probably be situated on the borders of the forest of Saint-Germain. We should be glad to see something of the same kind established here.

ANTIVIVISECTION IN DUBLIN.

THE Irish Branch of the National Antivivisection Society held its annual meeting in Dublin on April 22nd. The report of the committee stated that the number of subscribers was 300. Mr. R. R. Cherry, K.C., Attorney-General for Ireland, who presided, after referring to the "horrors" of vivisection, said, with a humour which we hope was unconscious, that he did not wish to exaggerate. He went on to state that he knew that vivisectionists told them their experiments were carried out in so humane a manner by means of anaesthetics that really there was no degree of suffering on the part of the animals. He was good enough to add that, "if that was true," it was in a great measure true by reason of the action taken by that and similar societies in other parts of the United Kingdom. Of this statement Mr. Cherry vouchsafed no shadow of proof; and as it is part of the antivivisectionist case that animals are not in fact anaesthetized, it would be interesting to know on what ground Mr. Cherry made such a claim on behalf of these societies. If we may use a popular phrase, they cannot have it both ways. The Attorney-General for Ireland, who does not wish to exaggerate, proceeded to rehearse anew the old, old legend about the appalling increase of experiments, and how they were almost all done without anaesthetics. Really Mr. Cherry should leave this kind of thing to Mr. Stephen Coleridge, whose chief weapon in debate is to "ingeminate" the word "torture." Mr. Cherry says that under the existing Act a great amount of suffering is caused, "partly through callousness and partly through inattention to that Act." Clearly the learned gentleman had not got up his brief, and we should recommend him, before speaking on the subject again, to study the evidence given before the Royal Commission on Vivisection. We commend to his special attention the evidence of the antivivisectionist witnesses. A resolution was proposed by the Rev. J. Warschauer, in seconding which Dr. W. J. Cameron, according to a report which appears in the *Irish Times* of April 23rd, made the remarkable statement that in his student days he was in favour of vivisection, and performed many vivisections "after making sure that the animals were dead." This is, we suppose, how he learnt the art, in which antivivisectionist controversialists are so proficient, of flogging a dead horse. We have often had occasion to point out that the vivisection campaign is really a movement of perverted sentiment rather than humanity. Its essentially inhumane character is well shown by certain statements made by Sir John William Moore at the annual meeting of the governors of the Meath Hospital held in Dublin on April 10th. After acknowledging their indebtedness to the Distribution Committee of the Hospital Sunday Fund he went on to say that the subscriptions had fallen off within the last few years. He wished to state publicly that the charge which had been brought against that and other hospitals that vivisection was practised within the precincts of the hospital was a deliberate and unfounded falsehood. There was no such thing in connexion with any Dublin hospital, and it was a calumny to advance that statement. The statement had done harm to the Dublin Hospital Sunday Fund, as he had very good reason to know. Mr. Coleridge, writing in the *Irish Times* of April 23rd, professes to think that "it will afford sincere pleasure to all our readers to peruse these forcible repudiations of vivisection in connexion with hospitals," and he proceeds to improve the occasion by contrasting Dublin with London, as if vivisection were carried on in London hospitals. He has had every opportunity of learning that this is absolutely untrue. He

may, perhaps, remember that we ourselves helped to enlighten his mind on this point when he tried to make people believe that "clinical material" for the instruction of students meant living human bodies for the study of diseases by physiologists! If hospitals are not adequately supported, human beings must suffer. But what is that to the sentimentalists who shudder at the supposed "torture" of a guinea-pig which has undergone the prick of a needle?

THE RAT FLEA AND PLAGUE.

THE Commission for the Investigation of Plague in India, abstracts of the publications of which in the *Journal of Hygiene* have appeared in this JOURNAL from time to time,¹ adduced a mass of evidence in support of the conclusions (1) that in India human plague is conditioned by the epizootic among the rats, and (2) that the agent in transference from rat to rat and from rat to man is the common rat flea of tropical climates, *Pulex cheopis*. In the experiments carried out in Bombay the only means by which the Commission were able to produce epizootics amongst animals was by means of rat fleas. When precautions were taken to eliminate fleas from the houses in which the animals lived no epizootics occurred, notwithstanding the closest contact of infected animals with healthy ones. The massive infection of the floors of the houses with virulent cultures of plague bacilli was equally unsuccessful. The epidemiological observations of the Commission, both in Bombay and in certain Punjab villages, brought to light no facts in the least discordant with the animal experiments. All the epidemiological data collected could be adequately interpreted by the hypothesis that infected fleas transmitted the disease from rat to rat, and that when their natural host became diminished by the severe mortality of the epizootic, the insects sought man for a supply of nourishment, and so conveyed the infection in a percentage of cases. At the Bombay Medical Congress the discussion on plague in Section II was opened by a paper by Professor Kitasato, the Director of the Institute for the Investigation of Infectious Diseases in Tokio, and one of the discoverers of the plague bacillus. This paper was listened to with great interest, as only a few years ago Kitasato had stated his opinion that the rat flea played no part in the epidemiology of plague. The paper which was read by Professor Shiga, the Head of the Serum Department of the Tokio Institute and the Delegate of the Japanese Government to the Congress, gave a summary of some recent investigations made by Kitasato during a plague epidemic in a small town in Japan. The main facts elicited were as follows. In Japan as a general rule the common rat flea is not *Pulex cheopis*, but in the town in which the present epidemic took place *Pulex cheopis* amounted to 80 or 90 per cent. of the fleas taken on rats. The epidemic was accompanied by a severe mortality amongst the rats, and Kitasato brings forward evidence of the same nature as that accumulated by the Indian Plague Commission to show that the transmitting agent between the rat and man was the rat flea (*Pulex cheopis*). Guinea-pigs as traps were placed in plague houses, control animals being put into non-plague houses at the same time. The number of fleas caught in the former many times exceeded the number trapped in the non-infected houses. Again, a certain percentage of the fleas caught in the infected houses were found to contain abundant plague bacilli in their stomachs while none of those from the non-plague houses were shown to be infected. Further, animals in the laboratory were infected with fleas

¹ See 1906, vol. ii, p. 1045; 1907, vol. ii, p. 155; 1908, vol. i, p. 211, and vol. ii, p. 91.

from the infected houses, but none with those from the clean houses; and, finally, certain of the guinea-pigs let loose in the plague houses contracted the disease, while those placed in the control houses always remained healthy. In concluding the paper Kitasato stated that he had brought forward no new facts and that he had only confirmed the observations of the Indian Plague Commission, to the work of which he paid a high tribute of praise.

THE DEVELOPMENT OF TRYPANOSOMES IN TSETSE FLIES.

The Sleeping Sickness Bulletin for March, 1909, amongst other interesting papers, contains a notice of one by Professor Kleine from German East Africa, entitled, "Positive Infection with *Trypanosoma brucei* by *Glossina palpalis*." Dr. Bagshawe, the editor of the *Bulletin*, summarizes the conclusions obtained, and, if these ultimately turn out to be accurate, then a very important phase in the life-history of the trypanosomes will have been discovered. Professor Kleine fed tsetse flies (*Glossina palpalis*) for three days on sheep naturally infected with the parasite of nagana (*Trypanosoma brucei*), and after this from the fourth day onwards daily on fresh healthy animals. Up to the sixteenth or seventeenth day nothing seemed to happen, the blood of the experimental animals, though frequently examined, remaining free from parasites, but from the eighteenth to the thirty-ninth day and onwards trypanosomes appeared. The details of these experiments are as follows:—From the eighteenth day to the twenty-fourth the flies fed on the same sheep (No. 30) from the twenty-fifth day to the thirty-ninth on the same ox (No. 2); twelve days after the flies were put on No. 2 ox its blood showed trypanosomes, and so No. 30 sheep was then also examined and found to have parasites. All the previous animals remained healthy. From the fortieth to the fiftieth day the flies were fed on two goats, two calves, and two sheep; all became infected, the goats after eight and six days, the calves after six and five days, the sheep after seven and five days. These experiments seem to prove that flies which for many days after the ingestion of blood containing trypanosomes were not infective afterwards became so, and infected animals; and the most probable explanation is that the parasites underwent development in the fly analogous to that observed in mosquitos with the parasites of malaria and yellow fever. Dr. Bagshawe criticizes the experiment in some of its details, wild flies appearing to have been used instead of bred ones, and he asks the question, Were all the animals so placed that biting flies could reach neither the sick nor the healthy? The matter is so important that further independent experiments to confirm or confute Kleine's results are much to be desired, and we have no doubt they will soon be forthcoming, and will also clear up dubious points such as those mentioned above. The idea of a development of trypanosomes in tsetse flies is, of course, not a new one, most workers on the subject believing it probable: but until the present paper definite proof has not been forthcoming. The importance to sleeping sickness of the observation is that the life-history of the two trypanosomes, *gambiense* and *brucei*, is in all probability similar, and this will of course influence the prophylaxis of the human disease considerably.

ST. BARTHOLOMEW'S HOSPITAL.

In a detailed consideration of the future of London hospitals published in this JOURNAL on June 20th last year, note was made of the fact that the vast majority of all London hospitals were annually spending more

on ordinary upkeep than they were receiving in income, and were thus helping to pile up between them a vast burden of debt over and beyond that directly resulting from building operations. It was shown, too, that the oldest hospital in the metropolis, St. Bartholomew's, at one time a happy exception to the general rule, had at length put in an appearance among the debt accumulators. At that time the excess of its expenditure over its income was comparatively small, but reasons were given for anticipating that this balance on the wrong side would before long become as great in the case of St. Bartholomew's as in that of any of its fellows. This prophecy seems likely to be fulfilled with even greater speed than was anticipated, for a report by the new treasurer of the hospital, Lord Sandwith, shows that the excess of annual expenditure over annual income reached last year a sum of £8,000. In the case of many institutions the excess of annual expenditure on maintenance and administration over ordinary income is due to extravagance; not, perhaps, in the year in question, but at some recent period when schemes of enlargement have been adopted without sufficient funds to maintain the new beds, when provided, being either in hand or in sight. Many institutions, indeed, have multiplied their accommodation even though totally unable to maintain out of annual income the beds which they already possessed. The difficulties of such institutions are the natural result of forgetting the wisdom of cutting a coat according to the cloth provided. St. Bartholomew's, however, is not a case in point. It has never suffered from megalomania, and the number of its beds remains exactly what it was many generations, if not hundreds of years, ago. Its ambition, in short, has been, not to increase the amount of its work, but merely to perfect the fashion of its performance. Nevertheless, its balance on the wrong side is readily comprehensible. The expenditure of all hospitals not less than that of most householders is subject to what may be called a "natural" increase. This increase in the general cost of life, if scarcely perceptible at any given moment, is yet steady, and must in the course of time make a most material difference to any large institution. Hospitals, for instance, in spite of the work they do for the public, and especially for the poor, pay rates just like other people. Rates, as most of us know, tend constantly to increase, and many hospitals in London under this heading alone pay out upwards of £1,000 a year. This "natural" increase is comparatively unimportant at most institutions, since its effect is eliminated by the elasticity of income resulting from the multiplicity of the sources from which it is derived. In addition to receipts from invested property they annually receive large sums in the way of donations, subscriptions, and bequests, whereas St. Bartholomew's has hitherto practically depended on income from invested capital alone, and the net value of such incomes at the present day everywhere tends to decrease. The commencing difficulties of St. Bartholomew's are, therefore, perfectly comprehensible apart from any additional expenditure which may be thrown upon it by the improved fashion in which its work is conducted. The idea of St. Bartholomew's as an applicant for public support is somewhat of a novelty, for in a history of five or six centuries it made its first venture in this direction only some six or seven years ago, when, in accordance with the findings of an independent commission, it was decided to rebuild the institution and on its existing site. Unfortunately, the appeal then made threatened to coincide with a corresponding effort on the part of a very popular and

constant applicant for public support, and the most conspicuous net result was a crusade against St. Bartholomew's in the general press. Happily this onslaught failed in its professed object, but it had the effect of leaving an impression on the public mind that St. Bartholomew's was a very rich institution which stood in no need of donations, subscriptions, or legacies. Whatever may have been the case at that time, the position is now changed, and the institution, a magnificent example of hospital enterprise, should receive the same meed of support from the public as that accorded to kindred institutions, which are its rivals, it is true, but only in good works and scientific efficiency.

THE SLEEP CURE.

In these days of strenuous life, sleep shows more and more a disposition to follow Astraea and go back to heaven, from which, according to Elizabeth Barrett Browning, it came:

Of all the thoughts of God that are
Borne inwards into souls afar,
Along the Psalmist's music deep,
Now tell me if that any is
For gift or grace surpassing this—
"He giveth His beloved sleep!"

How many of those whose fate it is to spend themselves in the stress of a struggle for a livelihood would echo those words! The difficulty is that the gift comes not to all. Large towns with their various noises, —or what is in some cases worse, the intervals of suspense when the wakeful sufferer, like Carlyle, waits for the next crow of the importunate cock—murder sleep as effectually as Macbeth. Hence the large use of hypnotics at the present day, and the ceaseless search of investigators to find one that shall lap the weary brain in the Elysium of a refreshing sleep without leaving headache or dullness or other ill effect behind. High-frequency currents, massage by a skilled hand, and hypnotism, are not within the means of all, even if they could be depended upon to produce the desired result. We have often wondered why in these days of various therapeutic enterprise the idea which inspired Thomson's *Castle of Indolence* has not been applied for the treatment of the victims of sleeplessness. There all things tending to foster sleep were combined with subtle art:

A pleasing land of drowsyhed it was:
Of dreams that wave before the half-shut eye;
And of gay castles in the clouds that pass,
Forever flushing round a summer sky:
There eke the soft delights, that witchingly
Instil a wanton sweetness through the breast,
And the calm pleasures always hovered nigh;
But whate'er smacked of 'noyance, or unrest,
Was far far off expelled from this delicious nest.

The inmates there did not sit "and hear each other groan"; there were "no dogs, no babes, no wives to stun the ear"; "no curséd knocker plied by villain's hand"; but the soft music of the Æolian harp, and the soothing sound of falling waters brought sleep to tired lids. Even the howling of the wind was made into a lullaby:

And oft began
(So worked the wizard) wintry storms to swell,
As heaven and earth they would together melt:
At doors and windows, threatening, seemed to call
The demons of the tempest, growing fere;
Yet the least entrance found they none at all;
When sweeter grew our sleep, secure in massy hall.

We now learn from the *Gazette Médicale du Centre* that what may be called a castle of sleep has been established by Dr. Lemesle, of Loches, in Touraine—that province of so many joyous memories and associations, where the climate is mild and equable, and the air, as Duncan says, "nimble and sweetly recomends itself unto our gentle senses." Dr. Lemesle

uses physical agents, such as fixation of the eyes on a bright object, and the monotonous ticking of a clock, to lull the senses of his patients. If these means, with the surroundings in which the patient is placed, do not succeed, he uses blue light. It was observed by Lumière of Lyons that people employed in workshops illuminated by red light became nervous and were quickly tired; these effects ceased when blue light was substituted. Dr. Lemesle, therefore, keeps his patients in a blue atmosphere; the glass in the windows is blue, and all the decoration and furniture of the room is of the same hue. At night the electric light shines through blue globes. Absolute silence is enjoined throughout the establishment. Dr. Lemesle, in fact, has carried into effect, with modern improvements, the conditions of a restful life imagined by the author of the *Castle of Indolence*. His aim is to make his patients spend as much time as possible in sleep, waking up at intervals to take food. The sleep cure, we have no doubt, would be most useful to many—for a time. The pity of it is that it is beyond the reach of those who need it most.

M. LUCAS-CHAMPIONNIÈRE.

THE annual address to the Cardiff Medical Society will, as has already briefly been announced, be given this year by M. Lucas-Championnière. The subject of the address, which will be delivered at 3.30 p.m. on Friday, June 4th, is the Modern Treatment of Fractures. The annual dinner of the Society—to which it will be glad to welcome any member of the profession who desires to be present—will be held on the evening of the same day, and afterwards M. Lucas-Championnière will formally make the presentation of the Lynn Thomas and Skyrme Fund. To this fund, as our readers are aware, subscriptions have been received from medical men in all parts of the world, and it is therefore very appropriate that this presentation should be made by M. Lucas-Championnière, since he is President of the International Surgical Association. M. Just Lucas-Championnière was born in 1843 at St. Leonard, Haute Vienne, the birthplace also of Gay-Lussac, the physicist. The future surgeon began his medical studies in Paris in 1860, graduated M.D. in 1870, and became surgeon to the Paris hospitals four years later. In the interval he paid a visit to Great Britain at the time when Lister was organizing that revolution in surgery the full significance of which it was not given to every one of that day to perceive. The young French surgeon, however, saw clearly that facts were being established which would entirely change the whole attitude of mind of the surgeon, and when he returned to his own country he at once applied Listerian principles in his own work. In the face of criticism, opposition, and some little ridicule he practised and advocated antiseptic surgery, not only by example but also by precept, for the first edition of his work on the subject was published in 1876. As an original thinker his name is more especially associated with the immediate treatment of fractures by massage and mobilization, the subject which he has selected for his address at Cardiff. M. Lucas-Championnière has retired from active surgical practice, but he is honorary surgeon to the Hôtel-Dieu and a member of the Academy of Medicine, while his cosmopolitan reputation is proved by his election at Brussels last year to be the President of the International Society of Surgery, an office in which he has been preceded by Professor Kocher of Berne and Professor Czerny of Heidelberg. M. Lucas-Championnière was present as a guest at the Annual

¹ Tickets, price 7s. 6d., and all further particulars can be obtained from the Honorary Secretaries of the Society, Dr. F. P. S. Crosswell, 24, Windsor Place, or Dr. William Martin, 17, Windsor Place, Cardiff.

Meeting of the British Medical Association in Sheffield last year, and received the honorary degree of D.Sc. from the University. We feel sure that he will find as warm a welcome and will make as many friends in the Principality this year as in Yorkshire in 1908.

COAL MINE BATH-HOUSES.

It is no uncommon sight in a pit village in the Northumberland and Durham coalfields, and possibly in others, to see a coal miner, freshly returned from the pit, being scrubbed down in a hot bath by his wife, for in fine weather, at any rate, it is or was customary to go through these very necessary ablutions *coram publico*. They were very thorough with, so we are informed, the curious exception that they did not include the back; the collier, it seems, entertains the belief that if the back is washed it is weakened. How this superstition arose we do not know, but one consequence is that that part of the northern miner's person escapes soap and water unless he happens to be off work for a considerable time. The whole system seems a little primitive, but Mrs. Grundy, being accustomed to it, was not shocked. Recently, however, there have been some questionings, and proposals for establishing bath-houses at the pit heads, but, so far as we know, they have not materialized, and it has been left for the Fife miners to take the lead in this matter. The experiment, it is understood, is about to be tried in connexion with one of the Fife Coal Company's mines. The idea is to provide bathing accommodation for the miners, so that on leaving the pit after the completion of their shift they may be indistinguishable from other members of the community except, perhaps, for the added purity of their skin. The details are still under consideration, but it is stated that the accommodation will be provided on such a plan that it can readily be extended to meet any fresh demands. The baths will be of the spray description.

SUBTOTAL HYSTERECTOMY AND THE MENSTRUAL FUNCTION.

HOWARD KELLY¹ deprecates radical operation on the uterus as a routine measure. He not only practises myomectomy in preference to hysterectomy for fibroid, but also leaves portions of the body of the uterus in operations for fibroid tumours, where myomectomy would be unsafe, and for haemorrhagic uteri. He refers to the good results claimed by Zweifel, Spinelli, and Doran, where a portion of endometrium is saved, as well as one or both ovaries. Doran four years ago² reported the after-history of sixty cases in which he had performed subtotal hysterectomy, and showed that the physiological results were satisfactory. Kelly follows their practice, keeping a portion of the uterine body, with its mucosa, above the cervix in women who are still menstruating. It is sufficient, he insists, to retain a little pocket of the mucosa within the uterus big enough to lodge the end of the little finger, though more should be kept if possible; with the mucosa the corresponding portion of the muscular investiture is included. This end is obtained simply by carrying the knife through the uterine wall well above the cervix; the tissues thus preserved are sutured face to face, so as not to interfere seriously with the blood supply. It is absolutely necessary that in any case one or both ovaries be sound enough to be retained. Kelly practises two varieties of this conservative amputation. The first is horizontal resection, the operation performed by Doran; it is, Howard Kelly considers, the best in

cases of fibroid uterus. The second is vertical resection, a wedge being taken out of the centre of the uterine body beginning at the fundus and reaching down to the cervix, so that half or more of the uterine body with its mucosa is removed. The two raw surfaces are then approximated and closed with catgut sutures. Vertical resection is, he thinks, preferable in cases of subinvolved haemorrhagic uteri. A kind of utriculus is left after horizontal or vertical resection, which continues to menstruate moderately, and obviates the evils of an acute menopause. In conclusion, Kelly reports nine typical cases in which this conservative operation has been followed by the best physiological results, independently of recovery from the operation.

INTERNATIONAL CANCER RESEARCH UNION.

The Central Committee of the International Cancer Research Union held a meeting at Berlin, under the presidency of His Excellency Professor Czerny, on April 16th. The foreign committees were represented as follows: The Belgian, by Professor Willems of Ghent; the Danish, by Professor Fibiger of Copenhagen; the French, by Dr. Borel of Paris; the Japanese, by Surgeon-General Kawaschima; the Swedish, by Professor John Berg of Stockholm. Among the German members present were Professors Bumm, Kirchner, and Orth of Berlin. A report of the progress of the Union in various countries was presented. The question of establishing stations for the examination of preparations of cancer with the object of facilitating the early diagnosis of the disease was discussed. Another scheme which was considered was the foundation of museums for the promotion of cancer research. The commission for the investigation of cancer appointed not long ago by the King of the Belgians was affiliated with the International Union. On the invitation of the French Cancer Research Society, it was decided to hold the next meeting of the International Conference in Paris towards the end of September, 1910. At that Conference a report based on statistics collected from various countries and on the results of operation for cancer will be presented.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Education (Administrative Provisions) Bill gave rise to a very interesting debate on April 23rd. Mr. Dunn, in moving the second reading, said the bill proposed to amend the Act of 1907 dealing with the medical inspection of children, and the provision of meals provided for by the Act of 1906. By the first clause of the present measure the local education authority would be relieved of the final responsibility of saying whether a child was underfed or not, and the duty would be imposed on the school doctor, medical officer of health, or other medical official. Children supposed to be underfed would be examined by the medical inspector, and if they were reported as needing nourishment, it would be the duty of the local authority to feed them. If the halfpenny rate were not sufficient to cover the cost, the rate could be increased. In some districts the local authorities had refused to avail themselves of their powers under the Act of 1906. Mr. W. T. Wilson, a Labour member, seconded the motion for the second reading. He argued from the grave conditions that existed in some districts that it was the bounden duty of the State to undertake the work of feeding the children and concluded that the cost to the rates would be more than counterbalanced by the efficiency of the children. Sir Francis Powell moved the rejection of the bill, and, reviewing the work done under the existing Acts, argued that, considering the magnitude of the question, it was premature to reopen it. They ought to obtain more

¹ Amer. Journ. Obstet., April, 1909, p. 570.

² Trans. Obst. Soc. Lond., vol. xlvii, 1905.

experience, before opening the field of work, in many districts most satisfactorily done, to the boundless increase of the burdens of the ratepayers. Lord Morpeth seconded the motion for rejection, and argued against the powers proposed to be given to the medical profession. It would be dangerous, he said, to give the medical profession full power to order the feeding of children without the final check of the common sense of laymen. Sir William Collins, while sharing the sympathies of the supporters of the bill, was anxious that these important questions should be decided by the dictates of their heads rather than by the impulses of their hearts. He was inclined to think that the duties proposed by the bill would not add to the dignity of the members of the medical profession, and certainly not to that of the local authorities. While recognizing the obligation on the parent and on the State with regard to the children during their school life, he was not prepared to go beyond the great experiment in the Acts of 1906 and 1907. A great deal of valuable information was being collected under the existing law, and most difficult questions were arising on the results of medical inspection, as to medical treatment, and how it was to be afforded. The questions of feeding, inspection, and treatment all hung together, and he thought it would be unwise, without further serious investigation, to amend the recent legislation. The second reading was supported by Mr. Parker, Mr. Curran, Sir J. Duckworth, and in a very passionate and pathetic appeal by Mr. Crooks. On the other hand, Sir F. Banbury, Mr. Peel, Mr. Scott, Mr. H. Gooch, and Mr. Harold Cox opposed, and the last-mentioned speaker, in attacking the measure as an attempt to transfer the children from the care of their parents to that of the State, raised a sharp outburst of opposition from the Labour members, which was voiced by Mr. Ramsay MacDonald and Mr. A. Henderson. Mr. Runciman, as Minister of Education, opposed the second reading, and described the bill as a measure of public charity. It had not been proved that the Act of 1906 had failed; 193 local authorities said they had not found it necessary to put it into force, either because there was no local need, or because the children were otherwise provided for. Some eighty authorities had availed themselves of the statute. The bill would set up different, and possibly conflicting, jurisdictions, and did not limit the provision of food to children incapable of deriving advantage from education. In this respect the bill went far beyond the Act of 1906, and was really a Poor Law proposal, and would, if passed, embarrass the Government when, next session, they had to consider Poor Law administration. The bill was thrown out by 206 votes against 82.

The Local Education Authorities (Medical Treatment) Bill, which passed the second reading stage late at night last week, has been referred to Standing Committee A.

The Exclusion of Unvaccinated Children from Schools.—Sir Maurice Levy last week asked the President of the Board of Education a question as to the exclusion of unvaccinated children from endowed schools, schools assisted out of the rates, or schools entirely self-supporting, and Mr. Runciman replied that he was advised that governors of endowed schools regulated by schemes made under the Endowed Schools Acts and Charitable Trusts Acts were not as a rule prohibited by the scheme from excluding an unvaccinated child if they considered that so to do would promote the welfare of their trust. But in the case of schools, whether endowed or not, which received grants from the Board under their secondary school regulations, the Board would not regard the absence of vaccination as a reasonable ground for the exclusion of a day pupil, though they would be unwilling to interfere with the discretion of the governors in the case of boarders.

Local Government (Scotland) Bill.—Mr. Cathcart Wason asked the Lord Advocate if he was aware that practically all the Scottish members supported the proposal to put Scottish Poor Law medical officers in the same position as regards right of appeal as their brethren in England and Ireland; and if the Government would afford facilities for the second reading to the Local Government (Scotland) Bill in order that the case might be duly considered in

Committee. Mr. Ure replied that he was aware that the bill referred to received considerable support. Parish councils, however, were by no means unanimous in the matter, and without evidence of more general concurrence on their part the Government were not prepared to adopt the course proposed. Mr. Cathcart Wason then asked if the right hon. gentleman was aware that the Secretary for Scotland, in reply to a deputation a year and a half ago, promised that this matter should receive consideration when the Local Government (Scotland) Bill was before the House. Mr. Ure said he had given it consideration and found that the local authorities were not by any means in universal agreement on the subject.

Certification of Deaths (Scotland).—Mr. Weir called the attention of the Lord Advocate on Monday to the fact that during the years 1903-7 there were 2,915 uncertified deaths in Ross-shire and Inverness-shire and asked what action the Government intended to take to remedy this state of things. The Lord Advocate replied that no action can be taken without legislation, which was not at present in contemplation by the Government.

Consumptives from Canada.—Mr. Weir asked the President of the Board of Trade, having regard to the fact that under Canadian law emigrants from this country who developed consumption within two years after arrival in Canada were required to return, was he in a position to state what precautions had been taken by steamship companies, in vessels sailing from Canadian ports to the United Kingdom, to isolate consumptive passengers in such a way as to prevent other passengers running the risk of infection. Mr. Churchill replied that the steamship companies informed him that persons returning from Canada on account of consumption were carefully isolated during the voyage, and kept apart from the other passengers.

The Sale of Disinfectants.—Mr. Rees asked the President of the Local Government Board whether, in view of the promise made by him in June, 1907, and the statement of Professor Hewlett in the recent Milroy lectures, delivered before the Royal College of Physicians, to the effect that during the years 1905, 1906, and 1907, 28,000 gallons, 37,000 gallons, and 66,000 gallons of liquid were sold as disinfectant under the Privy Council Order of July 31st 1900, whereby grocers and oil and colourmen were prohibited from selling disinfectants containing more than 3 per cent. of carbolic acid, the result of which, as the leading authorities all agreed, was to place a premium on adulteration and inefficiency, he would now state what steps he contemplated taking to remedy this evil. Mr. Masterman, replying for the President, said, as he had stated in reply to a previous question, the Local Government Board was not empowered to fix standards of disinfectants, and it did not appear to him that he could usefully take action in the matter. He might add that there was little public advantage in the domestic use of disinfectants as deodorants. Where they were used to remove infection they were commonly employed under the advice of a medical officer of health or other medical man, who could be trusted to order disinfectants which were efficient.

The Metropolitan Ambulances Bill, to enable the London County Council to establish and maintain an ambulance service in London, was presented on Tuesday by Sir William Collins and supported by Colonel Lockwood, Sir Walter Foster, Sir William Bull, Mr. Dickinson, Mr. Corrie Grant, Mr. Steadman, Mr. Straus, Mr. T. W. Wilson, and Mr. Waterlow. The second reading was fixed for May 10th.

The Dogs (Exemption) Bill.—Last week Mr. Ellis Griffith presented a bill to exempt dogs from painful experiments. It is supported by Colonel Sandys, Sir F. Channing, Mr. Field, Mr. Weir, Mr. Tomkinson, Mr. MacNeill, Mr. Clement Edwards, Mr. Crooks, and Mr. Sloan. It was put down for second reading on Wednesday.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

THE PROVIDENT AND CHARITY ORGANIZATION SOCIETY.

In the annual report of this society just published a list of its aims is given, and it appears that besides the administration of several charities which are in its hands, including an old age pension fund and the Convalescent Home at Southport, the principal aim of the society is to encourage co-operation between individuals and charitable agencies so as to prevent misapplication of relief and the evils of overlapping. It invites the co-operation of all who are interested in any kind of charitable aid, and has a staff of officers whose business it is to inquire into the previous history of individuals and families, the means by which they maintain themselves, their liabilities, whether they have made any attempt to provide for times of want, and how far friends or relatives have assisted or are willing to assist them. Associated with it is the Manchester and Salford Provident Dispensary Association. Among other agencies which employ the society to make inquiries on their behalf are the Manchester Royal Infirmary, the Salford Royal Hospital, the Northern Hospital, and Ancoats Hospital, St. Mary's Hospital, the Victoria Dental Hospital, and the Manchester Midwives Supervising Committee. The total number of cases investigated by the society during the last year was 64,351, of which the first four hospitals mentioned above furnished no less than 52,595. In making its returns a general wage limit is taken, and persons in receipt of more than this are reported as not fit cases for free hospital treatment. The scale is 14s. a week for single men or women, 21s. for married couples without children, and 1s. 6d. extra for each child. This scale is adopted for all the hospitals on the list, and, as far as applicable, by the Midwives Supervising Committee. The report gives some interesting details of the cases investigated for the Royal Infirmary, the Salford Royal Hospital, the Northern Hospital, and Ancoats Hospital, in-patients and out-patients being taken separately, as shown in the following table:

Analysis of Cases Investigated for the Four Hospitals.

Belonged to other towns ...	In-patients ...	82
	Out-patients ...	6,540
Could not be found ...	In-patients ...	86
	Out-patients ...	2,131
Deserving free treatment ...	In-patients ...	1,697
	Out-patients ...	39,461
Able to join provident dispensary ...	Out-patients ...	2,275
	Out-patient ...	6
Able to pay a doctor ...	Out-patient ...	6
Able to make some payment	In-patients ...	317

Total number of cases received from the four hospitals ... 52,595

The most striking thing in these figures is that out of 50,413 out-patients, only 6 are returned as "able to pay a doctor," while 2,275 are returned as able to join a provident dispensary. The 6 cases able to pay a doctor are found all to come from the Salford Royal Hospital, which sent 9,808 cases for investigation. Of the remaining 40,605 out-patients, coming from the Manchester Infirmary and the Northern and Ancoats hospitals, not a single case is returned as able to pay a doctor. No one acquainted with these hospitals will accept this for one moment as properly representing the true state of affairs. It is evident that an extremely high wage standard must be taken in judging of ability to pay a doctor, and probably the majority of the 2,275 cases returned as able to join a provident dispensary ought to be regarded as able to pay a doctor. This figure would represent 5.46 per cent. of the total out-patients, but even this is no criterion of the amount of hospital abuse that goes on, as the following considerations will show.

Taking the out-patients only, which number 50,413, we find that no less than 6,540 came from other towns, and were not investigated at all. Presumably it would cost each of these a fair amount for travelling to and from the

hospitals, and in a large proportion of cases the cost of travelling would have been sufficient to pay a local doctor. Again, no less than 2,131 gave a wrong address, or at any rate could not be found. Here again, probably, a large percentage were afraid of investigation. Further, as a rule, cases are only sent for investigation after their first attendance, and probably only those likely to require a long attendance are given to the investigators. That something of this sort must take place is seen by comparing the total number of out-patients at the hospitals with the number sent in for investigation. In 1907 the out-patients at the Royal Infirmary numbered over 43,000; last year it was about the same. But of these less than 25,000 were given to the provident society for inquiry. It is difficult to believe that all the remaining 18,000 were beyond doubt suitable for free treatment without inquiry. Further, when the society has supplied to the hospitals with the results of its inquiries, its duties are finished. But it is quite certain that in very many cases the hospitals take absolutely no notice of the statements of the investigators. There may be some reason for this, for when a patient is found not to be suited for free treatment the investigators mark the hospital card with the letters "P.D." which unfortunately may stand for either "Private Doctor" or "Provident Dispensary." Most people, including the hospital authorities, take these letters to mean that the patient is able to join a provident dispensary, but no provident dispensary will accept a person who is ill at the time without an extra subscription which may be prohibitive at the time, and so little notice is taken of cards so marked and free treatment is continued as before.

Taking all these facts into account it is evident that the figures given by the society are no criterion of the amount of hospital abuse that takes place in Manchester and Salford. This may not be the fault of the society; its figures may be correct as far as they go. But if all the out-patients attending at the hospitals on any one occasion are taken into account, it would probably be more nearly correct to treble or even to quadruple the percentage, 5.46, which is supposed to represent the number of those not suited for free treatment.

Turning to the in-patients, 15.75 per cent. are reported as able to make some payment. Only 2,182 cases were given to the society for inquiry, and of these 168 were not followed up, as they either came from other towns or could not be found, while 317 were found to be able to make a payment. But it by no means follows that they are asked to do so, though some of the hospitals try to get something from them. Here again only a small proportion of the total in-patients were investigated. For instance, the Manchester Infirmary has about 5,000 in-patients a year, but only 945 were investigated, of whom 40 could not be found, and 165 were reported as able to make some payment. Thus the figure 15.75 per cent. is no criterion of the actual truth, though here again the society is not to blame. It may be noted that no in-patients were investigated for the Northern or Ancoats hospitals, though possibly some had been investigated as out-patients before being admitted as in-patients.

Of the cases sent to the society by the Midwives Supervising Committee no particulars are given, but from the annual report of the medical officer of health for the previous year, it is seen that out of 288 applications for payment by medical men for attending midwives' cases, 26 patients were found to have an income above the scale. The authorities refused to pay for these, leaving the doctors who did the work to get their fees as best they could.

Taking all things into consideration it is evident that the society is doing good work, but it is sorely hampered by the failure on the part of the hospitals to take full advantage of the facilities which it offers for preventing hospital abuse, and there is more than a suspicion that even the investigations which are made are not always utilized as they ought to be.

LIVERPOOL.

THE SLEEPING SICKNESS EXPEDITION.

At a recent meeting of the African Trade Section of the Liverpool Chamber of Commerce, Dr. Allan Kinghorn, a member of the sleeping sickness expedition of the

Liverpool School of Tropical Medicine, gave an address upon the investigation of sleeping sickness. He said that tsetse flies had a very wide distribution over the whole of the territory with which the expedition had been dealing, and cattle diseases, due to various varieties of trypanosomes, and referable finally to the agency of these flies, were abundant everywhere. The absolute safety to life ensured by European administration, the opening of markets for the sale of local produce, and the demand for a constant and abundant supply of labour had resulted in an unprecedented movement amongst the native population: and as until very recently no checks had been imposed on this, many new foci of sleeping sickness had been established, and the price was now being paid. Most Governments were taking action, but the harm was done before the cause and method of spread of the disease were known. It was formerly thought that only the negro race was affected. The comparative safety of the white man was due to his clothes and the other conditions under which he lived. Wherever the *Glossina palpalis* existed in the presence of an infected person there existed the danger of the spread of human trypanosomiasis. Whilst this species of fly, known as the river fly, was capable of transmitting the disease, some doubt existed as to whether it was that fly only which could do so. He considered it safer to hold the view that other species of tsetse fly might transmit it. In order to check the spread of the disease the indiscriminate movement of the native population must be controlled. Should any district be found to be infected the natives should not be allowed to travel beyond its borders until it had been shown that they were not suffering from this disease. The *Glossina palpalis* required shade, and could be got rid of by making clearances along water courses; the clearing, however, must be thorough. To deal with sleeping sickness was a matter of international importance, and could only be accomplished by international co-operation.

WEST YORKSHIRE.

BRADFORD ANTHRAX INVESTIGATION BOARD.

At a meeting of this board on April 19th, Dr. Enrich, Bacteriologist to the Board, reported that since the last meeting in February two cases of anthrax had occurred. During that period he had examined 111 samples contributed by thirteen firms, a great majority of which were blood-stained, but in only one sample—of blood-stained Cape mohair—had he found anthrax spores.

THE NOTIFICATION OF BIRTHS ACT.

At the annual meeting of the Liversedge District Council, held last week, it was determined to adopt the Notification of Births Act, 1907, complaints having been made that the infantile birth-rate in the district was excessive. The rate for the township is 135.8 per 1,000, compared with 121 for England and Wales. Some strong protests were made against the adoption of the Act, but they were of no avail, as the majority of members were in its favour.

NEWCASTLE-UPON-TYNE.

BARRASFORD CONSUMPTION SANATORIUM.

The annual report for the year 1908 shows that 113 patients have been treated at the Newcastle and Northumberland Sanatorium at Barrasford during the year. The sanatorium was opened in May, 1907, so that it is at present too early to judge of the continuance of the good results which are evident when the patients leave the institution. Even better results could, in the opinion of the medical staff, be obtained if the patients were able to make a longer stay in the sanatorium, but the charge of two guineas a week which the committee is obliged to make may have something to do with this. A limited number of patients can obtain admission to the Newcastle Corporation beds, and the workmen of Sir W. G. Armstrong, Whitworth, and Co. support five beds. The medical report shows that the institution is doing good work. From May, 1907, when the sanatorium was opened, until September, 1908, 90 patients—52 males and 38

females—were discharged, and the following table shows the general result in these cases:

Males.	Females.
22 are at work.	12 continue to improve.
2 ready to start work.	13 are in statu quo.
6 are in statu quo.	5 are not doing well.
6 are not doing well.	5 have not been heard from.
8 have not been heard from.	3 have died.
8 have died.	

During the year 1908 89 patients were admitted and 70 discharged; of these, the pulmonary condition was considered to be arrested in 12, much improvement in 29; in 20 there was some improvement, and in 10 none.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

WOMEN'S NATIONAL HEALTH ASSOCIATION.

HER EXCELLENCY THE COUNTESS OF ABERDEEN opened a tuberculosis exhibition in the Rotunda, Dublin, on behalf of the Women's National Health Association, last week. In the course of an address, Lady Aberdeen said the exhibition had visited about 100 places in Ireland, and last week it was opened in the Black Pitts District and Dolphin's Barn. She thanked the various medical men who had come to give demonstrations. In the evening Dr. Hope, Medical Officer of Health for Liverpool, gave a lecture at the Royal Dublin Society on "Public Health Work in Liverpool in Special Relation to Tuberculosis and Infantile Mortality." The chair was occupied by His Excellency the Lord Lieutenant. Dr. Hope said that in many respects the two cities had, independently of each other, been working on somewhat similar lines. The death-rate from phthisis in Liverpool had fallen from 1.9 in 1895 to 1.4 in 1907. In proof that improved dwellings produced good results, he stated that the mortality in former insanitary areas showed that the rate in a period of three years was 1.35 lower than the rate for the city taken as a whole—that is to say, was about half the rate which formerly existed amongst the same class of people in their old surroundings. No practical sanitarian would suggest that if, instead of demolishing insanitary dwellings, the money had been spent in private hospitals and sanatoriums for consumptives, the results would have been at all comparable. He then entered into detail as to the various methods followed in Liverpool in the treatment of tuberculosis, and the beneficial results which had been realized, and referred to the methods adopted in Liverpool for the diminution of infant mortality. He expressed his admiration of the methods followed in the Dublin Milk Dépot. In Liverpool the milk dépot cost the City about £2,000 a year, but the corporation did not grudge the money provided it could be shown that good was resulting, and that infant life was being saved. On the motion of Sir John Byers, seconded by Dr. Cox, a vote of thanks was passed to Dr. Hope.

The report presented to the second annual meeting of the association stated that there were now 172 branches. Thirty nurses had been appointed to as many branches which had collected funds for that purpose. Several branches had raised funds in order to obtain sanatorium treatment for patients. Cookery lessons formed part of the winter work, and demonstrations were given as to how cheap meals could be provided for consumptive patients. Prizes had been offered for well kept cottages. A pasteurized milk dépot had been established by the central association as an object lesson to demonstrate the saving of infant life which could be effected by providing pasteurized milk. The tuberculosis van, provided through the generosity of the Trustees of the Pembroke Charities Fund, had visited 103 places, where lectures were given to crowds of people. At the International Congress of 1908 held in Washington the first prize for effective work had been divided between this Association and the New York Association for the Prevention of Tuberculosis. The income for the year was £2,819 11s. 5d., and the expenditure £2,896 13s. 6d.

On the same evening Dr. R. W. Philip (Edinburgh) gave an address on the part to be played by the consumption

dispensary in the tuberculosis campaign. He said it was an error to suppose that the British Isles were pre-eminent as a tuberculosis centre. As a matter of fact, England and Scotland occupied the lowest place in the table of mortality from tuberculosis in the world, and Ireland, he had no doubt, would soon take its place beside the sister countries. Tuberculosis was much more common amongst school children below the age of 15 years than was generally supposed, and in support of this statement he mentioned, amongst other things, that out of 16,589 consecutive cases attending the dispensary in Edinburgh, he found that no fewer than 1,917 cases occurred in children below 15 years of age—that was to say, 11.5 of the whole. Much time and energy had been wasted on ill-considered and partial measures for the eradication of the disease. The factors in a well-organized and co-ordinated scheme were—first, a tuberculosis dispensary; secondly, notification; thirdly, a hospital for advanced and dying patients; fourthly, a sanatorium for the cure of early cases; and fifthly, a work colony for the further treatment of selected patients to whom a return to work meant a relapse. He was happy to say that in Edinburgh each one of these factors was at present in operation. He then dealt in detail with the work of the consumption dispensary, which was of first importance, and which, if properly worked, should be the centre of antituberculosis operations. The significance and strength of the dispensary lay in its close relationship to the other factors in the scheme. He was satisfied that the key of success in the campaign was to be found in the co-ordination of effort along those different lines.

Dr. Stafford, in proposing a vote of thanks to the lecturer, said that the county councils would have power after July 1st next, under the Tuberculosis (Ireland) Act, to establish consumption dispensaries, and carry out the whole programme indicated by Dr. Philip.

Sir John W. Moore, M.D., Chairman of the Dublin Hospitals Tuberculosis Committee, seconded the resolution, which was supported by Professor McWeeney.

Sir Charles Cameron occupied the second chair, and a vote of thanks to His Excellency the Lord Lieutenant for presiding was passed, on the motion of Mr. Lentaigne, President of the Royal College of Surgeons, seconded by Dr. Hearn, Armagh.

PUBLIC HEALTH IN BELFAST.

The Belfast Health Authorities and the Local Government Board of Ireland do not seem to be able to agree. Some few weeks ago public money was being spent in taking counsel's advice as to the liability of the City Council for part of the expenses of the late Belfast Health Commission; the lawyers of the City Council gave an opinion which differed from that held by the Local Government Board. At the meeting of the Public Health Committee on April 22nd a letter was read from the Local Government Board refusing to sanction the proposed increase of the salary of the medical officer of health of Belfast from £600 to £800 by four annual increments of £50, and saying that in 1906 the Board urged the Corporation to offer a salary which would attract candidates with high qualifications and extensive practical experience in the sanitary administration of a large city; that after full deliberation the Corporation offered only £600; that it was accepted by the present holder of the office, and that the Board, having regard to its usual practice of declining to consider proposals to increase salaries until five years have elapsed after appointment, on the ground that the fixing of a low initial salary would tend to limit competition and discourage eligible candidates, feels unable to concur in the present proposal of the Corporation. A strong resolution of protest was passed by the Committee.

EPIDEMIC OF SCARLET FEVER IN LURGAN.

A serious epidemic of scarlet fever broke out in Lurgan about April 10th. In a week it had assumed considerable dimensions, and soon some 50 cases were in hospital, and the empty small-pox wards were called into requisition. In addition to the fever there were a large number of septic throats, some of which proved fatal. The medical officer of health (Dr. Agnew) thought the spread of the disease due largely to giving out work from one or two factories, but many cases have followed the distribution of milk from one dairy. The utmost efforts have been made to cope with the trouble.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

VITAL STATISTICS OF SCOTLAND.

THE fifty-fourth annual report of the Registrar-General for Scotland, covering the year 1908, has just been issued. The more outstanding facts of the vital statistics of Scotland for the year are a low birth-rate, a low death-rate, and a low marriage-rate.

The forty-fourth annual report on vaccination is of special interest in that it shows the effect of the recent Vaccination Act, the Act which permits the conscientious objection of the parents to be a valid excuse for the non-vaccination of children. The result of the Act is found to be that a decidedly larger number of children escaped vaccination than was previously the case.

The population of Scotland at the middle of 1908 is estimated to have been 2,826,587 males and 2,538,258 females. The total population is estimated to have been 50,524 more at the middle of 1908 than at the middle of 1907, the male population being estimated to have been 26,351 more, and the female population 24,173 more. These estimated increases of population are based on the rates of increase observed in the last intercensal period, which rates are assumed to have continued since the last census. The natural increase of the population of Scotland, the excess of births over deaths from the middle of 1907 to the middle of 1908 amounts to 52,875. The difference between that figure and the estimated increase may be taken as the indication of the probable effect of immigration and emigration. The natural increase of the male population between the middle of 1907 and the middle of 1908 was 28,129, and of the female population was 24,746.

The total number of births registered in Scotland during the year 1908 was 131,337, which is 2,548 more than the number of births registered during the previous year, but is 329 less than the average number of births registered annually during the previous five years, and 242 less than the average number of births registered during the previous ten years. The birth-rate of the year is 27.21 per 1,000, a rate which is 0.24 above that of the previous year, but is 0.95 below the mean of the rates of the previous five years, and 1.69 below the mean of the birth-rate of the previous ten years.

The total number of deaths registered in Scotland during 1908 was 77,849, a number which is 572 more than that of the deaths registered in the previous year, 1,555 more than the average number registered annually during the previous five years, but 136 less than the average number registered annually during the previous ten years. Compared with the deaths registered in 1907, those registered in the principal towns show a decrease of 618, and those in the insular rural districts a diminution of 92; but those registered in the small town districts show an increase of 774; those in the large town districts an increase of 298; and those in the mainland rural districts an increase of 210. The death-rate for the year is 16.13, a rate which is 0.05 less than that of 1907; 0.18 less than the mean of the death-rates for the previous five years; and 1.01 less than the mean of the death-rates for the previous ten years. Marriages registered in Scotland during 1908 numbered 31,583, which is 167 less than those registered in the previous year. The marriage-rate for the year was 6.54 per 1,000 of the estimated population. It is the lowest rate of any year since 1888.

The combined statistics of eight of the principal towns show that in them the birth-rate was lower than that of the previous year, which was the lowest previously recorded for those towns; the death-rate being for the first time less than 17 per 1,000; and the marriage rate being the same as those of 1886 and 1887, which were the lowest previously recorded. The death-rates of the year in the towns of Edinburgh, Aberdeen, Paisley, and Greenock are found to be the lowest recorded.

The number of children successfully vaccinated during 1908 was 98,642, amounting to 75.14 per cent. of the total children, and to 82.98 of the children alive at the time of vaccination. The former percentage is 7.59 lower than that of 1907, and 8.91 lower than the mean percentage of the previous ten years. The latter percentage is 8.47 lower than the rate of the previous year, and 10.31 lower than the mean of the percentage of the previous ten years. Both the percentages are the smallest yet recorded.

UNIVERSITY OF EDINBURGH: HISTORY OF MEDICINE.

Dr. Comrie's fifth lecture was devoted to an examination of the works of Hippocrates (born 460 B.C., died about 350 B.C.). The "Corpus Hippocraticum," he said, was composed of sixty distinct parts, of which sixteen were authentic works; some were possibly written in the School of Cnidos. Galen made many commentaries upon it. An essay in the course of the writings was called "Ancient Medicine"; another refers to "Airs, Waters, and Places," and dealt specially with the climate of Libya. In the course of the latter Great Britain was called the tin islands, about which Hippocrates stated he knew nothing. The need for very accurate observations and descriptions was insisted upon in connexion with the medical arts. The classical quotation concerning the "facies Hippocratica" as a sign of death was adduced as a well-known example to be copied. Empyema following pleurisy was to be diagnosed by the indications of varying pain in the chest, persistent purulent sanguineous expectoration and fever, not marked, but greater in the evening than in the forenoon. The therapeutics of pleurisy comprised the use of hot barley water following thorough evacuation of the bowels; limited doses of oxymel of squills (an Egyptian remedy), with honey and hot water as a beverage; local applications of hot water on sponge, in a bottle or in vessel of bronze or earthenware, to soothe the pain and induce comfort. Wine seemed often to have been prescribed. Purgatives consisted of euphorbia or hellebore with anise, cumin, or asafoetida. In pneumonia hot baths were recommended, and soft sponges used to lessen risk of injuring skin surfaces. The patient had to rest and have everything done for him. The notes of methods of treating pneumonia and case-taking were of value in indicating how accurately observations were made.

"Epidemics" referred possibly to an outbreak of Malta fever occurring after the Peloponnesian wars.

The "Aphorisms" had been translated into many languages, and commented upon by many writers and speakers—for example, Life is short and art is long. Experience was fallacious and judgement was difficult. Symptoms rather than morbid anatomy were dwelt upon in diagnosis, and in treatment great objection was made to so-called fattening processes. Bronchitis, pneumonia, coryza, and pains in the chest were diseases of winter. Tetanus was common in Greece, and had two distinct varieties—a very acute and fatal, and subacute and non-fatal variety. Epilepsy beginning before the twenty-fifth year of age was curable. Phthisis was said to be more common in the young than in the old—a statement which might be compared with the modern dictum which was that phthisis killed at about the age of 40 years. Eunuchs did not suffer from gout or baldness.

All starting the study of medicine were supposed to subscribe to the "Oath of Hippocrates," which was read in full; its high level of idealism was carefully insisted on. Reference was made to the work called the "Law," or a "Standard of Medicine" (Hipp., *De Juristic*). Epilepsy, fractures of skull and of forearm (radius) were described; treatment was indicated and comparisons were drawn between former methods and the modern use of massage and bandages.

A lantern demonstration included photographic representations of a bust of Hippocrates, many ancient surgical instruments and splints, and ladder used in treating disease of the spine with deformity, and a flat bed made of boards capable of being moved in two directions parallel to fixed supports running at right angles to the boards, trephining instruments worked with bow and string, or Archimedian screw, scalpels, dissector, and aneurysm needle. Authorities for statements made were indicated, and a copy of a dissector depicted, which was made of brass and steel, was handed round for inspection.

PHYSIQUE OF GLASGOW CHILDREN.

At the last ordinary meeting of the Royal Philosophical Society, Dr. A. S. Macgregor contributed an interesting paper on the physique of children admitted into Belvedere Hospital in the year 1907-8. The inquiry dealt chiefly with children under the school age, and investigated certain aspects of the relationship between the physical condition and the standard of the home life. For this purpose the number of rooms in the house was chosen as a convenient economic standard. Each social class has its own standard of physique, and the difference

between the standards for the poor and better-off children was distinct at all ages, but was particularly marked during the period prior to school life. The influence of poor conditions of life was most noticeable between the ages of 2 and 4 years, and there seemed to be some recovering of physique about the period when school life begins. The chief criterion of physique adopted was the height measurement, as the weight tended to diminish during the incubation periods, especially in the younger children. Using the increase in height and weight during the residence of the children in hospital as a test of the capacity to respond to better surroundings, he found that the slum children were quite amenable to improvement. The prevalence of rickets was emphasized. It was found in 31 per cent. of male and in 26 per cent. of female children. It occurred almost as often among the dwellers in the top flats as in those on the ground floor, but the incidence markedly diminished as the population of rooms in the house increased. It was also noted that rickets seemed to be twice as common among Glasgow children as among those from other parts of the country, and seemed to be more common among the children of mothers born in Glasgow than of mothers bred out of Glasgow.

EDINBURGH POST-GRADUATE VACATION COURSE IN MEDICINE.

The syllabus for the Edinburgh post-graduate vacation course in medicine has been issued. The course will extend from Monday, August 30th, to Saturday, September 25th, and will comprise: (1) A general course; (2) a surgical course; (3) special courses; (4) each day a special lecture on some subject of general medical or surgical interest. The University Union will be available to graduates of any university during the month of September for a fee of 5s. During the past three years some 70 graduates have, on the average, attended the post-graduate courses. In order to prevent disappointment, graduates who wish to enter for the surgical course or any of the limited classes are requested to study the syllabus carefully, and to fill up the entry form at an early date to the Secretary. Places will be reserved only if applications are accompanied by the fees for the classes in question. The classes are open to women. Communications should be addressed to the Secretary, the Faculty Office, University New Buildings, Edinburgh.

ROYAL INFIRMARY, GLASGOW.

After a keen contest, the post of Pathologist to the Royal Infirmary, vacant by the resignation of Dr. Galt, has been filled by the appointment of Dr. J. H. Teacher, M.A., M.D., who for some time has acted as senior assistant to Professor Muir. Since 1905 he has been Assistant Pathologist to the Western Infirmary and to the Royal Infirmary for Sick Children, and for the past two years has held the position of Lecturer in Pathological Histology at the University.

CEREBRO-SPINAL MENINGITIS IN SCOTLAND.

The Registrar-General for Scotland reports that in eight of the principal towns of Scotland, during the month of March, deaths from cerebro-spinal meningitis numbered 12. This was 4 more than in February, but 15 fewer than in March, 1908. Of these 12 deaths, 9 were registered in Glasgow, 2 in Edinburgh, and 1 in Aberdeen.

NURSES' REGISTRATION.

The Central Council of the British Medical Association, at its meeting on April 28th, adopted resolutions expressing the opinion that it is desirable that the general principle of separate registration of nurses in Scotland, as embodied in the bill introduced into the House of Commons by Mr. Cleland to establish and make regulations for a register of nurses in Scotland, should be supported; and, further, that any bill which does not provide for reciprocity of registration within the United Kingdom should be opposed.

EDINBURGH INDIAN MEDICAL SERVICE DINNER.

This annual dinner will take place on Friday, May 28th, in the Caledonian United Service Club, Shandwick Place, Edinburgh, at 7.30 p.m. Tickets, 8s. each (exclusive), may be obtained from Colonel James Arnot, 8, Rothesay Place, Edinburgh. Sir Alexander Christison, Bart., will preside.

SCOTTISH DENTAL ASSOCIATION.

The annual meeting of the Scottish Branch of the British Dental Association was held in the Dental Hospital, Edinburgh, on April 24th, Mr. W. Taylor, L.D.S., Glasgow, in the chair. The following office bearers were elected for the ensuing session: President, J. Douglas Logan, L.D.S.; Vice-President, R. Keith Common, L.D.S.; Treasurer, D. Baillie Wilson, L.D.S.; Honorary Secretary, L. C. Broughton-Head, M.B., L.D.S.; new Members of Council J. P. Crichton, L.D.S., A. K. Finlayson, L.D.S., C. E. Page, L.R.C.P. and S., L.D.S., W. Taylor, L.D.S. The annual dinner was held in the Caledonian Station Hotel the same evening, under the chairmanship of Mr. J. Douglas Logan, L.D.S., Edinburgh. The toast of "The Royal Colleges of Physicians and Surgeons of Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow" was proposed by Mr. W. T. Finlayson, L.R.C.P. and S., L.D.S., Edinburgh, and responded to by the Presidents of the respective bodies. "The British Dental Association" was proposed by Dr. McKenzie Johnston, and replied to by the President of the Branch, Mr. J. Douglas Logan.

British East Africa.

It is not often that we can accuse our Government departments—the Colonial Office, the War Office, or the Treasury, on which both are largely dependent—of erring on the side of generosity or liberality towards their employees; but for rank cheeseparing we can find nothing to equal a Colonial Office regulation recently promulgated which ruled that officials serving in British East Africa were to be limited to ten days at one time, and to twenty-eight days in the year on the sick list from illness, after which periods such officials were to be placed on half pay. We have it on very good authority that when the regulation was ordered to be incorporated in the Provincial Gazettes in British East Africa, the commissioner of at least one province (owing to its notorious unhealthiness) protested against the regulation, if he did not absolutely refuse to promulgate it locally. The regulation which was considered prejudicial to the interests of the officials employed was made the subject of a question in Parliament by the late Mr. Arnold-Forster, who asked the Colonial Secretary whether such a regulation had been issued and incorporated in the Provincial Orders throughout British East Africa. The reply by the Colonial Office was that such a regulation had recently been issued; but the Secretary of State has approved of its withdrawal, and in future a maximum of forty-five (45) days' sick leave per annum would be allowed.

Two points in regard to this regulation may be discussed: (1) Does the modified order go far enough—that is, is it fair or liberal? and (2) What can have been, or is, the reason for the action of the Colonial Office in this matter of sick list periods?

An official's illness may be due to his own negligence, stupidity, or excess, and not to climatic conditions. If the sickness be due to any of these conditions, cannot the Medical Board or the medical certifying officer who draws up the case be trusted to state the facts? As a rule—at all events in the War Office—both the authorized Medical Board and the medical officer drawing up the statement of an officer's case are called on to reply to specific questions dealing with causation; in the former case the Medical Board has to state whether the disease or disability is caused "*in and by the service*," while if the medical officer draws up the case he has to state what the "*habits*" (temperate or intemperate) of the officer are. It is thought that the recent order will make officials refrain from reporting sick, and thus increase the percentage of invaliding. As a matter of fact, officials are stopped 5s. a day every day they are in hospital, and this alone has tended to prevent their reporting sick. This tendency will become greater now that the recent regulation has come into force; though, let it be noted, officials in Northern Nigeria are deprived of the allowance of 5s. a day which was granted in their original appointments until officers were provided with brick houses. They paid 5s. a day when in hospital, and were provided with everything. The allowance of 5s. has been reduced yearly by 1s. and will cease altogether

next year; but officers will have to pay 5s. a day in hospital, and in stations where there is no hospital they have to pay for medical comforts. Most of the officials are living in mud houses. There should not be, we think, any charge for hospital treatment or for hospital comforts in non-hospital stations. The conditions of life in bush stations are much as they were eight years ago, and the climate has not altered.

Some facts with regard to vital statistics, hospitals, climate, public health, and sanitation in the East African Protectorate may not be out of place here. We find from the last report, 1906-7, presented to both Houses of Parliament, June, 1908, that a census had not only never been undertaken, but under present conditions would be quite impossible. An approximate estimate gives the population of the Protectorate at 4,000,000. Despite the mortality from sleeping sickness in the lake shore and an abnormally high infant mortality, the native population should tend to increase as internal peace is secured. The white population is roughly estimated at 1,600, including Government officials; it includes individuals to whom land, industrial, and mining concessions have been granted locally.

In 1906 the registration of births and deaths of Europeans, Americans, and Indians throughout the Protectorate, and of all deaths, including natives in township areas, became compulsory. The registration of native births is optional, so that the returns of births and deaths cannot be compared with a view to ascertaining the increase or decrease of population. Moreover, the native deaths registered form only a very small proportion of the total population. The returns, then, for 1906-7 show a total of births 190, deaths 1,347. It is unnecessary to give the figures for each province, but it may be stated that the province of Seyidie contributes 139 births and 770 deaths to the aggregate numbers.

There are European Government hospitals at Mombasa and Nairobi; in the former 23 patients were admitted, of whom 15 were cured, 5 relieved, and 3 died—that is, 13 per cent.; in the latter, of 52 admissions 26 were cured, 19 relieved, and 6 died (11.5 per cent.). There is no lunatic asylum in the Protectorate, but provision has been made for the erection of an asylum at Nairobi; natives are confined in the gaol and Europeans placed under medical supervision and sent home as soon as possible.

The description of the climate may be given by divisions of the Protectorate into three principal zones; but even thus there are considerable ranges in temperature and rainfall which have strong influences on health.

The coast region gives a temperature not excessive, but owing to the moisture of the atmosphere the heat is trying to Europeans. In the coast towns, however, during the monsoons a cool breeze blows constantly, particularly between May and November, when the south-west monsoon is prevalent. The hottest season is in January, February, and March; but the nights are generally fairly cool, though during the lull between the monsoons they are apt to be very oppressive. Most rain falls during April, May, June, and November. The climate of the coast stations for Europeans is apt after long residence to cause enervation, but on the whole is not unhealthy. Malaria and other tropical illnesses are not frequent. Inland the heat, being untempered by sea breezes, is less bearable.

The highlands of East Africa consist of ridges and plateaus ranging from 4,000 to 9,000 ft. high, one peak (Mount Kenya) reaching 18,000 ft. The climate here is generally speaking healthy. The sun so near the equator is powerful during the midday hours, but the air is brisk and invigorating and the nights cool, so that Europeans can exert themselves to an extent impossible at the coast. As this part of the country is considered suitable for colonization many settlers have made their homes in it. Children who have been born and brought up in it have a healthy appearance. The one drawback is the unduly great daily range of temperature and a prevalence of strong winds.

The third zone is the district round Lake Victoria. The shores of the lake are comparatively low-lying, and the heat consequently approaches and even exceeds that of the coast. Violent storms are frequent, and the climate is less agreeable than in any other part of the Protectorate.

Malaria is common, and, if not carefully treated, leads not infrequently to blackwater fever. Mummies and Kisumu have distinctly bad records in this respect, though some improvement in the accommodation and sanitary conditions of the latter station has rendered it less unhealthy. The general sanitary condition of the Protectorate falls short of modern ideas. Some improvement has been made at the Government stations as regards the control of water supply, clearing bush, etc., but progress is slow. The water supply from the lake (Victoria Nyanza) is very unsatisfactory, and has been the cause of a large increase in the number of deaths from dysentery. Steps have been taken to improve the supply by the erection of water tanks. Night soil at Nairobi is buried in trenches situated at some distance from the town. Drainage is insufficient. Kisumu has a similar system of conservancy to that of Nairobi. The public health has on the whole been good, though there was a marked increase in the prevalence of malarial and blackwater fever in the districts near Lake Victoria corresponding with an unprecedented rise of the lake level. Only one European official died during the year of the report, and two were invalided. The death was due to blackwater fever. The total mortality among the white population amounted to 13, or about 6 per 1,000. Sleeping sickness claims a large number of victims. Plague broke out at Nairobi during the year of the report, causing 26 deaths out of 31 cases. At Kisumu there was a slight epidemic. Three cases of enteric fever occurred at Nairobi, of which 2 were fatal. This proves the existence of the disease in the Protectorate; no authentic cases had previously been known. The most prevalent diseases (as in former years) were those of the respiratory organs, especially pneumonia and pleurisy, and of the digestive system, which showed a considerable increase over 1905-6. It must be noted that these remarks apply to cases dealt with in hospitals, and concern only a small proportion of the total population.

Special Correspondence.

BERLIN.

Discussion on Anaesthetics at the German Surgical Society. —The Care of Crippled Children.—The Board of Insurance and Tuberculosis in Workmen's Homes.

THE thirty-eighth annual meeting of the German Surgical Society, which took place in Berlin from April 14th to 17th, under the presidency of Professor Kümmel (Breslau), occupied itself with an immense number of subjects, for the most part highly specialized. One entire sitting, however, was given up to Narcosis, and the advantages and disadvantages of modern methods as compared with chloroform and ether. Neuber (Kiel) gave the result of the inquiry sheet sent to all German surgical specialists. Out of a total of 71,000 narcoses, 21 deaths were recorded, or 1 in 3,000. The number of cases in which chloroform was the anaesthetic used had gone down from 75 per cent. of all administrations to about 25 per cent. The outcome of his own experience, said Neuber, pointed to scopolamine and ether as the least dangerous of anaesthetics. Bier (Berlin) pleaded for spinal anaesthesia in cases in which general narcosis might be risky. His favourite local anaesthetic was novocaine-adrenaline. For short operations in cases in which local anaesthesia was out of the question, Sudeck (Hamburg) recommended ether combined with morphine. Rehn (Frankfurt) discussed the deleterious influence on the spinal ganglion cells and medullary fibres of the anaesthetics injected into the spinal canal. Kader (Krakau) had found spinal analgesia safe and successful if carried out with a full dose of tropacocaine. Erhardt (Königsberg) recommended a mixture of gum (arabinc acid) as favouring slower absorption of the anaesthetic by the medullary sac. Koehler (Berlin) was strongly opposed to the introduction of spinal anaesthesia into field surgery.

Much attention has been given of late to questions connected with the care and education of needy child cripples in Germany. Though private initiative has been active for many years, and though the different Federal States have made a certain amount of provision for these little

sufferers by establishing cripples' homes, polyclinics, etc., these measures have not been nearly far-reaching enough, and fully organized and general action is urgently necessary if the question is to be dealt with thoroughly. Accordingly, after the usual preparatory steps, an influential German Union for the Care of Cripples has been formed. It numbers among its members Ministerial-director Foerster and Geheimer Medicinalrath Dietrich (both of the Prussian Cultus Ministry), delegates from the Bavarian and other Federal State Ministries; orthopaedic surgeons of note, mayors, town councillors, clergymen, heads of schools, and some well-known philanthropists—forty-eight persons in all. The first meeting was held in the large hall of the Prussian Cultus Ministry on April 14th, and was attended by many of the German orthopaedic surgeons who had come to Berlin for the surgical congress. Broad general lines of action were arranged, special stress being laid on prophylactic measures. The work of the meeting was, of course, mainly preparatory.

New measures for the protection of working men and women against infection from tuberculous comrades have just been started by the Berlin Branch of the National Board of Insurance. In future all the Berlin sick clubs affiliated to the Board will report to it their tuberculous cases, and the homes will thereupon be visited by special medical officers. On their recommendation the homes will be disinfected or thoroughly cleansed, or rearranged in as hygienic a manner as circumstances permit. If the patient cannot afford the expense of a separate bed, one will be provided; a separate room even will be rented for the patient where this seems of vital importance. The uninsured members of the family, too, will be examined medically, and if found tuberculous will be put in communication with the city bureaux for the care of the needy tuberculous population. Onerous and expensive as these measures must necessarily be, they are primarily designed, and no doubt in the end will prove, to effect a considerable saving of money to the National Board of Insurance. No fitter illustration could be given of the great truth that national health means national prosperity.

Correspondence.

TETANUS OCCURRING AFTER SURGICAL OPERATIONS.

SIR,—I am able to add three cases to those recorded by Mr. W. G. Richardson in the JOURNAL of April 17th last.

CASE I.

A woman, aged 45, on whom I performed subtotal hysterectomy for fibroid growths on April 12th, 1908. The wound healed by first intention, and all went well till April 29th, when stiffness of the muscles of the jaw and throat, with rise of temperature occurred. Generalized spasms were absent, but local stiffness and spasm persisted, with inability to swallow and pyrexia, up to 102° F. The patient rapidly became weaker, and died on the fifth day of the illness. No post-mortem examination was obtained, and the wound having been completely healed, there was no discharge available for bacteriological examination.

CASE II.

A man of strong physique, a tram driver, was admitted into the South Devon and East Cornwall Hospital on April 21st, 1908, with a double bubonocoele of five months' duration, under the care of Mr. Whipple, to whom I was at the time assistant surgeon. I performed radical cure on April 25th, and all went well till 2 p.m. on April 30th, when the patient complained of difficulty in opening his mouth, and pain in the back of the neck. The symptoms increased rapidly in severity during the afternoon and evening, and at 12.45 a.m. 20 c.c.m. of tetanus antitoxin was administered hypodermically. The temperature was then 99° F., and pulse 112. No improvement followed, and the patient died in a spasm at 8 a.m. on April 31st. The wounds had healed almost completely.

CASE III.

A shipwright, aged 24, of healthy appearance, was admitted to the South Devon and East Cornwall Hospital on April 21st, 1908, under the care of Mr. Whipple, for a left inguinal bubonocoele of two years' duration. On April 28th I performed radical cure. The wound suppurated but was completely healed by May 10th, the temperature never rising above normal. On May 16th the patient complained of inability to open his mouth, and there was stiffness of the jaw and neck muscles. The disease developed fully, and ran a protracted course, the temperature rising to 103° and 104° F. for twenty-three days.

It then fell gradually, and was normal on the twenty-sixth day of the disease. The patient eventually recovered completely. Chloral and bromide mixture and serum injections were frequently used.

These three cases are very suggestive. In all both myself and my assistants wore boiled rubber gloves, and observed all other antiseptic precautions. In two of them union of the wounds occurred. At the time I suspected the catgut, which was in each case obtained from the same source, and prepared in the hospital by the same method—that known as the iodine spirit. On referring to the clinical pathologist's report of the examinations of catgut, I find that there is no record of bacteriological examination of catgut between March 14th and May 22nd, 1908.

In Case II (which died) cultures were taken from the wounds in the groins *post mortem*, and the result is noted as follows:

Culture from right wound shows growth of shortish thick bacilli, from left shows staphylococci. No tetanus bacilli seen.

I am much indebted to Mr. Richardson for his interesting paper.—I am, etc.,

H. W. WEBBER,

Plymouth, April 25th.

Surgeon to the South Devon Hospital.

ANAPHYLAXIS.

SIR,—Discussing the term "anaphylaxis" in his interesting letter published in the JOURNAL of April 24th, p. 1037, Dr. W. Calwell finds a difficulty in the fact that repeated injections of antidiphtherial serum lead to serum anaphylaxis, or increased susceptibility to serum, but do not at the same time induce diphtheria anaphylaxis, or increased susceptibility to diphtheria.

Serum anaphylaxis results from repeated injections of an antigen, or antibody-producing substance, which is present in normal and antidiphtherial horse serum alike. The other active agent in antidiphtherial serum is diphtheria antitoxin, which does not cause diphtheria anaphylaxis. In order to produce diphtheria anaphylaxis it is necessary to give repeated doses of diphtheria toxin. This was done, for example, by von Behring and Kitashima; an animal treated by these observers died as the result of a series of injections of diphtheria toxin, amounting in sum to $\frac{1}{100}$ of the minimum lethal dose.

The whole problem is somewhat complicated by the circumstance that toxin anaphylaxis is induced by material which is poisonous at the moment of injection, whereas serum anaphylaxis is elicited by substances which are bland when first introduced into the system. Doses of toxin act speedily; but horse serum when first injected into the human subject takes effect, as a rule, after the lapse of a latent period. The principle, however, is similar under both conditions. Briefly, both serum anaphylaxis and diphtheria anaphylaxis are produced by antigens, serum antigen in one case, diphtheria antigen, or toxin, in the other. Serum antigen and diphtheria toxin are substances of a different order from diphtheria antitoxin, which is an antibody. It is not, therefore, to be expected that antidiphtherial serum, which contains serum antigen and diphtheria antitoxin, should act as if it contained serum antigen and diphtheria toxin—in other words, should cause at the same time serum anaphylaxis and anaphylaxis to diphtheria.

The term "anaphylaxis" is in common use on the Continent. The word *Ueberempfindlichkeit* is also employed by von Pirquet and Schick, Otto and others. Writing in this country I have used the word "supersensitization" to denote the condition under notice, and this expression has also been adopted by Dr. E. W. Goodall. It is preferable to "hyperimmunization," a word which neither represents the facts of the case nor conforms to the canons of etymological purity.—I am, etc.,

Chester, April 26th.

J. R. CURRIE.

COAGULATION TIME OF THE BLOOD.

SIR,—Dr. Addis's observations in the BRITISH MEDICAL JOURNAL of April 24th, p. 997, on this subject have been so numerous, and are so uniform in their results, that it is difficult to withhold assent from his conclusion that calcium and citric acid respectively have no effect upon the coagulation time, but the estimation of this factor is so

extremely difficult that I venture to say a word of caution before the results are accepted as final. Some months ago I suggested in your columns a method of taking coagulation time, which is very simple, and appeared to be accurate. It did not include precautions against variations of temperature, which Dr. Addis shows to be very important, but this defect would not vitiate comparisons of times obtained at a single sitting. I have found that different portions of the same drop of blood may vary as much as 25 per cent. in coagulation time, and Dr. Addis has found some difference, for he warns us to reject the part last drawn, because it coagulates sooner than that which first appears. This does not agree with my results. I find that coagulation may begin in the part last drawn, or in the part first drawn, or in any intermediate part, and that adjacent parts do not by any means follow one another in order. Dr. Addis finds a difference of 33 per cent. in coagulation time among 150 trials on different days. I have found a difference of 25 per cent. in different parts of the same drop, a difference of 40 per cent. in different drops taken within half an hour of each other, and a difference of 50 per cent. in drops taken before, and half an hour after, a meal. Dr. Addis does not record the relation of his observations to meal times, but he is such a careful observer that we may take it for granted that this was considered. I do not wish to pit my method against his. It is quite possible that his is the more accurate—certain that it is more accurate in respect of observations taken at different temperatures; but the normal margin of error is so wide, even on his own showing by his own method, that one would expect a wider variation in his results, which are quite remarkably uniform. If they are confirmed they are of great importance, but they are scarcely yet conclusive. I should say that the results that I have herein recorded are founded on some hundreds of observations.—I am, etc.,

London, April 26th.

CHARLES MERCIER.

HUNGER PAIN AND DUODENAL ULCER.

SIR,—The "hunger pain" controversy interests me "too" much. I have "hunger pain," and am suffering from operative nightmare. At the same time, if I am to be promised relief from what apparently is duodenal ulcer, I shall gladly lay me down to be relieved by gastro-enterostomy. But there are one or two points that may interest your controversialists. Let me therefore be personal. I have suffered from "hunger pain" since I was 16 years of age; at least, the gnawing pain of then and that of to-day are indistinguishable. A drink of water, hot milk, or an apple or biscuit immediately relieve the pain. Sodium bicarbonate has an equally good effect. The tenderness is appreciable below the ensiform cartilage and to the right of the rectus muscles. I never have had sickness nor melæna. Pain ensues three and four hours after food. Tea in excess is certain to cause pain. After freedom from pain for a few hours, a cigarette (I inhale) will at once call the pain into being. When I am troubled with this "hunger pain" my sleep is seriously broken, and between 1 and 3 a.m. I am compelled to take soda and water. This stills me to sleep at once. I now and again swallow $\frac{1}{2}$ grain of morphine, but I hate the stuff. It acts like magic, and if I take it two days in succession the pain vanishes, and I have freedom for perhaps weeks. To look at me, I am the picture of health. I play golf, cricket, and love fresh air. I eschew meat and subsist on the sloppiest of diet. Yet this ore persists in reminding me that it is there about my pylorus.

If I have a few days of hyperacidity I know it is the danger signal of "hunger pain." If I go from home and accept food that I would never eat at home I may be attacked by biliousness. I become languid, my eyes become muddy, and in a few days on comes the "hunger pain." Clayey stools add to the list of my peculiar summary of symptoms. I am a busy man, and inclined to light-heartedness, but it takes the "stuffing" out of one to be tormented as I am. A friend of mine has recently submitted to the "knife"; he marvels at my patience since he feels a new man.—I am, etc.,

April 25th.

PYLORUS.

RESPIRATION AND FATIGUE.

SIR,—Dr. Leonard Hill, in his interesting letter on "arterial blood pressure before and after muscular exer-

tion," which appeared in the BRITISH MEDICAL JOURNAL (page 927), states that "the fatigue which follows an athletic feat seems to be mainly cardiac in origin, and it is due to want of oxygen."

Now, if the fatigue is due to want of oxygen—and Dr. Hill's many interesting experiments with that agent clearly prove this—inasmuch as it is through the lungs that the blood obtains oxygen, and as it is also by the aid of the respiratory movements that the normal endocardial pressure is maintained, a not unimportant factor in the adequate functioning of the heart, surely it is putting the cart before the horse to state that "the fatigue which follows an athletic feat seems to be mainly cardiac in origin."

That the acceleration of the heart-beat during exercise is not, as is pretty generally supposed, the primary cause of the distress, is proved, it seems to me, by the fact that after exercise, when distress is over and the respiratory act is performed rhythmically and easily, the pulse rate is still much in excess of the normal, and remains above the average for some time. So it is not unreasonable to suppose that the quickening of the circulation is an effort of Nature to aid in the oxidation and elimination of toxic products formed during exercise. In short, it is a protective measure. The process of oxidation would also account for the rise of temperature that is not infrequently associated with exercise.

The primary cause of distress following muscular exertion is due, I take it, to disorderly respiratory movements, which destroy the regularity of respiratory exchange; and the phenomenon of "second wind" bears out this view. The distress and more or less irregular, quick, shallow movements of the whole chest, which were before its advent a somewhat prominent feature, now give place to a feeling of well-being and regular, slower, deeper respiratory movements, which are chiefly confined to the lower zone of the thorax and upper part of the abdomen. A runner sometimes explains the loss of a race by the fact that he never got his "second wind." In other words, the mechanism upon which this phenomenon depends was not brought into operation. If the poor fellow had only known the muscular combinations which favour its development instead of trusting to luck, as only too often is the case, possibly the race might have been his.

It is true, Dr. Hill has pointed out, that the mechanism of respiration in an exhausted runner or boxer (and I may add also, in any one who suffers from failure of the respiratory powers, temporary or otherwise, be the cause what it may) is chiefly thoracic in character—a disorderly, vitiated type of respiration. Dr. Hill has also told us that in easy breathing the belly, rather than the chest, is used, which is a physiological necessity, seeing that the efficiency of the circulation is largely dependent upon the ability of the respiratory pump to keep the heart adequately filled, and the rhythmical squeezing to which the splanchnic area is subjected, when the diaphragm and abdominal muscles are properly used, makes for this most desirable end. But, it seems to me, he does not draw the logical and legitimate conclusion warranted by these facts—namely, that as long as the muscles governing the respiratory act efficiently perform their duties, other things being equal, breathlessness and fatigue cannot overtake one. In other words, given a sound heart, lungs, and other organs, the respiratory fitness of the individual is the true regulator of a work of muscular endurance. "There's the rub."

Those who have studied the subject find plenty of evidence as to the early deterioration of the respiratory powers in civilized man of to-day. Indeed, the evil is so widespread, that it is not at all uncommon to find signs and symptoms of it in those not yet out of their teens, and sometimes even in young children. This unfortunate state of affairs is not the result of civilization, but the consequence of the wilful rejection of the fundamental truths of physiology and hygiene. And medical men are as great offenders as the laity in this respect. Desires and customs, not necessity or reason, seem to be the principle upon which most of us plan our exercise, bathing, clothing, feeding, and other bodily arrangements.

However, even though man arranged to be guided by reason instead of whims and fancies and trained for an athletic feat in a rational manner (by "rational" I mean systematic practice in the correct use of the muscles

governing the respiratory act, in addition to training for the economical and efficient use of the other muscles concerned in the particular form of exercise), when the limits of individual endurance have been reached fatigue will necessarily supervene, but oxygen administered according to Dr. Hill's method will considerably delay its onset.

Athletes, as well as the medical profession, owe a debt of gratitude to the eminent physiologist for his researches on the use of that valuable agent, oxygen, which leaves the body better, unfatigued, unpoisoned by the unoxidized products produced in the excessive strain of great exertion. —I am, etc.,

Major, R.A.M.C.

Chatham, April 9th.

ARTERIO-SCLEROSIS.

SIR,—In the JOURNAL of April 10th, p. 904, in a review of Dr. Josué's work on arterio-sclerosis, I observe a statement that I have obtained aortic lesions similar to those following the intravenous injections of adrenalin "by swinging rabbits by their hind legs." In justice to my colleague, Dr. Klotz, may I point out that the experiments here referred to are his, not mine? I can only state that by periodic suspension of rabbits for a few minutes daily by their hind legs most advanced lesions can be produced, and that these observations of Klotz's will be found in detail in the *Centralblatt für Allgemeine Pathologie*, vol. xix, 1908, p. 535.—I am, etc.,

Montreal, April 19th.

J. GEORGE ADAMI.

RHEUMATISM AND APPENDICITIS.

SIR,—In the BRITISH MEDICAL JOURNAL of March 20th, Dr. J. A. B. Hammond records a case of appendicitis in a rheumatic subject which yielded rapidly to salicylic medication. Some months ago I had a case in which the clinical features were very similar to those described.

Miss S., aged 38, suffering from chronic rheumatism—"flying" pains, swollen joints, and stiff neck—came to me for a course of electricity and massage. Salicylates had been tried without much benefit, and I had it in my mind to place her on some form of intestinal antiseptic treatment, the breath being foul and the motions evil smelling. Within three days of my first seeing her, however, she developed what appeared to be a severe attack of appendicitis. A history of former similar attacks of a milder character was elicited, and so acute were the symptoms that it was deemed necessary to call in a surgeon. Immediate operation was advised, and the abdomen accordingly opened. The operator expected to find pus, or, at least, an ulcerated appendix on the point of perforation. Slight swelling and congestion was, however, all that was evident. In fact, the patient would almost certainly have recovered without surgical interference.

Now, the question arises, was the appendicular lesion due to the same cause as produced the joint troubles—that is, to the "rheumatic" toxin? In other words, was it of a kind which would never in any circumstances have gone on to suppuration? The marked effect of salicylates in Dr. Hammond's case would seem to indicate that such specific appendicitis may occur, but many similar observations are needed to establish its existence.

In any case, the association of appendicular trouble with chronic rheumatism is one more link in the chain connecting this latter disease with intestinal auto-intoxication. It is surely a plea for the treatment of arthritis deformans and kindred evils by a vigorous attack upon putrefactive organisms in the bowel, either by the exhibition of such drugs as creosote and guaiacol, or, better still in the opinion of many observers, by the introduction of suitable cultures of lactic acid-forming bacilli.—I am, etc.,

FRANCIS HERNIMAN-JOHNSON, M.B.,
Ch. B. Aberd., R.N.(ret.)

Bishop Auckland.

MR. JOHN DAVIDSON.

SIR,—Among the documents found since the disappearance of Mr. John Davidson was one in which he speaks of his inability to face the effects of cancer. His family wish, in the circumstances, to discover on what grounds he based his belief that he was suffering from this disease, and I write on their behalf to ask if you will allow me through your columns to request any medical man whom Mr.

Davidson consulted in the last few years to communicate with me at this address if he feels himself free to do so.—I am, etc.,

36, Roland Gardens, S.W., April 23rd.

GRANT RICHARDS.

HISTOPATHOLOGY OF THE VERMIFORM APPENDIX.

SIR,—On page 235 of the JOURNAL of January 23rd there is an editorial entitled Histopathology of the Vermiform Appendix, which is in the main an exposition of some of the more striking points contained in C. U. Maaløe's *Histopatologiske Studier over Processus Vermiformis*. (1908. Copenhagen: Lund.) Maaløe's work is not, unfortunately, available to me in Melbourne, and I am therefore unable to say whether this author has or has not acknowledged the work of his predecessors in this important field of science and surgery; but, as the general tendency of your note is to infer that Maaløe's points are something novel, I trust you will permit me, in justice to myself and to the school which I have now the honour to represent, to remind you that much of what you mention in your article has already been published by myself, both alone and in conjunction with others.

In April, 1906, I published, with Dr. L. A. H. Lack, nov of the Indian Medical Service, in the *Journal of Anatomy and Physiology*, page 247, vol. xl, an article entitled The Vermiform Appendix of Man and the Structural Changes therein Coincident with Age. This article is fully illustrated, and concluded as follows:

1. Lymphoid tissue is the characteristic feature of the true caecal apex throughout the animal kingdom, including man. As the vertebrate scale is ascended this tissue tends to be collected together into a specially differentiated portion of the intestinal canal, the vermiform appendix.

2. The amount of lymphoid tissue present at the caecal apex varies most probably, though not certainly, in accordance with the varying diet of the animal.

3. The vermiform appendix of man is not, therefore, either a vestigial remnant of an organ in a state of retrogression, but is an actively functional lymph gland. It is no argument against this view to state that because the appendix is frequently removed without any apparent functional disturbance it is useless, because the same argument might be adduced against the stomach, which is occasionally removed either wholly or in part, and with more or less success.

4. The appendix of man is not equally functional throughout the whole of life. At birth it contains practically no lymphoid tissue; within six weeks it has become a lymph gland, and continues as such during the first half of life, after which it progressively declines in functional activity. Lymphoid tissue is therefore a tissue of the growing animal.

5. Obliteration of the vermiform appendix is a pathological process.

6. The functions of the human appendix are the same as those of any other collection of lymphoid tissue in any other part of the body.

Of these six conclusions, the first three are the embodiment of my earlier work on "The True Caecal Apex, or the Vermiform Appendix; its Minute and Comparative Anatomy," published in the *Journal of Anatomy and Physiology*, vol. xxxv, p. 83, 1900-1. This paper was the result of an extensive examination on the caecal apex of the lower animals, and in due course was followed by the one already mentioned on the human appendix. In the interval between the publication of these two papers, Mr. C. B. Lockwood of London published some most important work on the minute structure and lymphatic drainage of the appendix, and this left Dr. Lack and myself free to investigate other points, which were precisely those which your article would lead one to infer are now first known as the result of Maaløe's work. Dr. Lack and myself demonstrated at Geneva in 1905, and published in 1906, everything that you now state Maaløe has done as regards the increase in the size of the follicles, their decrease, the individual variations in the same, the fact that the appendix is not an organ in process of disappearance, and the contravention of Ribbert's views as to obliteration.

At the request of the editor of the *Intercolonial Medical Journal*, I published in that journal in 1906 an epitome of my investigations on the vermiform appendix, a copy of which I now enclose; from this you will see that Ellenberger has also achieved similar views to Maaløe, but like myself at an antecedent period. A study of the chronological order of the publication of Ellenberger's, Maaløe's, and my own work will provide the reader with a singular example of scientific plagiarism, which, however

regrettable from the standpoint of mere personal vanity, is in the interests of scientific truth invaluable, as it proves most conclusively my contention of 1900 "that the vermiform appendix of man is not a vestigial structure, but is, on the contrary, a specialized part of the alimentary canal," to be absolutely correct.

You will, Sir, I feel sure, believe me when I say that I write in no carping or antagonistic spirit, but merely in the interests of truth and justice. The former, we are assured, is great and will prevail; the latter is not infrequently blind.—I am, etc.,

RICHARD J. A. DERRY.

Professor of Anatomy, University of Melbourne.

February 24th.

"ANTIVIVISECTION AND WOMAN SUFFERAGE."

SIR,—Of course, having the evidence in my hand at Bristol, I said that the inspectors "were never instructed to make surprise visits." To suppose and suggest as you do that I should misquote evidence all the world can procure and read for themselves for no reason whatever is simply silly. For what I actually said, or what I was reported to have said form an equally authentic basis for the conclusion at which I was inviting the meeting to arrive—namely, that the inspectors were instructed by the Home Office to be inefficient.—I am, etc.,

Greywell, April 25th.

STEPHEN COLERIDGE.

* * * We have furnished proof that Mr. Coleridge did in fact misquote the evidence as to inspection given before the Royal Commission; and he does not deny the accuracy of the report on which we founded the indictment. We are willing to believe that this may have arisen from a misunderstanding of its import; but even if Mr. Coleridge sees no distinction between his allegation that inspectors are "told never to make surprise visits" and the evidence of Sir James Russell that he had never been instructed to make surprise visits, it must be obvious to persons of clearer mental vision that there is a vital difference between the two statements. Mr. Coleridge says it is silly to suggest that he misquotes "for no reason whatever." We agree that this would be silly, but we have made no such suggestion. It would be as easy to give a reason for his misquotation of this particular phrase as it would be to give one for his suppression of the statement made by Sir James Russell—in reply to the very next question (533)—that he very rarely gave notice of his intention to visit. Mr. Coleridge is also careful to say nothing about the other misstatement with which we charged him—namely, that the inspectors told the Commissioners in cross-examination that they never made surprise visits to laboratories. For this also a reason could readily be assigned. As for the "detective" method of inspection which Mr. Coleridge blames the Home Office for not adopting, we should have thought that the experience he has had of it would have been sufficient to convince him of its unsatisfactory results.

JEWS AND ALCOHOLISM.

SIR,—I have read the article in the BRITISH MEDICAL JOURNAL under the above heading with considerable interest, especially the paragraphs referring to the infantile mortality among the Jews. I am in a position to add to the facts mentioned there a very striking one which came to my knowledge recently when preparing a paper on the subject. Whilst the infantile mortality in Manchester in 1907 was generally 147.4 per 1,000, that of Ancoats was 188, and that of Cheetham 91. The latter district is inhabited to a very large extent by Jews of the poorer class, whilst Ancoats has very few Jews. The two districts are close to one another; in fact, one ends where the other begins, and they have practically the same geological and climatic conditions, yet the one with the large Jewish population has an infantile mortality less than half that of the other. That this is not merely a coincidence is proved by the figures for the year 1906. They were respectively 169, 203, and 94. Dr. Niven, medical officer of health, thinks the cause lies largely in the fact that most Jewish mothers suckle their children, and I agree with him. One seldom sees bottle-fed children among the poorer Jews, but, on the other hand, mothers belonging to the well-to-do classes rarely suckle

their babies. I have no doubt that this fact more than any other accounts for the greater resistance to disease shown by the bulk of Jewish children, though the temperance of their parents and the rarity of syphilis are not altogether negligible quantities.

I have no statistics referring to the infantile mortality among the different sections of the Jewish people, but my experience makes me incline to the belief that, roughly speaking, it is comparatively higher among the well-to-do.—I am, etc.,

Manchester, April 20th.

J. DUBERG.

The Services.

ARMY MEDICAL SERVICE.

THE ALEXANDER PRIZE.

The Alexander Memorial Prize consisting of £50 and a gold medal is awarded every third year to the writer of the best essay on a subject connected with military medicine, surgery, or hygiene.

The competition is open to executive officers of the Royal Army Medical Corps on full pay, with the exception of the professors and assistant professors of the Royal Army Medical College during their period of office.

No prize has been awarded for the triennial period ending December 31st, 1908.

The subject for the next prize essay is the following: "Tropical Abscess of the Liver." It may be treated either from a clinical or an etiological standpoint, and the essay must bear evidence of original observations. No essays should exceed 20,000 words, exclusive of tables, which may be added as appendices. Essays should be sent in to the Secretary of the Prizes Committee, Royal Army Medical College, on or before December 31st, 1911; each essay to have a motto, and to be accompanied by a sealed envelope bearing the same motto, and containing the name of the competitor.

CLASSIFICATION OF CASES.

COLONEL R. H. FOREMAN, P.M.O., Bombay Brigade, writes: In the JOURNAL of March 20th, 1909, p. 758, Colonel E. B. Hartley expresses a wish that the out-patient system should be adopted in the Imperial Army. It has been, officially, for five years back, and unofficially in many places for a score of years.

ROYAL ARMY MEDICAL CORPS (TERRITORIAL).

THE SECOND HOME COUNTIES FIELD AMBULANCE. UPWARDS of 150 members of the Second Home Counties Field Ambulance took part in a field day on Easter Monday. The sections represented were those of Canterbury, Ashford, and Whitstable, respectively commanded by Lieutenants Hollis and Barford, Lieutenant D. L. Hamilton, and Lieutenant W. H. Flint. The proceedings, which in spite of rain and wind were a great success, were under the general command of Major A. R. Henchley, of Canterbury, while Lord Lucas, Parliamentary Secretary of State for War, paid a visit to the scene of operations in the afternoon. In the evening there was a prize distribution in connexion with the corps, at which Major Henchley, supported by the Dean of Canterbury, Lord Lucas, Mr. Henchler Heaton, the Sheriff, and other notabilities, presided. On the conclusion of the speeches, there was a fencing display, and some tableaux representative of ambulance work on the field of battle.

SECOND LONDON DIVISION.

About 50 of the medical officers of the Second London Division of the Territorial Force dined together at the Café Monaco on April 22nd. Representatives of all the medical units and many of the battalions, as well as of the officers available on mobilization, were present. Among the guests were Sir Alf. Keogh, K.C.B., Director-General A.M.S.; most of the staff of the Second London Division, including Colonel Magill, C.B., staff officer to the A.M.O., and Colonel Oughterson, Secretary to the London County Association. Lord Esher, Lieutenant-General Sir W. H. Mackinnon, K.C.B., C.V.O., and Colonel Giles, V.D., A.M.O., First Division, wrote regretting their inability to accept invitations.

After the toast of "The King" had been duly honoured, the Chairman (Colonel Andrew Clark, V.D., Administrative Medical Officer) proposed "The Medical Services," and in the course of his remarks stated that all the medical units in the division were now nearly complete; great difficulty, however, was experienced in giving the necessary instruction, for which the men were very eager, owing to the inadequacy of the head quarters. With the exception of No. 4 Field Ambulance all the units were quite dependent on the good will of others for a place in which to drill and get their theoretical instruction, and, although the necessary equipment for instructional purposes had been granted, it was impossible to draw it, as there was no place in which to keep it.

The Director-General replied, and spoke of the original formation of the R.A.M.C. (Vols.) and their reorganization into Field Ambulances. He eulogized the progress of the medical units, many of them having great difficulties to

contend with, chiefly owing to the absence of head quarters: this was felt more in London than anywhere else. He also spoke of the importance of enlisting men for water duties in the various combatant battalions.

Colonel Hart, V.D., proposed "The Second London Division," and mentioned how much the medical officers were indebted to General Vesey Dawson and his staff for the instruction and assistance they had afforded.

Colonel Maude, C.M.G., D.S.O. (till lately General Staff Officer of the Division, now Assistant Director of the Territorial Force), who replied, spoke of the various arrangements that had been made for instruction, specially remarking on the course of lectures on sanitation delivered by the Divisional Sanitary Officer, Surgeon-Colonel W. R. Smith, V.D., which he and the other divisional officers had attended and appreciated.

Colonel Stephenson, C.B., V.D., Honorary Colonel of the R.A.M.C.(T.) Second Division, proposed "The Guests," to which Dr. Dawson Williams replied.

The formal proceedings closed with the toast of "The Chairman," proposed in a felicitous speech by Lieutenant-Colonel Lloyd-Williams.

After the guests had left a discussion took place as to the desirability of forming a Second Division mess, or of making a dinner in London an annual function. It was finally agreed that there should be an annual dinner of the division; and also that the First Division should be approached with a view to making it a joint dinner of the two London divisions.

The meeting broke up about a quarter past eleven, and it was generally agreed that it had been most successful and enjoyable thanks to the energy of Captain Jorman, Mess secretary of the Fourth and Fifth Field Ambulances, who had so ably organized it.

VOLUNTEER LONG SERVICE MEDAL.

THE Army Council has decided that the Volunteer Long Service Medal may be granted to all officers of the late Volunteer Force who were serving on March 31st, 1908 (when the force ceased to exist), and had then completed a total of sixteen years' service. This decision will apply to all officers, whether they have joined the Territorial Force or not.

Medico-Legal.

A MILK WARRANTY.

IN the Croydon County Court on March 16th, Dr. Harold Bentley was awarded damages against a firm of dairy farmers at Mitcham, who verbally contracted to supply him with nursery milk for his infant child, such milk to be drawn exclusively from Mitcham cows, to be unadulterated, and to be free from preservatives. While taking this milk the child became ill, and the court held that this illness was due to the presence in the milk of lactic acid, introduced into it by the defendants in breach of their implied warranty. The child, born at the end of December, 1907, was breast-fed until March, 1908, when it was put on cow's milk. As the first source of supply was not found satisfactory, the plaintiff looked elsewhere for milk, and eventually a verbal contract, of the effect already indicated, was entered into by the defendants through their manager. This warranted milk at first seemed to suit the child, but after a few weeks the child ceased to finish its meals, and began to fall off in condition and to suffer from intermittent attacks of diarrhoea. In August it was sent to the seaside for about a fortnight, and during this absence improved in health. On its return, use of the defendants' milk, as also of cream obtained from them, was resumed, and again the child grew ill. Finally, in September a specialist in children's diseases visited the child, and came to the conclusion that the milk used was in fault. Owing to the warranty received, this was not deemed probable, but nevertheless a sample of the milk was sent to an analyst for examination, and was reported to contain 0.03 per cent. of boric acid—an amount equal to about 5 grains in each pint. It was shown that the milk was sent to the analyst as received from the defendants, except for the addition of a little sugar of milk habitually taken by the child with its milk, and that though borax was used in cleaning the child's bottles, none of it could have got into the sample. The court held it unreasonable to believe that the boric acid was, as suggested by the defendants, derived from the sugar of milk, and it accepted the view that the child's symptoms were those of boric acid poisoning, and not of summer diarrhoea, as argued by the defendants. Furthermore, in weighing the denial of the defendants that they were responsible for the presence of the boric acid in the milk, the court accepted and kept in mind Dr. Bentley's statement that the defendant's manager—a man engaged all his life in the milk trade—had alleged, when challenged on the point, that not only had he added nothing to the milk, but he was not even quite sure what boric acid was.

Evidence was given by four medical men. Dr. Forsyth said he had seen the child on three occasions. Its symptoms were such as would result from boric acid poisoning, and the course of its illness was not consistent with a diagnosis of summer diarrhoea. Dr. E. Spriggs, who had been supplied with a clinical account of the child's illness, was satisfied that it was caused by boric acid in its milk. The same view was taken by Dr. Adams, of Croydon, who examined the child and its clinical history in January, after its recovery. On the

other hand, Dr. Kempster, of Battersea, who, on behalf of the defendants, investigated the matter likewise in January, held that it had suffered from gastro-enteritis and that it was due to "a combination of circumstances," and not to boracic acid poisoning.

In dealing with the question of damages, Judge Harrington said that, though it was important that milk supplies should be pure, it was well recognized that boracic acid was commonly used for the preservation of milk, and in small quantities was not deleterious; nevertheless, it was expressly agreed in this case that the milk should be free from preservatives, boracic acid being specifically mentioned. The plaintiff could not recover damages for the great anxiety which had been caused him, but he was entitled to the expenses entailed upon him. The child, who appeared in the case as joint plaintiff with its father, was entitled to something for the pain and suffering endured; but suffering endured by a child could not be considered in the same way as that of a person of mature years. Moreover, it had now completely recovered, and Dr. Bentley did not ask for substantial damages. Hence a sum of £5s. would be held to meet the case, the judgement being for this sum, in addition to £5 16s. 6d. (the expenses entailed on the senior plaintiff) and costs on B scale.

BONDS NOT TO PRACTISE WITHIN AN AREA.

BETA writes that he is under a bond not to practise within two miles of "A's" surgery. He is now desirous of purchasing a partnership with "B," whose surgery is nearly three miles from "A." Is he debared from visiting patients living within two miles of "A's" surgery?

"* If our correspondent has signed a bond not to practise within two miles of "A's" surgery, how can he legitimately visit patients within that radius? Such a proceeding would be a violation of his engagement, and subject him to the usual penalties.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following M.B. candidates have been approved in the subjects indicated:

PRELIMINARY EXAMINATIONS: *Mathematics*.—Sir W. E. T. Avery, Bart., University; E. L. Collins, non-collegiate; D. M. Ely, Exeter; C. G. Fannin, Exeter; E. H. Kennard, Exeter; W. R. Scott, New.

Mechanics and Physics.—L. H. D. Acland, Magdalen; Sir W. E. T. Avery, Bart., University; W. G. V. Blogg, Keble; R. B. Bourdillon, Balliol; R. A. Bull, Jesus; C. R. Bury, Trinity; C. H. Carlton, St. John's; F. B. Chavasse, Balliol; W. C. Collier, Balliol; W. J. Hart, Queens; E. F. A. Hay, Corpus Christi; J. W. Horan, Brasenose; J. A. Liddell, Balliol; J. M. D. Olmsted, Queen's; A. L. Parker, non-collegiate; N. M. Parsons, New; S. K. Ray, Exeter; G. T. Selby, New; R. G. W. Stark, non-collegiate; R. H. Sutcliffe, Merton; A. E. Swinton, New; H. A. Tozer, Jesus.

Physics.—H. E. A. Boldero, Trinity; R. W. J. A. Cushing, Marston's Hall; R. A. Fawcus, Oriel; L. Gameson, Queen's; F. C. Gladstone, Pembroke; J. J. S. Hill, Jesus; R. J. Inman, University; S. Jalland, Lincoln; E. R. Speyer, New; H. A. B. Whitehouse, Christ Church.

UNIVERSITY OF CAMBRIDGE.

C. L. BOULENGER, B.A., King's College, has been appointed Assistant to the Superintendent of the Museum of Zoology.

Application to occupy the University's Table in the Zoological Station at Naples should be made to Professor Langley before Thursday, May 20th.

Examination Results.

The following candidates have been approved at the examination indicated:

D.I.P.H. (Parts I and II).—J. H. Alkman, A. Brenner, H. J. Cates, H. S. Chale, T. A. Dawse, J. E. Eda, J. F. Gaskell, H. E. Gordon-Smith (Trin.), L. V. Hignett, W. Kirby, W. J. Lambert-Down, S. F. Linton, C. H. W. McCullagh, L. MacLachlan, Margaret S. Maclean, S. M. Naughton, Bona S. Matthews, J. H. Maund, J. Mitchell, B. R. Naidu, G. E. Oates, A. B. Olsen, A. W. Reid, J. R. Robertson, C. Rolleston, F. L. Stallard, S. Subba Rao.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

SECOND M.B., Ch.B. (Anatomy and Physiology).—H. el Arcelli, F. Dallimore, T. B. Evans, H. V. Elsie, C. Henson, H. W. Jones, R. Kennon, R. H. Knowles, T. H. Martin, H. Neill, A. L. Oluwole, W. H. Parry, H. Pierce, J. P. Rafter, H. G. Roberts, A. Seddon, S. N. Wright.

Materia Medica.—G. S. A. Bishop, F. G. F. Browne, D. H. Clarke, P. Le F. Nortie, T. O. Williams.

FINAL M.B., Ch.B. (Part A).—A. Adams, T. C. Clarke.

Part B.—J. A. Donnellan, A. A. Rees, S. P. Sykes, "S. V. Tinsley." * Second class honours.

The Diploma in Public Health has been conferred on C. S. Brewer, H. M. Cargin, Katharine R. Drinkwater, B. T. J. Glover, C. O. Stallybrass, J. Teare.

The Diploma in Tropical Medicine has been conferred on R. G. Abercrombie, J. R. P. Allin, H. P. W. Barrow, P. Carr-White, W. S. Clark, R. Cope, W. D. Hayward, W. P. Eldrum, J. C. Murphy, M. G. Samuel, M. H. Thornely, W. S. Webb.

THE ROYAL UNIVERSITY OF IRELAND.

THE following candidates have been approved at the examinations indicated:

M.D.—D. Gillespie, W. R. Hayden, R. Johnston, W. I. Leighton, A. Leitch, R. McCarrison, J. H. Stewart.

M.B., B.Ch., B.A.O. Upper Pass.—E. Forbes, P. Keelan, A. Kidd, J. M. O'Connor, B.A., T. Taylor, V. Wiley, J. M. Williams.

Pass.—"T. P. Carroll, J. A. Clarke, B.A., E. M. Condy, W. T. Henderson, W. F. Hooper, Caroline V. Love, S. W. McComb, J. P. Moore, Newman, P. H. O'Connell, J. J. O'Keefe, B.A., E. O'Reilly, R. H. Robinson, W. H. Sheffield, M. Shipsey, W. S. R. Steven, S. J. Watson, B. A. West.

* Qualified to sit for honours in one or more subjects of the examination.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved at the examinations indicated:

SURGERY.—"H. A. Hancock.

MEDICINE.—"B. A. Keats.

FORENSIC MEDICINE.—B. A. Keats, S. H. Scott.

MIDWIFERY.—L. Ettinger, J. A. Koch, R. Lamort, B. W. Loewenbergs, S. H. Scott, T. A. F. Tyrrell.

* Section I.

† Section II.

UNIVERSITY OF DUBLIN.

THE following were among the degrees conferred at a meeting of the Senate on April 22nd:

M.D.—G. B. M'Hutchison, G. S. Thacker.

M.B., Ch.B., B.A.O.—A. K. Cosgrave, D. Drew, R. D. FitzGerald, H. R. Kenny, A. H. Laird, W. D. Mitchell, G. H. L. McCarthy, G. B. M'Hutchison, D. M. Moffatt, H. H. Ormsby, E. H. Sheehan, A. J. Stals.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FIRST EXAMINATION.—S. Wright, C. A. Slaughter, J. H. Appoo, H. A. Topalia, J. Muller, W. Lessey, B. F. Limji, J. G. Lessey, H. G. Anderson, V. D. Nimbar, S. A. Anthoni, B. B. Galt, E. I. Parry, and W. Bird.

SECOND EXAMINATION.—R. H. Thomson, S. D. Large, A. E. MacKenzie, F. R. Lucas, J. R. Smith, A. Butterfield, O. W. Bateman, W. F. Gibb, T. R. C. Melrose, F. D. Johnson, K. Nath, V. T. W. Eagles, J. A. Frost, J. Ross, E. P. Ghose, H. Buksh, P. C. Banerjee, and W. W. W. Watt.

THIRD EXAMINATION.—J. Muller, C. G. Timms, R. M. McC. Wilson, B. G. Shirodkar, C. L. Jevors, R. Parry, J. K. Sharma.

FINAL EXAMINATION.—J. R. Le Touzel, C. L. Stewart, H. L. Batra, B. Nath, C. W. Gee, T. Mohan, H. W. Garcelon, W. R. Waddell, C. E. Watts, F. R. Watson, S. W. Hogg, J. McKelvey, H. H. Jackson, A. McMurray, A. E. Herat, W. Whitfield, B. G. Sherlock, J. McTurk, A. J. Brown, J. M. Mehta, J. M. Mody, T. C. Shand, R. H. Gray, E. N. Khory, M. L. Burke, T. M. George, J. E. Spencer.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examination indicated:

SECOND PROFESSIONAL.—J. C. Attridge, J. Barrett, W. R. Beeston, U. L. Bourke, F. C. Fisher, J. Good, A. F. C. Hogg, B. Malher, T. P. MacDermott, B. Murphy, L. J. O'Donovan, C. Petit, P. O'C. White, G. Wilson, G. Young.

Obituary.

THE LATE MR. SIMON SNELL.—From the list of persons representing the British Medical Association at the funeral of the late President the name of Mr. Smith Whitaker, Medical Secretary, was accidentally omitted.

THE International Milk Trade Congress will hold its fourth meeting, under the patronage of His Royal Highness the Grand Duke Joseph, at Buda-Pesth in June next (6th to 11th). The questions to be discussed are divided into three groups—legislative and administrative, hygienic and veterinary, and industrial. About 600 persons have already intimated their intention to take part in the congress, and some sixty communications are in the hands of the secretary.

Public Health

AND

POOR LAW MEDICAL SERVICES.

BACTERIOLOGICAL EXAMINATIONS IN THE PROPHYLAXIS OF DIPHTHERIA.

In an appendix to a reprint of a paper read before the Society of Medical Officers of Health dealing with the scientific control of diphtheria, Dr. W. G. Savage, of Colchester, gives an account of an inquiry made by him as to the extent to which scientific facilities established in aid of the control of diphtheria are commonly utilized. Having communicated with the medical officers of about 450 of the larger sanitary areas in England and Wales, he received 304 replies, and from an analysis of them he concludes that in most of these areas free bacteriological examination of smears is available. He found, however, diphtheria patients were bacteriologically examined before discharge from hospital in less than two-thirds of these districts, and only in 15 per cent. of the cases were three consecutive negative results deemed to be required. As for cases isolated at home, only in 25 per cent. of the districts were smears examined before the patients were released from quarantine. The neglect of bacteriological methods in respect of "contacts" he regards as still more striking. He found that only in 11 per cent. of the districts were "contacts" examined bacteriologically, and in 6 per cent. such examination was only partial. As for antitoxin, about half of the medical officers of health employed it prophylactically. The answers to his question regarding periods of detention were rather vague, but showed that where it was the practice to examine cases bacteriologically before discharge a considerable percentage of the cases were detained for three or four weeks longer than those discharged elsewhere on clinical evidence only. Many of the latter, therefore, must, he concludes, be sent out with living diphtheria bacilli in their throats.

SALARIES OF WORKHOUSE MEDICAL OFFICERS.

The Eastbourne Guardians have declined to accede to the application of Dr. James Adams for an increase of salary, but, while refusing his request, they have expressed high appreciation of his services. There are as many as 151 patients in the infirmary and 194 in the workhouse. At present the stipend is only £130. Drugs are supplied by the guardians, and are dispensed by the medical officer at a cost to himself of £20 per annum. The reasons given by the guardians for their decision are most unsatisfactory. One is that the salary is not smaller than those paid in other unions of the same size; and it was further stated that such posts were often held by medical men who were beginning practice and were prepared to accept very moderate remuneration.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Burton-on-Trent.—The population of Burton-on-Trent as estimated by the Registrar-General at the middle of 1908 was 53,936, but the Medical Officer of Health (Dr. J. M. Cowie), taking local conditions into consideration, estimated it at only 53,000. The birth-rate, calculated on the latter estimate, was 22.4 per 1,000, and the death-rate from all causes 12.9 per 1,000. The infantile mortality-rate was 112 per 1,000 births. Of the 133 children who died under 1 year old as many as 101 did not reach the age of 6 months. The illegitimate death-rate was equal to 243 per 1,000 illegitimate births. Dr. Cowie refers to the statistics given in the supplement to the sixty-fifth annual report of the Registrar-General, in which brewing as a trade is shown in a very favourable light from a health point of view. From figures which he has taken out covering a period of eight years with reference to the mortality amongst brewers and years of age engaged in the brewing trade in Burton, he shows that, although there is a greater mortality amongst brewers than among all males in the borough, the excess is not nearly so great as it is found to be in the whole country. From diseases of the circulatory system and of the respiratory system the Burton brewers suffer in a less degree than other men in the town.

Borough of Guildford.—Calculated on a population of 22,800, the birth-rate was 25.6 per 1,000 and the death-rate 11.0 per 1,000. The infantile mortality-rate was equal to 73 per 1,000 births. The deaths among young children were at one time unduly high in Guildford, but during the past five years they have been remarkably low. It would be of interest to know whether this decreased mortality is real or only apparent—that is to say, whether it is in any way connected with the enlargement of the area of the borough which took place in 1904. It is not possible from the report to ascertain whether any special parts of the town have a higher rate of infantile mortality than others, for Dr. Pierce does not include Table II of the Local Government Board among his statistical records. Some trouble has been experienced at the Guildford, Godalming, and Woking Joint Hospital with respect to return cases of scarlet fever. The following notice is therefore now given to patients on their discharge: "Although every care is exercised to ensure that

patients are free from infection before leaving the hospital it is impossible to guarantee this. Whenever practicable, the child should be sent to a house where there are no children, but when this cannot be done care should be taken for at least three weeks that the child does not kiss or come into close contact with any one, and it should on no account be allowed to sleep with others, especially in the same bed. The child should be taken into the fresh air as much as possible, but must not be sent to school or into any other assembly of children. It is also recommended that during this period the articles used by the child (such as handkerchiefs, towels, toys, cup, plate, spoon, etc.) should be kept distinct from those used by others."

Borough of Neath.—The annual report of the Medical Officer of Health on the vital statistics and sanitary condition of the Borough of Neath records 556 births and 288 deaths, including 17 non-residents. The birth-rate was 33, whilst the death-rate was 16 of the estimated population. The general health of the town was good, the weather conditions, excepting during the first two months, being favourable. The deaths from the principal zymotic diseases numbered 35, giving a zymotic death-rate of 2 per 1,000 of the population. The number of deaths of infants under 1 year of age was 75, equivalent to an infantile mortality-rate of 131, as compared with 121 for the whole country. The figure is considerably less than that for 1907, when Neath stood in the unenviable position of being at the head of the list for the county. The medical officer states: "At the same time, the figure for 1908 is not one that can be made cause for congratulation. There are far too many children brought into the world in modern times whose sole mission seems to be to suffer needlessly. The occurrence of 5 deaths recently within a fortnight of infants under three weeks old from the disease known as 'white mouth,' from which no healthy infant—there are extremely few infants unhealthy at birth—ought to suffer, but which practically every child of the working or poorer classes has to suffer from, is only an incident in what is nothing less than a scandal. I have frequently pointed out that whilst the untrained midwife, with her habits and superstitions, is allowed to foist herself on the community the present condition of things must endure. In this connection I think that it is more than 'worse than strange' that the women of notoriously drunken habits—and we have several of them in Neath—should be allowed to practise this profession. The law seems sufficiently explicit on the point, and I have more than once complained of it, with its tragic consequences to mother and infant, to the proper authority, but my complaints have hitherto had no effect. I am about to address a circular to the midwives, calling their attention to the means of prevention of 'white mouth,' and have secured the help of the National Society for the Prevention of Cruelty to Children, who promise to institute proceedings in case of neglect on the midwife's part." With regard to meat and food inspection, it is stated that the slaughterhouse was visited several times weekly by the inspector. The carcasses of eight animals were seized and destroyed, by order of a justice, for tuberculosis. In one case the slaughterman tried to "strip" the pleura, for the purpose of removing traces of the disease. Such attempts at concealment might be made ground for prosecution. There was one prosecution against a fishmonger for being in possession of a quantity of decomposed fish, and also one prosecution in regard of milk below the standard; both were successful. In regard to meat inspection, the medical officer of health recommends that power should be given to the local authority to prevent the bringing in of meat from outside the borough, sometimes from the boundary line, as to which there is no guarantee that it has been inspected. A localized outbreak of diarrhoea in October was traced to eating brawn made by a butcher, but by what means the brawn became infected it was impossible to say.

Croydon Rural District.—Some idea of the rapid growth of the Croydon Rural District may be gathered from the statement that in 1900 the number of occupied houses was 6,597, whereas in 1908 it was 11,362. There are within the district the Cane Hill Asylum and the Holborn Workhouse and Schools, and, omitting the inmates of these institutions, the estimated population in the middle of last year was 57,600. The birth-rate was 25.1, the death-rate 10.1 per 1,000, and the infantile mortality-rate was 84 per 1,000 births. The District Council places at the disposal of all medical practitioners the means of having the diagnosis of cases of infectious disease confirmed or otherwise, and also at the end of the illness for determining whether the patient is free from infection. With regard to diphtheria, it is the custom to consider each case infective until a bacteriological examination shows the throat to be free from the Klebs-Loeffler bacillus. Measles has been notifiable in the Croydon Rural District since 1890, and in 1908 there were 1,929 cases and 31 deaths occurred. Dr. Fegen (the Medical Officer of Health) has to confess that, in spite of all endeavours, no very successful means of checking an epidemic of measles has been discovered, for all prophylactic precautions have to a very large extent proved abortive. The main factors in the spread of the disease are, in his opinion, personal intercourse, school attendance, and the gathering together of children at entertainments.

The Southern District Medical Society of Chicago has, according to the *Medical Record*, recommended to the General Assembly of Illinois the enactment of "a law requiring the sterilization of habitual male criminals, imbeciles, incurably insane, and epileptic persons" in the State institutions of Illinois.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.

The offices of the British Medical Association and of the British Medical Journal are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *429 Strand, London*; the telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National).—

2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2630, Gerrard, BRITISH MEDICAL ASSOCIATION.

2634, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring republication of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

15. We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "Enquirer," and so on. By attention to this request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

CLIFTONIA asks for information as to the value of the formic acid treatment for rheumatism and as to its mode of administration.

"14" asks for advice in the treatment of one-sided subluxation of the jaw in a young lady; it occurs only during sleep and to prevent it she has to tie a bandage tightly round the head.

D. E. asks for information as to the most suitable resort in England or Wales to stay at during May and June for a sufferer from bronchial asthma.

FIBROLYSIN IN MIDDLE-EAR DEAFNESS.

SOUTH AFRICA asks for information as to an instrument for massaging the drum in cases of tinnitus and middle-ear deafness, to be used in connexion with hypodermic injections of fibrolysin, and as to whether the treatment is fairly successful.

*. Whilest the treatment of tinnitus and middle-ear deafness by means of hypodermic injections of fibrolysin has been advocated by some, it has been tried and abandoned by others. This form of treatment must therefore for the present be regarded as *sub judice*, if not as still in the experimental stage. It is therefore difficult to answer categorically in the negative or in the affirmative the second question.

For information generally on the subject, our correspondent is referred to Professor A. Lucæ's monograph, *Die chronische progressive Schwerhörigkeit: Ihre Erkenntnis und Behandlung*, pp. 316, 317, 318, published by Julius Springer, Berlin. The two following papers might also be consulted: Martin Sugar in Budapest, Ueber Thiosinaminbehandlung des chronischen Mittelohrkatarrhs. *Archiv für Ohrenheilkunde*, Bd. Lxii, S. 241. L. Hirschland, Ueber die Verwendung des Thiosinamins und "Fibrolysin" in der Otologie und Rhinologie. *Archiv für Ohrenheilkunde*, Lxiv, S. 107.

ANSWERS.

TREATMENT OF SYPHILIS.

ANXIOUS.—The ulcers noted in the lower part of the leg upwards of a year ago should probably be taken as evidence that the case of syphilis in question was then in an early tertiary stage. It is commonly held that once a diagnosis of syphilis has been established treatment of the case by mercury should extend to at least two years, even if no further symptoms of syphilis are observed; and it has frequently been maintained that no case can be regarded as cured until two years after the disappearance of the last

observed symptom. It is neither necessary nor desirable, however, to continue mercurial treatment uninterruptedly. The extent to which mercury is pressed must depend on the course of the individual case; but, whatever that may be, its administration should be planned on a definite system of rest, during which mercury should be withheld. As this particular case has hitherto done well on grey powder, a guide to further treatment may be afforded by the following table, which is copied from *The System of Syphilis* (by D'Arcy Power and J. Keogh Murphy. Oxford Medical Publications, 1908). It is there mentioned as the routine method of giving grey powder in the British army, in which treatment of syphilis by grey powder at one time reigned supreme. The pills in question each contain 1 grain:

	Months.	Pills.
First Course:		
One month taking six pills a day	1	180
Interval of three days without taking pills	—	—
One month taking four pills a day	1	120
Interval of seven days	—	—
One month taking three pills a day	1	90
Interval of one month	1	—
Second Course:		
Three months taking three pills a day	3	270
Interval of one month	1	—
Third Course:		
Three months taking two pills a day	3	180
Interval of one month	1	—
Fourth Course:		
Three months taking one pill daily	3	90
Interval of three months	3	—
Fifth Course:		
Three months taking one pill daily	3	90
	21	1,020

Aix-la-Chapelle is the spa best known for the treatment of syphilis. The course lasts three or four weeks or more, and consists in medical baths and hydropathic treatment. Its cost mainly depends on the hotel or boarding place chosen. A sum of six or eight shillings could probably be made to cover the cost of rooms and board. If, however, the patient has been free from all evidence of syphilis for upwards of a year, and is apparently in good health, there would not seem to be any advantage in sending him to any special health resort. Continuation of the present treatment for an adequate time should suffice to cure him, so far as syphilis can ever be regarded as absolutely eradicated from the system.

LETTERS, NOTES, ETC.

THE TREATMENT OF MORPHINOMANIA.

DR. S. RAMASWAMI AIYAS (Kottayam, Travancore) records the following case of morphinomania. The patient, a man aged 38, a B.A. of an Indian university and holder of a Government appointment, acquired the morphine habit two years ago as a result of a hypodermic injection given for an attack of dyspepsia; and was taking as many as eight injections a day, each containing injectio morphinae hypodermica 20 minims, and also gin to counteract occasional suppression of urine. He came under medical observation owing to the operation of a recently instituted law which made it difficult for him to obtain morphine himself. His symptoms were apathy, extreme restlessness, sleeplessness, aching pains throughout the body, and occasional clonic spasms of the muscles of the trunk and face. His appetite was poor, but, curiously enough, there was neither diarrhoea nor constipation. The patient, having agreed to attempt to abandon the habit, was first given 1-grain doses of opium by the mouth, with small doses of atropine, but as no effect on the craving was noted this treatment was dropped after a few days. To procure sleep a large dose of bromide was given on the first night, but as it did not act a 3-minim injection of morphine was given the next and following seven nights, sleep resulting in spite of the smallness of the dose. The next two nights hyosine hydrobromide was substituted, but, proving useless, morphine was again given for three nights and was then dropped altogether. Meantime the patient had been taking during the day cold shower baths followed by massage and gentle exercise. By the end of a fortnight all craving had passed away and it is not considered likely to return. Morphinomania, it appears, is rare in Travancore, though opium eating is common.

GASTROSCHISIS.

DR. A. R. JOHNSTON (Porfir, N.D.) writes to say that in February he delivered a primipara, aged 36, of a full-term male child, perfectly formed except as regards the abdominal wall. This was defective in the epigastric, umbilical, and right and left iliac and hypogastric regions, and totally lacking in the right and left lumbar regions, with the result that the whole of the upper surface of the liver and part of the intestines and other viscera were exposed to view. The intestines and other viscera were of normal length, spread out in the umbilical cord, which was of normal length, spread out in the fan-shaped fashion at its fetal end, and blended in the upper part of the gap with the capsule of the liver, and below with the mesenteric and visceral peritoneum. Similarly the skin of the abdominal wall blended at the upper

level with the thickened capsule of the liver (that is, the true capsule plus the amniotic covering derived from the umbilical cord) and in the lower part with the peritoneal covering of the viscera. The child lived twenty-nine hours, having meantime taken a few teaspoonfuls of sugar and water, and passed urine and meconium. It did not vomit, but occasionally some bloodstained froth appeared at the corners of its mouth. Before death the stomach became distended with gas, and thus brought the spleen into view, and the intestines grew red and congested. The liver was dark and exuded some blood, probably owing to breaches of surfaces being caused by the dressing applied sticking to it. The mother during the second month of pregnancy had a fright followed by a certain amount of dark-red vaginal discharge, and all through her pregnancy expected that the child when born would not prove healthy.

METHODS OF QUACKERY.

DR. JAMES W. KIDD, of Fort Wayne, Indiana, U.S.A., whose methods were explained in the *BRITISH MEDICAL JOURNAL* of March 13th, 1909, p. 671, is now offering to give to every person in the British Empire who has previously applied to him for treatment a complete course of treatment for ten shillings. This, he says, is not reasonable payment for the time he has spent on the case; and adds, "but I want a cured patient in your community. I must have a cured patient in every town and hamlet in your country. I have found by experience that I can afford to sacrifice all my profits to secure a cured patient in each community." He has, he adds, selected the case of a few people in each community whom he knows he can cure. The recipient is assured that it is "the chance of a lifetime to be restored to perfect health." The treatment consists of a series of tablets, and the result of their analysis will be found in the *JOURNAL* of March 13th, 1909, p. 671. The chief ingredients of these tablets appeared to be sodium carbonate, gentian, sodium benzoates, oil of winter green, and aloes.

DESTRUCTION OF SWEAT GLANDS BY THE ROENTGEN RAYS.

DR. H. G. ADAMSON (London) writes: In the *BRITISH MEDICAL JOURNAL* of April 17th, p. 955, Dr. Howard Price, in recommending x-ray applications for the treatment of hyperidrosis, states that his attention was first called to the action of the rays on the sweat glands four years ago. This treatment has, however, been used for a still longer period. Puzey in America is credited with having first employed x-rays in the treatment of localized hyperidrosis. He published a successful case in 1903 (*Journal of Cutaneous Diseases*, August, 1903, p. 355). Kingman, also in 1905, reported a case of axillary hyperidrosis (*Interstate Medical Journal*, July, 1905, p. 375). In 1904 Müller recorded a case of hyperidrosis of the hands cured by x-ray applications, and one of perianal hyperidrosis much benefited (*Munch. med. Woch.*, June 7th, 1904, p. 999). Glover in 1905 published a case of hyperidrosis of the axilla cured by this method (*Rev. Internat. d'Electrotherap. et Radiotherap.*, Nos. 10 and 11, April and May, 1905). Many other writers have recorded cases since then, and x-ray applications have now become a routine treatment for local sweating, while the method recommended by Mr. Price of maximum doses (4 Holzknecht units, or just short of a Sabouraud pastille dose) at intervals of one month is the recognized manner of employing them.

AURAL AND OTHER VERTIGO.

DR. W. G. WALFORD, of Finchley Road, N., in a letter relative to the article by Mr. W. S. Syme published on April 10th, informs us that last year ago he suffered from severe vertigo. After four months he suddenly discovered that it was due to wearing tight neck clothing, and on ceasing to do so recovered so rapidly that in a fortnight he was able to resume bicycling, although over 70 years of age. His general health also began to improve, and now after eight months he has regained his hearing, which before was defective. He does not consider his case one of pure aural vertigo, but of vertigo due to general cerebral congestion. He had a hard, full pulse, ecchymoses in the vitreous humours, and enlarged and congested ocular vessels. Cerebral congestion brought about by tight neck clothing lies, he believes, at the bottom of many cases of vertigo. Although no longer in practice, he has seen cases which have supported this theory, one being a boy who, sick, dazed, and complaining of toothache, had his pupils greatly dilated and unresponsive to light. All the symptoms passed off as soon as loose neck clothing was substituted for that which he was wearing. In former days, when chokers were worn in the army, apoplexy and sunstroke prevailed among soldiers to a very much greater extent than in the navy, the neck attire of sailors always being loose. Apart, however, from morbid conditions more or less obviously caused by defects in the circulation, he has found reason to believe that ill-health and cachexia of a general kind may be engendered by wearing from childhood upwards clothing which restricts communication between the heart and brain. In his own case it was not only the cerebral symptoms that passed away, but general health improved enormously, and similar improvement took place in two of his relatives—one a man past middle life, the other a young man of 26—when attention was directed to their neck clothing. This was not tight, according to ordinary rules; but, nevertheless, its further loosening was followed by great and rapid benefit to their physical condition. Furthermore,

all three of them found that their necks grew in circumference. In Dr. Walford's own case this growth was very marked, for it reached as much as 2 in.

THE PUPILAGE SYSTEM.

DR. THOMAS LAFFAN (Cashel) writes: The late Mr. Wheelhouse brought frequently before the medical public the immense advantages which would be derived from reintroducing the apprenticeship system into the training of medical students. He published an excellent pamphlet on the subject, which should be read by everybody. Of course, he did not propose to bring back the old system in its entirety. Nobody now suggests a return to such a waste of years. He did, however, propose that every young man should enjoy the advantage of that practical training which apprenticeship to a practitioner alone can give. The great enemies of this proposal are the schools and licensing bodies, though they well know that nine out of every ten of those who are now turned out receive no practical training whatever, except the veneering necessary to pass the examinations. English general practitioners so often expose in the columns of the medical papers the mere theoretical attainments of many of their assistants that further labouring of this cause is unnecessary. The young idea supplies want of practical knowledge by a superabundance of conceit. The Irish College of Surgeons have a unique opportunity now for saving their situation by doing that which they so blindly refused to do a few years ago.

A PRIESTLY FEBRIFUGE.

CAPTAIN HODGKINSON LACK, I.M.S. (Dr. Dufferin, Mandalay), writes: In your issue of February 13th, p. 444, there is a note by Dr. A. P. Lange on the subject of a herbal febrifuge used by him in Conva in the island of Trinidad, B.W.I. I think that I know the herb of which Dr. Lange writes, and I also know of one or two other shrubs used for medicinal purposes out in Trinidad. For example, the leaves of a certain shrub—known locally as "Cousin Maho"—are used, as a decoction, in cases of cardiac disease in which strophanthus would be the recognized indication. I remember its being used in the case of a member of my own family who appeared to be benefited after the known cardiac muscle tonics had apparently failed. Secondly, I am informed that, when I was about two years old, I had a severe attack of dysentery and was "given up" by the medical men in attendance—whereupon an old servant of my mother's took me in hand and gave me small doses of a decoction of the leaves of a shrub known locally as the "Bird Pepper." This appeared to produce the desired effect. Thirdly, there is a kind of weed known locally as the "English Plainain," which appears to be of some use as a collyrium. The broad leaf is placed over a tumbler, and a fairly hot flat-iron is placed on it; the leaf shrivels and at the same time exudes a few drops of clear liquid which are collected in the tumbler. Again, in my own case, after the failure of various medicaments to effect improvement in what I now recognize to have been granular conjunctivitis, this liquid was used and gave great relief and ended up by curing me of a rather troublesome ailment. Fourthly, it is, I think, fairly well known in Trinidad that cases of seborrhoea capitis (dry) will often yield to the application of the slimy exudate obtained on splitting the thick young stems of the wild aloe, when recognized therapeutic agents fail to do any good. Fifthly—the list would not be complete without such a one—there is a kind of weed (whose local name I have now forgotten) a decoction of which has a reputation as a sedative in cases of cholera. I have no personal experience of this! Might it not be of some use if members of the Association sent samples of such medicinal agents? If arrangements could be made to investigate such substances some valuable information might be obtained. Out here in India and Burmah, many such instances come to the notice of medical men.

PRIMITIVE POLITIZATION.

DR. E. M. SMITHS (Goombunge, Queensland) writes: While talking to an old settler here a few days ago I heard of a primitive method of politization. One of the old man's sons had become very deaf through diving in a water-hole. One day he found the deaf son laid on his back, while another son held his nose and mouth closed, and a companion thrust his whole weight on the deaf boy's abdomen. The deafness was cured by one application.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0 0 0
Each additional line	0 0 6
A whole column	2 13 4
A page	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

A Lecture ON MYOPATHY AND SYRINGOMYELIA.

DELIVERED AT THE NATIONAL HOSPITAL FOR THE
PARALYSED AND EPILEPTIC.

By SIR W. R. GOWERS, M.D., F.R.S.,
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—You may wonder why I have linked together two diseases so diverse in nature as the subject of this lecture. It is because they were connected by a link, the effectiveness of which you will at once admit, and also its

actual utility—the link of error. I will show you a case which is certainly one of syringomyelia, and was thought at first to be also the subject of muscular dystrophy. If you study your errors properly and do not yield to the natural temptation to push them hastily out of sight with your foot, you may learn much from them. But you will probably find it easier to give special attention to errors in diagnosis that are not your own.

You will not learn quite so much from them, but the habit, once acquired, will not be easily discarded. That which concerns one's self is naturally fixed more firmly in the mind and the memory.

You know that syringomyelia is a malady that presents many of the features which are produced by various diseases of the spinal cord. But of these two are the more common—loss of sensation of pain and often to temperature without loss to touch; and, secondly, muscular wasting. The case I will show you presents both these symptoms. The sensory loss is a symptom which has to be sought for. This patient was ignorant of its existence. It is very easy for any person to be unaware of that which is only shown by the absence of discomfort. These cases illustrate the fact that pain is a precious danger signal, by the injuries its loss permits. The muscular wasting is that which brought the patient into the hospital, and it happens to present peculiar characters which bear a resemblance to those presented by a man with true myopathy now in the ward, whom I will show you first.

The two maladies ought not to be confused, although they are both diseases of development. The one is defective structural formation in the spinal cord, whereby cavities are left in the process of its development or portions of embryonic neuroglial tissue fail to achieve their change into nerve elements, but remain as tracts of low consistence, which break down into cavities. These enlarge by distension and thus cause symptoms, or the residual tissue may increase by a slow process of growth. Myopathy, or muscular dystrophy, is a defect of muscular growth, not dependent on the nervous system, but inherent in the muscles, by which the fibres fail, sometimes early in life, sometimes later. The interstitial tissue grasps the nutritional influence and increases, but not enough to compensate for the defect in the fibres, unless fat forms among

them, when the bulk of the feeble muscles may be much increased. This is the case in the early variety, the pseudo-hypertrophic form, which you probably know best; in this the muscles vary in size, the calves being usually largest, the extensors of the knees often increase in size in the lower part, the infraspinati are large, the lower parts of the pectoralis and the latissimus dorsi are small, and often they seem almost absent. The face is free. This form affects chiefly males, females seldom; sometimes all the males of a family suffer, and all the females escape, but transmit the disease to their sons. The malady increases in degree and extent as its subjects grow up; it impairs the power of breathing until some pulmonary disease develops; or it may be some slight catarrh, which would be a trifle to a normal individual, ends the feeble life soon after adult age has been attained.

But there are other forms of myopathy which do not present the increased size of muscles. On the contrary, all or most lessen in size, though often not to the same degree as in spinal atrophy. A more abundant growth of the interstitial tissue takes place, but it does not become the seat of fat formation, partly perhaps because the change usually takes place after the period of growth is over. One of these forms, which is

Fig. 1.—T. R., man with facio-scapular myopathy, showing abnormal elevation of the scapulae.

Fig. 2.—The same, from behind.

particularly well marked, is termed the "facio-scapular" form, from the groups of muscles which are constantly involved. It is also called after Landouzy and Dejerine, its first describers. It is to this form that the case belongs which I am now going to show you (Figs. 1, 2, and 3). The malady sometimes begins in early life, but more frequently not until growth is nearly over, and it may go on increasing and becoming distinct in fresh parts even for thirty years. If you observe the face and test the closure of the eyelids by opposing it, the least force is sufficient to keep them apart. In a moment I will point out other indications of this form. This man is 44 years old. His son is here,

who is likewise suffering, for this form of myopathy develops so much later than the pseudo-hypertrophic variety, that the subjects survive to an age at which they can transmit the disease. In the pseudo-hypertrophy, life usually terminates too soon for this, and the ability to pass it on to another generation is unknown. This facio-scapular form is eminently transmissible, as is shown by the family history of this patient. Of ten children in his family he is the only survivor. Three died in very early life, and of the six others all

are known to have suffered—two females who died at 19 and 26, and four males who lived only to 21, 22, 35, and 37. Their mother also suffered, and from her they received it, and so did her own mother. On his father's side there is no indication of the malady.

In the neck the sterno-mastoids are small, but act well. The upper part of the trapezius, which extends between the occipital bone and the shoulder, seems gone on each side; the rest of these muscles is small but present. You know that this upper part is usually the last to be affected in spinal atrophy, the *ultimum moriens* Duchenne called it; but it suffers often alone in myopathy. The deltoids are good; the triceps small and weak, and each biceps is changed in shape, small in the upper and lower parts, but

Fig. 3.—The same, showing contraction of the biceps.

full in the middle, standing out as a lump when put into firm contraction (Fig. 3). The forearm and hand muscles seem normal. The pectorals are irregularly affected; only small parts remain of the lower half. The serrati are gone, and the angles of the scapulae project, from the tilt of the bones; the erector spinae is small. The supraspinatus seems normal, and has not the prominence of the infraspinatus. This appears to be distinctly enlarged, and like most other muscles is the same on each side.

Wasting in the abdomen seems chiefly in the lower part of the oblique muscles on each side. The rectus is strong, but when he attempts to sit up the abdominal wall on each side bulges out, as you see, in a remarkable shape. In the legs, the muscles are generally small, but none are much affected except the anterior tibials and extensors of the toes, which are much wasted and have little power, so that in each leg there is foot-drop; but the peronei are good. The knee-jerks and ankle-jerks are present. He can stand on either leg and walk, but tends to catch his toes against any elevation. Sensation is everywhere normal.

It is not easy to learn the history of his symptoms, although he is not an unintelligent man. The impairment

in the arms became worse about seven years ago, and his walking has suffered more recently. But he has been able to work at his trade until just now; it consisted in stuffing the cases of mattresses with hay, an occupation we should not think laborious, although he avers that it is very tiring, and doubtless it is to him. For seven or nine years he has been conscious of weakness and pain in the left shoulder and upper arm, and later of pain in the lumbar region. Attacks of influenza, twice with pneumonia, have seemed to add to his loss of power. The weakness in the feet has been conspicuous during the last year or two. The pains led to a former diagnosis of neuritis, but were probably caused by the strain on the fibrous tissues which the muscles usually support in part. It is probable that the gradual muscular failure dates from early adult life, but for long it was unnoticed,

forward. The pectorales are not markedly atrophied, but they seem weak. On the other hand, the infraspinati are abnormally large, as they are commonly in the pseudo-hypertrophic form. There is no distinct wasting of the leg muscles, but the strength of the flexors of the ankle is small. All reflex action, superficial and deep, is of normal type.

I now show you the other case, a woman who has certainly syringomyelia and was at first thought to be the subject of myopathy; but more careful observation only justifies the first. She is 31 years of age and married early, having two healthy children. Nothing can be learnt that suggests any family malady, tubercle or myopathy, and she has never had any indication of syphilis; yet her past history presents one peculiar feature, which is of considerable importance in reference to our present question. In early life she possessed unusual muscular power, such as is rare in women. She was fond of its exercise, especially in swimming and gymnastics. When about 16 she gave public exhibitions in each of these. She could walk thirty miles without fatigue, until her strength failed, five years ago. Her performances necessarily entailed constant practice, and the muscular exertion, long continued, led to widespread hypertrophy of the

Fig. 4.—The son, with facio-scapular muscular myopathy.

because the muscles that were affected could be supplemented by others, at any rate to a large extent. Moreover, the parts that are not wasted are rather large, and are perhaps the seat of some true hypertrophy. The weakness of the face was unknown to the patient until he came here. It involves no conscious disability.

The great variations in the age at which this facio-scapular form begins and also the rapidity of its progress are sufficiently shown by the ages at which the affected brothers and sisters died, which I have mentioned. Other recorded cases illustrate the same fact, and in most of the families some of those who suffer have married and transmitted the disease, and this has happened, as in the family before you, with both sexes.

Our patient has a daughter and a son, but the daughter is only 11, and is said to present no sign of the disease. The sister who died at 26 was married, and left a daughter, but her state is not known. I show you our patient's son (Fig. 4). The orbicularis palpebrarum are conspicuously weak; they cannot overcome the gentlest hindrance to the closure of the eyes. The orbicularis oris is also feeble. The sterno mastoids are good. The trapezii are greatly wasted. You can even see the projection of the cervico-dorsal spines. The serrati also have little power; the scapulae project when the hands are put

Fig. 5.—Anesthesia—vertical lines, broken where incomplete. Thermo-aesthesia—oblique lines.

muscles, traces of which are still obvious, especially in the arms and calves.

That she is the subject of syringomyelia is evident from the extensive loss of cutaneous sensibility to pain, without loss, or with very limited and partial defect, of sensibility to touch. I show you the distribution of the loss to pain in this diagram (Fig. 5). Its degree is indicated by continuous lines where it is complete, and by broken lines where it is imperfect in degree. It is partial over the right shoulder and the upper half of the arm and on the right front of the thorax: on the middle of the abdomen it is complete, in an area narrow at the ensiform cartilage, broader below, ceasing above the pubes, where it is interrupted by a zone of normal sensibility, but it is renewed again by complete analgesia at the top of each thigh. It becomes partial at the middle of the thigh, and ceases a little above the knees. This loss passes to the back of the hips and outer part of the thighs, and it extends incompletely across the gluteal region, except in the distribution of the lowest sacral fibres, where sensibility is normal on each side of the anus. It passes, in a pyramidal form, up the lower half of the back. Temperature-sense is impaired only in the small regions marked by oblique lines; touch only in slight degree on the right thigh, marked by transverse lines. You will find those directions of lines generally advantageous for depicting the loss of the different forms of sensation—perpendicular for pain, transverse for touch,

oblique for temperature. It is distinctly convenient always to use the same system.

If you compare this diagram with one for the cutaneous distribution of the spinal segments, as shown by that of the nerve roots (which I may assume you know), you will see that there is very little correspondence. The chief correspondence is in the escape of the lowest sacral in the region on each side of the anus (these cavities usually cease at the lower extremity of the cord). Elsewhere little correspondence can be traced. The analgesia only occupies parts of the thoracic and lumbar segments. Yet the region affected is not irregular. Over the back it extends through a diminishing medial area, pyramidal in form, which ends upwards to a point about the ninth dorsal spine. In front a corresponding area is involved, which is continuous with the loss on the right side of the thorax. The loss on the abdomen is interrupted by the zone of normal sensibility, in the position of the twelfth dorsal segment, but larger, and the loss begins again in the higher part of the thigh in each leg and continues, to cease above the knee. Except on the thorax, there is considerable bilateral symmetry in the loss, although there is seldom correspondence with the spinal segments.

The explanation is that the cavities which chiefly interrupt the sensibility to pain are usually situated in front of the posterior horn, in the middle of the half-cord, and probably damage the path for pain, which seems to cross in the posterior commissure. They are often roughly symmetrical. The impressions conducted by the nerve roots seem to be soon rearranged in the cord for their upward conduction, and their interruption has thus an effect different in distribution from that produced by interruption of the nerve roots themselves. It differs also in nature, because touch escapes. Sometimes, however, a cavity occupies the posterior cornu, and may be so situated as to interrupt the root nerves after they have entered the cord. Then all forms of sensibility may be impaired, and the loss may correspond in distribution with one or more of the spinal segments. But the variations in the position of the cavities is so great that no generalization from the loss of sensation to the position of its cause seems yet to be possible.

Next to analgesia, muscular atrophy is the most common effect of syringomyelia. The cavities often occupy the region behind the anterior cornu, as I have just said. Their gradual enlargement may cause an invasion of the anterior horn with destruction of the nerve cells; the related anterior nerve fibres then slowly perish, and the muscles to which they are related. Thus a slow progressive muscular atrophy occurs very frequently in some parts, but the effect is not always slow. A cavity may increase rapidly; the erosion of the wall may expose an artery to influences which induce thrombosis, and sudden necrotic softening in the vicinity, or rupture. Then there is quick, even sudden, loss of power and acute degenerative changes in the electric irritability of the related muscles.

A sudden process evidently must have occurred in a cavity on the right side of the cord in this woman. She was not aware of any impairment of motor energy until it came, suddenly and gravely, five years ago. She was walking out with her child, and she fell, without cause. She could not rise again, but when helped up she did not fall, but managed, with care, to walk a short distance home. It is not easy to ascertain what had happened, but she could never again flex the right hip. The power of flexing the left hip is said to have failed slowly during the next year. Probably wasting came on at the same time in the higher part of the muscles in front of the thigh. Now both are weak and similar. The lower halves of the extensors of the knee are large and strong. When they are contracted they present a striking contrast to the upper parts, projecting just as does the middle part of the biceps in the man we first examined.

The extended legs cannot be raised from the couch on which she lies. We cannot see the flexors of the hips, the psoas and iliacus, or we should doubtless find them much wasted. I think that it is the condition of the thigh muscles, the extensors of the knees, with wasting in the upper parts and not in the lower, together with the large size of the calves, which suggested the presence of muscular dystrophy.

But another symptom seemed to confirm the opinion. If she sits on the floor, or kneels, she is unable to rise with-

out help. In the attempt she makes to get up, to achieve the upright posture, she adopts the same expedient that is so constantly seen in pseudo-hypertrophic paralysis, and hardly ever in any other condition. She puts her hands on the knees or on the lowest parts of the thighs. This is to aid the extension of the knees. The weight of the trunk rests on the hip-joints, at the upper end of the lever formed by the femur. The fulcrum is at the knee and the power, the extensor muscles, acts on the femur, between the weight and the fulcrum, the position of least advantage. By the transfer of much of the weight, by the hand, to a position near the fulcrum, the power is beyond it, and then acts to much greater advantage. The greater ease with which then the knees are extended, and the weight of the body raised, is the reason for the adoption of this device in pseudo-hypertrophic dystrophy. Some patients supplement this also by making the hand climb up the thigh and so aid the extension of the hip, but the patient has not enough defective power in the extensors of the hip to need this. I have often wondered that patients with other forms of loss of power in the extensors of the knee do not adopt the device. Probably it is only discovered by reason of the gradual onset of the extensor weakness in the muscular disease during the period of growth, when the expedient comes, as it were, naturally to the versatile muscles of the growing child. I have often looked for it in other cases, but I think I have never seen it until this case. It obviously seemed to support the idea that she was also the subject of muscular dystrophy, but it is not a symptom, as you see, on which any absolute weight can be placed.

You can now better understand why we decide that she is not suffering from muscular dystrophy, and yet we can perceive that the mistake was easy. The two diseases are not mutually exclusive, nor have they any mutual predisposition. If they occur together it would be simply as the consequence of what, in our ignorance, we call chance. Indeed, syringomyelia has been found, I believe, to co-exist with myopathy in 1 case out of more than 300 cases of the spinal affection which have been published, but the facts I have mentioned show how carefully such cases must be scrutinized, since in both diseases the muscles suffer.

In this woman the facts I have mentioned leave no doubt that syringomyelia exists, and also that a sudden lesion must have occurred in a cavity on the right side, extending its forward erosion into the anterior cornu, probably by thrombotic softening, with destruction of nerve cells, paralyzing the flexors of the right hip and the upper part of the extensors of the knee. The corresponding grey matter on the left side of the cord, according to the patient's account, did not then undergo damage, but this followed, in the course of the next year, by a process of more gradual character. Where the destructive process by which the nerve cells perished was rapid or sudden, so far as a group of cells is concerned, the electrical condition in the muscle supplied would be the "reaction of degeneration." You remember what this is; faradic excitability, which depends only on the nerve fibres in the muscle, fails rapidly, but the muscular tissue responds in increased degree to the slowly-interrupted voltaic current, and the kathodal closure contraction ceases to be the first, and is replaced by the anodal or positive. The time which has elapsed since the destruction, and the fact that this is not complete, prevents any evidence from the faradic response. The normal fibres that remain are sufficient to give a contraction to this. But on carefully examining the muscle in the upper part of the thigh with the voltaic poles, we find that the first contraction, on slowly increasing the strength of the current, is at the anode, not at the kathode. This shows that in the muscle are many fibres of which the nerves have undergone degeneration, although the fibres of the muscle have not wholly perished, and they still present this feature. It shows that there has been an acute process in the nerve centre. It is a feature never found in myopathy, and compels us to ascribe the state of the muscles to that of the spinal cord.

Thus it is clear that the condition of the muscles in this patient is not the same as in the man whom we first examined. Although they are similar in partial enlargement, the variation has not the same nature or the same distribution. The smaller part presents indications that it

depends on the state of the spinal cord, disease of which is proved by the presence of the change in sensibility of the skin, of which the patient was unaware, and which corresponds in greatest intensity to the region in which the lesion must lie which causes the wasting of the muscles. The remarkable size of those that are not wasted is explained by the patient's history in the rather distant past. At the time when the growth of all structures is most active her muscular system underwent a long course of systematic exercise, very unusual in degree, of which the remains are still distinct.

It seems strange that a girl with this congenital defect in the spinal cord should have been disposed to undertake such remarkable feats of muscular power without any family inducement to cultivate agility and energy. But her defect in the spinal cord is always chiefly in the posterior and medial parts, in the sensory regions of the cord. The change in the motor region is the result of a later extension, and it rarely occurs in early life. We may, perhaps, conceive that the motor processes, which so dimly affect consciousness, have not the normal afferent check from the sensory processes which should influence them. Of this the subject is quite unaware. Restraint may be effective before sensibility is subjectively lessened; we are often determined by influences which do not enter our consciousness. Some years ago a rather distinguished student was working here who was a really great cyclist. He had won many of the best cycle races in the country. Soon afterwards he came to me about some symptoms he felt in his hands, and on examining him I found such extensive loss of sensibility to pain as could only be explained by syringomyelia. I had to advise him to give up all severe exertion, including the races to which he was devoted. We must remember that the central motor nervous system represents the muscles, and all prolonged muscular effort has an influence on the spinal cord similar to that which it has on the muscles, and this disturbance of the circulation, and accumulation of the products of fatigue, resulting from severe exertion, must be of a nature to increase any morbid processes, the extent and progressive tendency of which we cannot safely estimate. I do not know what has become of him. But the history of this woman seems to show that severe exertion is unwise for such a sufferer. Hence it is very important to be familiar with the early symptoms of the malady, and to discover its existence, so that the life of the patient may be wisely regulated. The fact that a sufferer can generally feel well a touch, although pain is perceived dimly or not at all, explains the common ignorance of the malady, in spite of the frequency with which its presence is indicated by spontaneous pain. From this the patient whose case we have been considering was entirely free. It is often also accompanied by a sense of coldness, without any objective indication of the temperature which is complained of. These subjective sensations seem due to the irritation of the conducting fibres within the cord which are in process of destruction, and the pain may cease when sensibility is lost.

But tactile sensation is often impaired. It is very little affected in this patient, only in the front of the right thigh. Sensibility to temperature is lessened in the regions indicated in the diagram by oblique lines. Often the loss is almost as extensive as that to pain. The sensitiveness to pressure is often also lost, and that of the deeper structures may be impaired as well as that of the skin, although often not in corresponding degree. The cavities may extend higher up, into the medulla and pons (syringo-bulbi this is termed), and impair some of the cranial nerves, especially the sensory part of the fifth. The dissociated analgesia of this affection may remind you of the common loss in tabes, in which the perception of pain is so commonly lost and that of touch so rarely. When the analgesia involves the deeper structures an arthropathy may occur in syringomyelia, very similar to that of tabes. But this is most common in syringomyelia in the arms and in tabes in the legs. Other collateral consequences of sensory defect are also found which I cannot now even mention. I have brought the case before you briefly to illustrate the diagnostic difficulty, and to impress on your mind the fact that we must always beware of the significance of a superficial similarity, and remember that the resemblance may be due to very different causes, and may almost cease, on careful scrutiny.

Remarks

ON

ANTISPASMODICS AND THE CURE OF SPASMS.

BY EUSTACE SMITH, M.D., F.R.C.P.

SENIOR PHYSICIAN, EAST LONDON HOSPITAL FOR CHILDREN;
CONSULTING PHYSICIAN, VICTORIA PARK HOSPITAL FOR DISEASES OF THE CHEST.

FOR the relief of spasm and the many distressing sensations which may be grouped under that head many kinds of treatment may be adopted. In the case of general convulsions and some forms of local spasmodic contractions we may act upon the nervous system generally, and make use of means which reduce its sensitiveness to morbid impressions. For this purpose we turn to the narcotics—opium, chloral, belladonna, the bromides, etc. But these remedies should never be used indiscriminately or without due consideration of the nature of the attack and the presence of a removable cause. They may form the main treatment of the case, or may be employed with the object of reducing general nervous excitement while special means are being used for the relief of local distress.

In certain forms of local spasm we may make use of remedies which are known to have a special sedative action upon the disturbed part, such as grindein in spasm of the respiratory tract; belladonna, chloroform, and codeina in intestinal cramps; valerian and asafoetida in the mysterious functional nervous derangements which are massed together under the head of "hysteria."

Again, we may seek to produce a tonic effect upon the system as a whole by the use of strychnine and nuxvomica, ergot of rye, sulphate and valerianate of zinc, quinine, arsenic, the stronger preparations of iron, and drugs of similar action. These, however, are of little value during an actual prooxysm, but exert their influence gradually by reducing the general nervous irritability, so that the system becomes less intolerant of morbid stimuli, and ceases to respond with such petulant activity to disturbing influences. Their action in this respect is deliberate, and rarely of more than passing value, unless persevered with for weeks or even months at a stretch.

The above may be said to include the special classes of drugs which are generally understood by the term "antispasmodic"; but they do not embrace the whole subject of the cure of spasm. The best and only satisfactory kind of antispasmodic treatment is that which strikes at the root of the evil and suppresses the irritant to which the disturbance is due. In many persons, especially in children and young women, the source of the ill is often a deranged condition of the digestive organs, and when this is remedied the spasm ceases. General and partial convulsions, tetany, and many kinds of tonic and clonic spasm, both general and local, may be induced directly by peripheral and especially by gastro-intestinal irritation. Children, with their immature and impressionable nervous systems, are curiously amenable to these influences, and in some such subjects any form of irritation seated at any part of the body may be capable by reflex mechanism of setting up automatic and irresistible contraction in voluntary or involuntary muscles. The tendency to such morbid response to stimuli is greatly enhanced by a lowered state of the general health. In the case of tetany, for example, the disorder rarely attacks a healthy, sturdy subject, but is met with almost invariably in children whose nutrition is temporarily at fault, either from natural delicacy or domestic mismanagement. The spasmodic contractions of this complaint seem to be the consequence, more or less direct, of toxic absorption from the alimentary canal. A poison is generated which shows a special preference for the motor fibres and ganglion cells of the anterior horn of the spinal cord; and, in cases of long standing, atrophy and sclerosis have been noted in these cells, combined with some thinning of fibres. More than this, however, is required to explain the mechanism of tetany, for autointoxication is common in children of all ages, while tetany is only an occasional consequence of gastric dilatation and decomposition of food. It seems

probable that auto-intoxication heightens the natural irritability of the nervous system, and prepares it to respond with exceptional briskness to reflex stimuli, but that the actual attack, like the convulsions of rickets, is the direct consequence of reflex mechanism, and cannot occur without it.

In the management of such a case the true antispasmodic treatment consists in putting a stop to the digestive derangement which is the cause of the symptom. We clear away fermenting food from the bowels by a full dose of rhubarb and soda, arrest excessive intestinal secretion, and by a careful diet, in which a judicious restriction of milk and other fermentable elements in the food takes a foremost place, seek to restrain the formation of toxins in the alimentary canal. These measures may have to be reinforced afterwards by tonic treatment and the use of the accepted antispasmodics in order to invigorate the nervous system and allay its irritability; but these remedies have little value at the beginning of the treatment, and begin to be useful only when the disturbed digestive functions have been attended to and brought into a healthy state.

But it is not only tetany which can be set up by the irritation of gastro-intestinal disturbance. In neurotic subjects—especially in neurotic children—general convulsions and even modified muscular contractions, which bear a close resemblance to those which are characteristic of the so-called "*petit mal*," may be induced by irritation arising from this source. It is far from uncommon to find the instability of the nervous system, which may be called a normal state in the infant, persisting in growing boys and girls to the age of 10 or 12 years. As a consequence, confused and purposeless muscular contractions and convulsive movements, such as are familiar enough in the rickety infant, may be met with at an age which suggests a graver view of the attacks than a truer conception of their real nature would be able to support. These cases are often called "epilepsy," and even treated as such with long courses of bromides. It is not for the first time that I venture to protest against the practice of lumping together all cases of convulsions in the growing child under this one misleading designation. I maintain that so long as the seizures occur only in the course of a digestive disturbance, or are accompanied by a rise of temperature, or happen in a child who is suffering from any form of peripheral irritation, or, indeed, in one who is not, to all appearance, in his normal state of health, we are entitled, whatever may be the age of the child, to indulge a hope that the seizures will cease when the cause has been removed and adequate measures have been taken to prevent its return. The term "epilepsy" cannot fitly be applied to such avoidable attacks as these, but should be confined to cases where the patient seems to be well, with nerves normally at rest and no sign discernible to lead to a suspicion of the onset of any such untoward visitation.

There are other forms of functional nervous derangement which may arise from digestive trouble and acid fermentation in the bowels. The fantastic muscular twitchings which go by the name of "tics" and "habit spasms" usually owe their origin to this cause. These movements by their persistency occasion much distress to parents, and are often the despair of the medical attendant, especially if he follow the prevailing method of attempting to control them by the use of nerve tonics and antispasmodics. Under such treatment they are, no doubt, intractable enough; but if the spasms are accepted as a significant sign of intestinal disorder, and treated by proper measures for its relief, no special difficulty is found in keeping them in check. Antacid and stomachic remedies, combined with a rigid diet from which sweets and fruit are carefully excluded, and starch allowed only in the form of bread and toast, soon give rise to a surprising change. Not only do the movements cease, but the general nervous unrest disappears; and there is a welcome return to a normal state of physical and mental tranquillity, which a recurrence of the morbid stimulus is no longer able to disturb. Early treatment on these lines is, however, of great importance, for if the movements have been allowed to continue for months unchecked until the habit has become confirmed, more difficulty is found in bringing them to an end. Still, even in these cases, diet and the administration of arsenic in good doses, combined with alkalis in a bitter infusion, will often produce very

encouraging results, especially if the patient can be induced by hopes of reward to bring his own power of self-control to our help. Punishments are useless.

Head shaking, again, and rhythmical rotatory movements of the head combined with nystagmus (the spasms nutans of infancy) are also commonly due to digestive troubles in a neurotic subject. The milder attacks often yield readily to a dose or two of rhubarb and magnesia, especially if it be combined with a restriction in the quantity of the fermentable element of the food. But in the severer forms of the complaint special tonic treatment will always be required in addition. When the digestive functions are working satisfactorily, iron should be given, and if the child be over 12 months old, a meal of pounded mutton or chicken should be included in his dietary. Spasmus nutans is, of course, a different thing from the "nodding convulsion" (cloniasia nutans). The latter is only seen in epileptic idiots, and is incurable.

Although it is the digestive tract which is most frequently at fault in cases of reflex spasm, it is not the only source from which the evil influence may spring. Any irritant, wherever situated, even a mild one if sufficiently prolonged or often renewed, may lead in a suitable subject to some such morbid response. A common example of this is seen in the nervous commotion which is excited in some children by post-nasal irritation due to adenoid vegetations. The growths themselves are probably concerned in the disturbance only indirectly. Alone they excite little irritation unless very numerous, but by their presence they render the naso-pharyngeal mucous membrane morbidly susceptible, so that it readily becomes the seat of a troublesome catarrh which exerts a curiously teasing influence upon the nervous system. General convulsions sometimes, and laryngeal spasm commonly, owe their origin to this source of worry. The more I see of laryngeal spasm, either in the form of laryngismus stridulus or stridulous laryngitis, the more convinced I become that in these cases the source of the irritation is the naso-pharynx. To me catarrhal croup has come to mean adenoids, and to suggest at once treatment by measures directed to the suppression of a post-nasal catarrh. The same thing may be said of simple laryngeal spasm without catarrh (laryngismus stridulus). Children who are attacked by these dangerous seizures are almost always sufferers from adenoid vegetations and post-nasal irritation. They are also often the subjects of rickets, but this is not always the case. It is a mistake to assume, as is commonly done by writers upon this subject, that laryngismus is a complication peculiar to the rickety state. No doubt in that phase of malnutrition there is a special irritability of the nervous system which so heightens its response to disturbing influences that the morbid rejoinder can be provoked by a comparatively moderate impression. But the occurrence or not of spasm depends less upon the constitutional state of the child than upon the nature and strength of the irritant. If the provocation be adequate, spasm may be induced in a neurotic subject at any period of infancy and childhood in rickety and non-rickety subjects alike. Repeated observation has convinced me that morbid contraction of the laryngeal muscles occurs almost solely amongst the sufferers from adenoids, and is to be ascribed directly to naso-pharyngeal irritation. Some time ago I recorded several cases of laryngismus affecting newborn infants, in whom the frequent spasms involved the gullet as well as the larynx, so that swallowing became almost impossible. All these infants were suffering from adenoid overgrowth and severe catarrhal obstruction of the nasal passages; and it was interesting to note that the force and frequency of the attacks varied in exact proportion to the greater or less intensity of the naso-pharyngeal distress. In cases such as these, then, as in tetany, the true antispasmodic treatment consists in measures which allay the local uneasiness and put a stop to the nervous commotion by removing the cause which has brought it about.

These measures consist in applying remedies locally to the naso-pharyngeal mucous membrane. This is done most easily in young children by dropping medicated fluids into the nostrils and allowing them to trickle down into the pharynx. One of the best of these is resorcin dissolved in normal saline solution (2 to 5 grains to the ounce). Of this a few drops may be instilled into the nostrils several times a day as the child lies on his back.

If the spasms are violent and repeated the local treatment must be reinforced by the internal use of special antispasmodics. In the case of the larynx, the best of these, beyond all comparison, is the liquid extract of grindelia—a drug which has a very decided sedative action upon spasm of all muscles connected with the respiratory apparatus. It may be given in doses of ten to thirty drops, in water flavoured with the liquid extract of liquorice and well sweetened with glycerine, every four hours. In the case of young patients grindelia is an antispasmodic of the utmost value. In asthma, in whooping-cough towards the end of the spasmodic stage, and indeed in all varieties of respiratory spasm, we may turn to grindelia with full confidence in its beneficial effect.

Another instance of reflex spasm is seen in the rigidity of the muscles of the neck which not infrequently occurs in cases of acute otitis. The child lies in a state of seeming stupor, but is not entirely unconscious and shows no sign of pain. He holds his head stiffly and slightly retracted, and whimpers if it is moved, especially if an attempt is made to bend it forward. The stiffness ceases at once when the purulent contents of the tympanum are allowed to escape by puncture or rupture of the membrane.

The above are the most prominent and persistent varieties of reflex spasm, the only rational treatment of which consists in measures which produce a direct impression upon the source of the nervous trouble. Other minor examples of spasmodic muscular contraction of similar mechanism are met with in daily practice. The severe nocturnal cramps in the limbs which are a common subject of complaint by the habitual dyspeptic are due to acidity, and can be put a stop to by an alkaline draught taken at bedtime. Acid collections in the caecum and the small intestine near by may set up cramp in the bowel by causing spasmodic contraction of its muscular coat, and so penning up flatus and preventing it passing away. The painful over-distension which is apt to ensue can be satisfactorily relieved by the administration of the insoluble alkalis, such as the heavy carbonate of magnesia, combined with a quarter or a third of a grain of codeine given several times in the day. Codeine is a valuable sedative in all forms of abdominal pain, and has the advantage over opium of interfering little with the regular action of the bowels. Under certain conditions, however, belladonna is to be preferred. Spasmodic contraction of the muscular coat of the intestine may induce an obstinate form of constipation which sometimes amounts to impaction of the bowel, and resists the action of strong aperients given again and again. In most cases of this kind the difficulty can be overcome by repeated doses of the green extract of belladonna, giving a $\frac{1}{2}$ grain every three hours until the pupils begin to dilate. This, the first sign that the system is beginning to respond to the remedy, is followed quickly by relaxation of the intestinal spasm and copious relief.

In every case, then, of spasmodic contractions, either of voluntary or involuntary muscle, especially in such as occur in children, before resorting for their relief to nerve tonics and antispasmodics, we should search carefully for some sufficient signs of local trouble to which the nerve disturbance may be referred. In young people, especially in rickety infants and rapidly-growing boys and girls, our first thought should always be of reflex mechanism, and it is only when a fruitless examination has shown our suspicions to be unfounded that we can venture to lay this explanation of the symptoms aside. We are then obliged to fall back upon plain antispasmodic treatment. But even in this case every attempt should be made to keep the nervous system at rest by avoidance of undue excitement, attention to the regularity of the bowels, and in the matter of diet a careful moderation, not only in red meats, but in acid and acid-making articles of food.

The kind of antispasmodic treatment to be employed is of importance. In the case of true epileptic attacks, excessive dosing with large quantities of bromide is, I believe, a plan of treatment which is better avoided. By such means, no doubt, we may lessen the frequency of the seizures for a time, but sedatives alone have little power to put an end to them altogether. These remedies are best used as aids to the action of nerve tonics; as a means of quieting undue nervous excitement, while the more slowly acting drugs are given time to produce their bracing effect. Of the latter I rely chiefly upon ergotine given in conjunc-

tion with strychnine. To be effectual the dose of ergotine must be pushed, and this may be done without fear of ill consequences; indeed, little effect can be expected until a good dose is reached. Beginning with 3 gr. every four hours given in conjunction with $\frac{1}{10}$ grain of strychnine, the dose may be increased gradually to 10 grains, and every evening at bedtime a draught containing 20 grains or more of bromide of sodium may be given with infusion of senna and aromatics. In the case of children the most satisfactory results often follow this method of treatment, especially if it be combined with a free country life in a healthy situation. The seaside, or, at any rate, the neighbourhood of the sea is to be preferred. It is wise to occupy the child's mind with light employments which interest and amuse; and if he can share these with young people of his own age, who may be trusted not to irritate or excite him, it will be distinctly to his advantage.

Another example of universal spasm which has to be treated with general nerve sedatives is chorea. In the management of this complaint it would be difficult to name a sedative which has not been employed with more or less success. I have obtained very striking results in obstinate cases with ergotine prescribed in large doses in conjunction with strychnine in the same way as recommended for epilepsy. Recently I have been giving chlorotone in doses of 3 to 5 grains three times a day and have been well satisfied with the results. The remedy is one which decomposes very quickly and should, therefore, never be prescribed in combination with another drug. It is best given in "cachet" or dissolved in water sweetened with glycerine. A dose of 5 grains three times a day often causes some drowsiness. If this be so, the dose should be reduced to 2 or 3 grains after the first twenty-four hours.

But cases, such as the above, in which we are forced to rely solely upon the action of pure antispasmodic and tonic remedies for the control of the morbid phenomena—form—in early life at any rate—but a small proportion of the examples of muscular spasm which are being continually brought under our notice. As a rule in the young the phenomena are purely reflex, the impulse being derived from irritative action at some point of the periphery. In all such cases the employment of general sedatives must be made subservient to the more pressing needs of local medication; but these remedies are still useful as aids to the treatment to reduce the general nervous susceptibility while special local measures are being employed to put an end to the primary cause of the nervous distress.

A Clinical Lecture

ON

AMAUROTIC FAMILY IDIOCY.

DELIVERED AT THE HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND STREET.

By F. J. POYNTON, M.D., F.R.C.P. LOND.

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL;
PHYSICIAN TO OUT-PATIENTS, THE HOSPITAL FOR
SICK CHILDREN, GREAT ORMOND STREET.

AMAUROTIC family idiosyncrasy is such a rare disease that it may seem hardly suitable for a lecture such as this, but I have chosen it because I happen to have met with four cases in recent years, and have one of them to show to-day; and also another of them, minutely investigated after death by Dr. Gordon Holmes and Mr. Herbert Parsons, stands as one of the most complete cases on record, for it was studied by recent neurological methods. This disease is, too, a very remarkable one, and, though you may never meet with a case, a short time given to its study can hardly fail to direct one's thoughts to some interesting points in the study of medicine.

I think, to begin with, it is interesting to trace the gradual recognition of the disease, because this illustrates how the specialist may sometimes point out to the general physician some fact in medicine which has been previously overlooked—just as the general physician may sometimes throw an entirely new light upon a subject which at first sight would seem to be quite a special one. In 1881 Mr. Warren Tay directed attention to peculiar macular

changes in the eyes of an infant. The title of his contribution was "Symmetrical Changes in the Region of the Yellow Spot in Each Eye of an Infant," and an excellent picture is given of the condition in this paper, which was published in the first volume of the *Transactions of the Ophthalmological Society*.

Knapp († New York in 1885 recorded a necropsy, and in 1887 Sachs (B.) of New York, who has done so much to elucidate this disease, described the changes in the brain in a case under the title of "Arrested Cerebral Development." In his later contributions he named the disease amaurotic family idiocy, and defined the chief clinical features. A valuable paper by Mr. E. C. Kingdon and Dr. Risien Russell was published in the *Royal Medical and Chirurgical Society's Transactions for 1897*, under the title of "Infantile Cerebral Degeneration with Symmetrical Changes at the Macula," and since that time various writers have contributed to the literature and further elucidated a disease which was, as you see, first recognized by an ophthalmic surgeon through one of the most striking of its symptoms. American physicians have in particular made valuable contributions to the literature, and among the more recent of them Spiller has been prominent. I believe that almost every case recorded which is undoubtedly an example of the disease has occurred in a Jewish child, although Mohr described a case in an American. In all my four cases both father and mother were Jews and not related. It is a disease of infancy, and shows itself in the first year, usually before the sixth month and frequently about the third, and it is almost invariably progressive, and ends fatally somewhere in the second or third year of life.

If it were not for its rarity it would be a disease of the utmost importance, and for those who have charge of numerous Jewish patients a knowledge of its chief features must be of some value.

It is interesting that my four cases have been sent to the hospital as cases of rickets, because they have shown loss of power and general feebleness. Extreme rickets, we know, does occur among the Jewish poor; but I think we must remember that the mothers generally nurse their children, and unless they are hopelessly poor I hesitate to hurry into the diagnosis of rickets with breast-fed children. As you will see, there are probably no two diseases more unlike than rickets and amaurotic family idiocy when well developed; but the error arises, no doubt, because the medical man is not acquainted with the rarer disease, and, finding himself driven into the corner where we all in turn crouch, falls back, for the need of a name, on that comprehensive and elastic one of "rickets."

The usual history that is given by the mother is to this effect: The child was healthy for some three months after birth, and during that time there had been no illness. Then she noticed that instead of going forward the child began to go back and the muscles of the back and neck were becoming feeble. The real gravity of these signs may not be realized for some months, and then the suspicion grows that the child cannot see well, and that the expression of its face is dull and the mental state feeble. As the disease progresses there is complete inability to raise the head or sit up, and even to turn when lying down, though sometimes the arms are thrown over the head in a wild, purposeless fashion. The limbs are also enfeebled, although at first no visible wasting will be apparent. A very interesting symptom present in all my cases, but I believe not invariable, is the survival of an acute sense of hearing, which, coupled with the general nervous degeneration, causes the infant to start at any sudden sound. The result is striking, for when the child is lying motionless it starts at a sharp sound, almost as if an electric shock had been applied. The sense of taste is preserved. There may sometimes be curious vermicular movements of the fingers and hands and a general drowsiness. In the last stage the limbs may become spastic, the muscles are wasted, and the reflexes increased.

Although some writers have stated that the temperature remains normal, this is not invariable, for in one of my cases the temperature rose shortly before death to 103°. There were screaming and head retraction, ptosis, and finally coma. Yet the anterior fontanelle was not distended, and no sign of meningitis was present after death.

There is, then, in this disease a slowly progressive paralysis, unmarked at first by any startling symptoms, but relentless in its steady advance unless death be accelerated by some intercurrent malady.

There is another very important feature in amaurotic family idiocy—its tendency to appear in several members of a family. The unfortunate mother of this child lost her first from the same cause, and will, I fear, surely lose this one also.

The history of Kingdon and Risien Russell's cases is, however, far more striking. The first child died of this disease; the second was healthy; the third died; the fourth was healthy; the fifth, sixth, and seventh all fell victims. The two healthy ones were a girl and boy respectively. More cases, however, have been reported in females than in males.

Ocular Changes.

The ocular changes are most interesting and important, and were, as I have already mentioned, the means of the discovery of the disease.

In most cases there is a primary optic atrophy, although Tay detected some neuritis in the earlier stage. I have never seen a case yet in which the ocular sign of atrophy has not been already developed and distinctive. Coupled with this atrophy there is in the position of the macula lutea, a white, hazy appearance of the retina, in the middle of which area there is a cherry-red spot of colour, closely resembling the appearance found in embolism of the central artery of the retina. In the case here to-day these signs are exceedingly well marked, and their presence enabled me to clinch a diagnosis which was at first not quite obvious.

The explanation of the changes is given briefly under the pathology of the disease, and they remain constant until death, with trifling modifications. The pupils are equal, and when the atrophy is well developed become widely dilated and inactive.

Pathology.

The pathology of this disease is at once interesting and obscure, and it is only in comparatively few cases that a complete investigation has been made.

Macroscopic changes in the brain are seldom evident. Sachs, however, described in two of his cases a low type of development of the cerebral convolutions, and in three cases the brain seemed unduly hard. In one of my cases there was the same unnatural hardness of the cerebral tissues. In other cases no change from the normal has been observed at all.

Microscopical changes were demonstrated by Sachs in 1887 and 1892, and in 1897 Dr. Risien Russell with Mr. Kingdon gave a full account of the changes they had observed in one case, and that account holds good at the present date, though it can be supplemented by additional observations which result from the use of other methods than staining with the aniline dyes. In 1906 Dr. Gordon Holmes and Mr. Herbert Parsons made a very careful and extensive investigation into one of my cases, which was published in detail in *Brain*, 1906, p. 180. This confirmed many of the previous observations, emphasized the statement of Spiller in 1905 that the disease of the nerve cells is general, and also elaborated the nature of these changes. I must refer you to that paper for the details, which are too intricate for this lecture.

The great fact to grasp in the pathological anatomy is the remarkable general and extreme disease of the nerve cells. It would appear to be a primary cell disease, and the changes in the fibres are apparently secondary. We may even go a step further and say that this disease is primarily a disease of the interfibrillar protoplasm of the cells, the changes in the neurofibrils being secondary.

The cell destruction may be most extensive; thus, in my case not a single normal cell was found by Dr. Holmes in any part of the central nervous system he examined, and the same was true also of the dorsal ganglia and ganglion cells of the retina. Spiller has found peripheral nerve changes. The tough consistence of the brain was the result of a secondary proliferation of the neuroglia.

It is also important to recognize that the disease of the nerve cells is not a result of inflammation, for there are no vascular signs of either acute or chronic inflammation.

The changes in the nerve cells are: Swelling of the cell body with frequently gross alteration in shape; disappearance of Nissl bodies, excentric position of nuclei, vacuolization of the protoplasm.

It may well be expected that the explanation of the cause of such a disease as this is beyond us. The very fact that, so far as I am aware, it is almost invariably met with in the Jews points at once, I think, to some very obscure disorder of metabolism.

The inevitable progress of the disease does not suggest an arrest of development but some active process. A bacteriological cause is improbable, for there are no positive facts in its favour, and my case was entirely negative, and the absence of vascular changes, the age, and racial nature of the disorder make such an explanation unlikely.

It does not appear from the microscopical evidence to be a pure atrophy, and I can get no further than the statement made by Holmes, Parsons, and myself in our paper that it is due "to some inherent bio-chemical property of the protoplasm of the cells." The only *post-mortem* examination I have seen showed no obvious changes in any of the viscera or internal glands which even suggested that they were at fault, but you will readily appreciate that a decisive statement on this point would be impossible with such a scanty experience. If there is some internal secretion at fault, at present no one, I believe, has discovered the gland that is to blame.

The explanation of the remarkable fundus changes comes next. Treacher Collins, Holden, Mohre, Shumway, and Mary Buchanan, and more recently H. Parsons, have written upon this point. There is profound disease of the ganglion cells in the retina, and at the fovea the disease may become so extreme that there is atrophy of the retinal tissue; and possibly this atrophy may even result in an actual destruction of the retina at this spot, as seemed to have occurred in my case. Whether this be so or not, you can imagine to yourselves the condition that results. We have the retina spread out over the vascular pink choroid, and where it is thinned by disease it is evident that this coloured background when illuminated by the ophthalmoscope will shine through with particular brightness and colour, and by contrast with the surrounding less diseased parts this greatly damaged area will appear as a bright cherry-red spot. The contrast is rendered all the greater because it would appear that the retina around the fovea may become oedematous, or, more probably, through swelling of the diseased cells, thickened, thus cutting off the colour of the choroid and forming around the cherry-red spot a whitish zone. The optic atrophy is due to the extensive disease of nerve cells and nerve fibres.

There are some remarkable cases on record which only in some details resemble amaurotic family idioey.

Spiller, whose name I have already mentioned, found changes in the nervous system which he believed to be identical with those of amaurotic family idioey in two children, one of which was 9 years of age, the other 8 years, who were not suffering clinically from this disease. These two children were mentally defective, but were not blind, and they would appear to be quite exceptional cases, which we must bear in mind when we dwell on the entity of amaurotic family idioey. This is the more needful, because Falkenheim mentions a case of this disease in which the ocular signs were not present.

I have never myself recognized any case of an aberrant type, all the four I have published were classical in their onset, symptoms, and course. There is one case (Peterson's) which had survived to the age of 5 years, but in the absence of a necropsy, one is obliged to suspend decision as to its exact nature.

In this country I am not aware of a single case published which has not occurred in a Jewish child, but I believe that this is not an invariable rule, although there can be no doubt that it is to a great extent a racial disease, and far more so than the condition diabetes, which at once occurs to one as also more prevalent in the Hebrew race.

When confronted with a case of this kind, which is so mysterious in its nature and so hopeless in its prognosis, it is only natural to attempt to add any fact one can, that is of the least importance. Dr. F. Mott, from his laboratory, has done this in the case you see to-day, for he kindly had the blood and cerebro-spinal fluid examined by Dr.

Candler by Wassermann's reaction, and has informed me that they both gave a negative result. This bears out so far the clinical experience of these cases that they are not a result of inherited syphilis, and is, I believe, a new observation on the disease.

Treatment.

It is quite useless for me to speak of the treatment. Russell and Kingdon tried numerous remedies of all kinds in vain in their series. I should not even follow Hirsch's suggestion that the mother should not nurse any child she might have in the future. One feels that this is but a faint hope. Further, should the child not show any sign of the disease, we must remember that not every member of a family need necessarily suffer whether nursed or not: Sachs, in fact, has already pointed out that it is of no avail.

I have tried one of the organic phosphorus compounds in this case, but I see no good result at all in consequence, and I think we need some much more subtle remedy than this.

Diagnoses.

You will readily understand that the great point in the diagnosis of these cases is really a knowledge of the disease. It is so rare that we never think of it, and perhaps have never heard of it, and then, of course, we must lose our bearings.

It has no resemblance at all to rickets, except in so far that the child is muscularly feeble, and I need not dwell on the extreme dissimilarity of the two diseases.

Cerebral diplegia is more likely to cause confusion, but the distinction is usually an easy one. For example, take such a case as this which I saw recently. A child of 7 months was brought for paralysis, which had been noticed by the parents soon after birth. The boy's head fell back from weakness of the cervical muscles, he snorted when asleep from weakness of the palate, and all four limbs were spastic, but there were no ocular changes. You will see that the spasticity was an original symptom, but it is not an early symptom in amaurotic family idioey. Then, again, he was no worse than he was at 2 months of age; in fact, he was a little better. There was no blindness and no curious starting at a sudden noise. The reflexes were greatly exaggerated.

In another case there was double optic atrophy and consequent blindness, but the disease was not advancing; there was the same spasticity, and an entire absence of the macular changes of amaurotic family idioey.

In some congenital syphilitic lesions of the brain there may be a progressive downhill course, or there may be a downhill course in which the steps are marked by sudden exacerbations of symptoms. In such cases epileptic attacks are common, and there may be other stigmata of congenital syphilis including choroidal changes, but not the characteristic ocular changes of amaurotic family idioey. The history of stillbirths, miscarriages, or syphilis in the parents is often met with in such cases, but this is not the experience in the disease we are now considering.

Whether or not there are cases of progressive idioey met with in asylums for children, which resemble this disease closely, I am not competent to state, but if they exist they must be very exceptional, I think, for even Spiller's cases did not show a clinical resemblance. Hydrocephalus can be at once excluded because that condition is not present in amaurotic family idioey.

Post-basic meningitis, although it may give rise to blindness and paralysis, is acute in its onset and associated almost invariably from the first with such symptoms as fever, retraction of the head, convulsions, and vomiting. There are no macular changes and the cerebro-spinal fluid obtained by lumbar puncture will at once differentiate the disease.

Possibly a cerebral tumour in an infant might show some resemblance, but I have never myself met with any case in the least resembling one of these.

Cretinism could not possibly be a cause of difficulty.

AN EPIDEMIC OF TINEA CRURIS.

By J. ODERY SYMES, M.D., D.P.H.,

PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL.

RINGWORM of the scalp and body occurring in epidemic form in schools is familiar, but ringworm of the groin, fork, and axilla is not of such common occurrence except in tropical climates; its appearance in epidemic form during the last three years at the universities and in our public schools is my reason for publishing the following notes.

Tinea cruris has also been called *tinea marginata* or *eczema marginatum*. In the majority of cases I have seen the lesion starts in the fork or inner surface of the thigh, where it is touched by the scrotum. A red patch, looking like an area of chafing, appears, and rapidly spreads down the inner side of the thigh and backwards towards or behind the anus. The spreading edge is raised, dry, scaly, or papular, whilst the portion within the ring is moist and eczematous. Gradually extending from the margin, the lesion in the lower extremity may almost reach the knee, and in the axilla may reach the level of the nipple. There does not appear to be any tendency to a spontaneous return to the normal on the part of the skin within the growing margin. The hairs are not affected and do not fall out. Beyond slight itching, there are no subjective symptoms. On the trunk and limbs of infected persons there may often be found patches which can in no way be distinguished from ordinary ringworm of the body (*tinea circinata*).

On March 8th, 1907, a boy presented himself, suffering from a condition I diagnosed as *eczema intertrigo* affecting the scrotum and inner side of the right thigh. At the end of the term, about the first week in April, the condition showed no improvement, and he went under the care of his doctor at home, Dr. McLannahan, of Stonehouse, who very kindly wrote to me, saying that he regarded the case as one of *tinea marginata*, a condition he had met with amongst soldiers and amongst stokers in the P. and O. service. This boy was apparently well by April 21st, and he returned to school a few days later, and had no recurrence. On May 31st, 1907, a second boy from the same house was seen with *tinea marginata* of the axilla. An undress parade of the boys in the house led to the discovery of 9 other cases, 2 having the disease in the axilla, and the remaining 7 in the groin or fork. A second inspection of the house a month later led to the detection of 2 more cases; the fourteenth case appeared twenty-four days later, and the 21st cases were found thirteen and eighteen days after this. In all, there were 16 cases, all in one house of about forty-five boys.

Clinically, there was little to note about the cases. In a few, which were of old standing, the rash extended as low as the lower third of the thigh and backward behind the anus. Not uncommonly a few spots, the size of a three-penny-bit, were found on the thighs, calves, trunk, and more rarely on the arms. These isolated spots were drier and more scaly than the patches in the groin or axilla, and readily yielded to treatment. The rings gave rise to no symptoms beyond slight irritation. The average length of time under treatment was five weeks. Three cases recurred, two after an interval of six weeks, and one after the lapse of four months.

Scrapings from the growing edge of some of these cases were examined microscopically, both by myself and by a

local bacteriologist. In all, a large-spored ringworm fungus was found.

Treatment was alike in all cases. The superficial epidermis was removed first, and then an antiseptic ointment was applied. To remove the epidermis I employed a solution of 40 grains of iodine with 20 grains of potassium iodide in an ounce of methylated spirit. Two applications were generally sufficient; then the parts were treated morning and evening with an ointment containing half a drachm of precipitated sulphur and half a drachm of ammoniated mercury in an ounce of lanolin. A few boys were treated according to a suggestion of Dr. McLannahan: the affected parts were painted every other day with a camel-hair brush soaked in oil of terebinth. rect., and the following ointment rubbed in every night: Sulph. precip. ʒss, hydrarg. amm. ʒss, acid. salicyl. gr. x, lanolin and vaseline aa ʒiv. In both cases the applications sometimes gave rise to severe smarting, but this was of short duration, and relieved by smearing with vaseline. Cases seen early and treated by this method were well in three weeks; old-standing cases took, of course, longer.

The factors common to all the boys who suffered in the epidemic were as follows: With one exception, they were all senior boys, members of the First Fifteen, using the same lavatory and bathroom. They did not all belong to the same dormitory, and there was no suspicion that they wore each other's football or running togs; indeed, one boy who suffered was not allowed either to run or play football on account of a chronic cardiac lesion.

The precautions taken to prevent the spread of the infection were as follows: All the boys in the infected house were stripped and inspected about every three weeks. All who were detected with the rash were made to sleep in the same dormitory, which was reserved for this purpose: they also had the exclusive use of a separate changing and bath room and water-closet. For baths and ordinary washing purposes Parke Davis's germicidal soap was used. All towels from the infected changing room were disinfected, and also the underclothing and running kit. The walls of the changing room and lavatory were washed down with disinfectant at the termination of the outbreak. The infected boys were not withdrawn from school work nor from the common dining-room. When the rash in the fork was profuse they were not permitted to join in the school runs.

These precautions were entirely successful; no other house was infected, and no cases have appeared during the subsequent fourteen months. During the period covered by this epidemic I saw in other schools several cases of body ringworm (*tinea circinata*); 2 isolated cases occurred in a boys' school, 1 in a girls' school, and 7 in a school for junior boys. None of these cases assumed the type of *tinea cruris*.

In my own mind there is no doubt that the outbreak was caused by the common use of the hot bath, or by the boys using each other's towels. Probably the growth of the parasite was encouraged by the moist, hot atmosphere of the bathroom, while the vigorous rubbing which boys give to the forks, groins, and axillae decided the points of inoculation. It has sometimes been thought that infection is carried in clothing, and that chairs and water-closet seats may harbour the parasite, but in the outbreak under consideration these factors could be eliminated.

Tinea cruris resembles *tinea circinata* in that it attacks patients after the period of puberty; but it is probable that there are two distinct parasites causing these conditions, for in *tinea cruris* the hairs are never attacked. The parasite of *tinea cruris* shows a larger spore and a freer growth of mycelium than *tinea megalosporon*; it is also very much easier to find in scrapings taken from the growing edge of a ring. These differences may be due only to the site in which the fungus has grown. In order to settle this point it is desirable that scrapings should be taken and growth obtained on Sabouraud's medium.

THE annual general meeting of the Society for Training Teachers of the Deaf and for the diffusion of the German (pure oral) system will be held at 33, Cavendish Square, W., on Wednesday, May 26th. Sir Melville Beachcroft, Chairman of the London County Council, will take the chair at 3 p.m.

A CASE OF LANDRY'S (ACUTE ASCENDING) PARALYSIS: RECOVERY.*

By C. H. CATTLE, M.D. LOND., F.R.C.P.,

PHYSICIAN TO THE NOTTINGHAM GENERAL HOSPITAL, AND TO THE
SHERWOOD FOREST SANATORIUM FOR CONSUMPTION.

For the following notes I am indebted to Drs. J. R. Edward and W. M. Sadler, house-physician and assistant house-physician, Nottingham General Hospital:

The patient, a collier, aged 23, employed on the "pit bank," was admitted to the Nottingham General Hospital on January 20th, 1903, having been ill about twelve days.

Previous History.

He had been addicted to an occasional indulgence in alcohol, but was not a constant "soaker." There was no history of syphilis, diphtheria, or lead poisoning. Some months back he had gonorrhoea. He had never been abroad. The family history was unimportant.

Present Illness.

A few days before the attack the patient had a drinking bout, got wet through, and sat for some time in his wet clothes. After this he complained of lassitude and general muscular aching.

On January 8th he felt "starved" and sick, and vomited slightly. The next day he had a numb feeling under the nails of both hands, as if the fingers had gone to sleep. By night the arms were involved as far as the elbows. Next day the arms and feet felt very cold and numb, and there was marked muscular weakness of all four limbs and of the trunk. Face not affected. He just managed to sit up once in bed, but could not dress himself or hold anything in the hands. The limbs twitched a good deal and ached. Drowsy in the day, wakeful at night. Appetite good. Bowels were moved by medicine. There was no loss of control over the bladder, except on one occasion, when he was being lifted on to a stretcher. About a week after the onset the eyelids and mouth became affected. He could only see through the slits of his eyes, and the drooped lids. No headache or other pain beyond aching in the limbs. Three days after the onset he began to be troubled with cough and phlegm.

Condition on January 23rd, 1903.

He is a man of healthy appearance, but is perhaps a little oppressed. Laid on back. Troubled with weak, ineffectual cough. Mouth dry (full doses of water being given). Mucous membranes of normal colour. Tongue moist, red, a little furred, gums normal. Pulse 100, moderate tension, regular. Respirations 23. Temperature normal. Double ptosis of upper lids, which cannot be raised above 4 in. Slight mucopurulent discharge from conjunctiva. Pupils equal, react to light and accommodation. Internal and external recti on both sides markedly weak. No nystagmus. Double weakness of facial nerve seen on trying to smile. Palate moves well. Tongue protruded straight. *Upper limbs:* No muscular wasting, but almost complete symmetrical paralysis. All muscles respond to faradism, except flexors of first and second fingers of right hand. No reaction of degeneration. *Lower limbs:* Knee-jerks absent. No ankle clonus or plantar reflex. No wasting of muscles, but great weakness. Some slight movements can be performed, others not at all. All muscles react to faradism and galvanism. No reaction of degeneration. *Sensation:* Everywhere normal. *Trunk:* The intercostal muscles are paralysed and respiration is carried on by the diaphragm. Superficial reflexes absent. The recti abdominis appear almost completely paralysed and the abdominal wall is lax. *Speech:* is blurred owing to weakness of the facial muscles; no hoarseness. *Heart:* Sounds normal, apex beat in fourth interspace just external to the nipple. *Lungs:* Slight dullness at bases, but no definite change in breath sounds. *Mental condition:* Bright when he is spoken to, drowsy at other times.

April 23rd: There is now free movement of the ribs in inspiration in respect both of expansion and elevation. The umbilicus moves upwards when he attempts to contract the recti. Facial and ocular muscles now normal. Great wasting of all small hand muscles, also forearm muscles, extensors more especially. Biceps wasted, but can be voluntarily contracted. All other muscles of upper arm are wasted and powerless. *Sensation normal.* *Lower limb:* Cutaneous sensation normal. Muscles tender on pressure or passive movement. Great muscular wasting in thigh, leg, and foot, with plantar flexion. He can slightly bend knee, move toes, and flex ankle. These movements cause pain. Slight glossiness of skin of foot. There is a general tendency to sweating.

July 23rd (six months after admission).—There has been considerable improvement in the arms, which he can raise so as to get hold of the bar at the bed-head. Can sit in a wheel-chair, but cannot propel himself. Patient discharged from hospital.

February 28th, 1906 (seven months after discharge from hospital).—Looks plump and well. The shoulder and arm muscles are in good condition, movements of shoulder and elbow well performed. The extensors of the forearms and the small hand muscles are atrophied, more so on the right side. There is permanent flexion of the two distal phalanges of the fingers, the proximal one being extended. He can propel himself in a

wheel-chair, but can do no useful manual work. There is wasting of extensors of the leg, consequently there is extreme foot-drop and plantar flexion of the toes. Knee-jerks not obtained. Can flex and extend the knee to some extent. Muscles moving the hip are very weak, and he cannot stand even when supported on each side.

Treatment.

He was at first given liq. strychnin. mv. with tinct. belladonna. mx, every two hours. Both these drugs are respiratory stimulants, and the only chance of recovery appeared to be in stimulating the respiratory centre. The belladonna was given also with the object of checking secretion into the bronchial tubes, where it tended to accumulate owing to lack of expulsive power. The belladonna after a few days' use caused a little noisy delirium at night, which was treated by a bromide and chloral draught. After the first ten days the strychnine alone was given. On March 2nd sodium salicylate was given on account of the muscular pains. To this bromide of potassium and hyoscynamus were afterwards added. The strychnine was retained. Massage and galvanism were regularly given during the latter part of the patient's stay, but were not well borne on account of the muscular tenderness.

The group of symptoms known as Landry's paralysis has been known since 1859, when the disease was first described by the observer whose name it bears. It is more correct to speak of a group of symptoms than of a disease, because it is quite possible that the "symptom complex" in different cases has a different causation and variable pathological basis. By Landry's paralysis we understand an illness usually ushered in by sensory symptoms such as tingling, formication, etc., and then characterized by progressive loss of muscular power, commencing usually in the feet, involving in turn the legs, thighs, pelvic muscles, abdominal wall, arm muscles, respiration, deglutition, facial muscles, etc. There may be considerable loss of sensation, but more commonly this is absent, or confined to slight blunting at the tips of the fingers and toes. Most cases end fatally, especially when the respiration is affected, death occurring usually about the end of the first week, if not earlier, or it may be deferred three or four weeks. In at least two respects this case is remarkable. First, it is distinctly stated in the notes that the arms were affected before the legs. This occurrence certainly runs counter to the commonly accepted notion that the paralysis invariably commences in the legs and ascends the body segment by segment, until its progress is either stayed, or life comes to an end by reason of the importance of the structures involved. But we are told on the authority of the late Dr. Ross² that Landry himself stated that the malady might commence in either pair of limbs, and that the march of the paralysis might be sometimes described as "centripetal" rather than "ascending." Occasionally both the arm muscles and those supplied by the bulbar nerves have been affected before the legs. In the second place, this case is remarkable inasmuch as, notwithstanding the almost complete paralysis, the patient recovered. When I first saw him he lay almost motionless, breathing rapidly, and of somewhat dusky appearance. When spoken to, he threw his head slightly backwards to enable him to see through the fissure left by his drooping lids. In fact, he seemed to be hanging on to life by a thread. Every time I visited the hospital I expected to hear of his death. When asked how he was he always said, "All right," and probably his calmness and pluck had much to do with his recovery. It is impossible to say why certain muscles and nerves were spared and others affected. The muscles of the legs, arms, and trunk, including intercostals, were absolutely powerless. The muscles supplied by the brachial plexus were all involved, yet the phrenics which arise from the cord immediately above were spared. The pneumogastrii, glosso-pharyngeals, and hypoglossals seem to have escaped, while the muscles supplied by the third, sixth, and seventh were affected. The temperature at first was normal. About the sixth week it reached 99° in the evening. This, practically afebrile course, conforms to the usual type.

Exposure to cold and excess in alcohol are well-recognized causes of Landry's paralysis, and both of these co-operated in the etiology of the case before us. It has also occurred during convalescence from small-pox, typhoid, influenza, measles, and diphtheria. It has occasionally supervened in connexion with the puerperal state, syphilis, septicæmia, and phthisis.³ It is three times as common in men as women.

As regards diagnosis, there is room for doubt whether the lesions in this case were in the spinal cord or in the

* Read before the Nottingham Medico-Chirurgical Society.

peripheral nerves. At any rate, it was not a case of ascending myelitis leading to rapid and extensive softening of the cord. This is shown by the preservation of faradic excitability, of the functions of the bladder and rectum, and absence of tendency to bedsores, or of anaesthesia. A certain mystery has always hung over Landry's paralysis because it has so frequently happened that no morbid changes in the nervous system have been discovered after death. The disease was capable of abolishing function and of destroying life, without leaving behind any lesion or demonstrable alteration of tissue to indicate in what manner those results had been brought about. There are doubtless cases in which the nerves and spinal cord have been examined by modern methods and no pathological changes have been found. In rapidly fatal cases the action of the poison on the nervous tissues may be sufficient to cause death before characteristic changes of structure have had time to develop. On the other hand, many of the earlier cases occurred before it was customary to examine the peripheral nerves, so it is probable lesions in some cases have been overlooked. When inflammation involves all the elements of a mixed nerve it is usual to find that both motion and sensation are affected. In the case before us we may regard the lesion as principally affecting the whole system of lower motor neurons. The axis cylinders of the motor nerves are outgrowths of the ganglion cells of the spinal cord, medulla, and pons. The chief stress of the destructive process would be found in some cases in the peripheral nerves, and doubtless most often there because of their distance from the centre, and in others in the ganglion cells themselves. And here we can see an explanation why motor power has been recovered in some parts of the body and not in others. So long as the nerve cells themselves are not destroyed, there is possibility of regeneration of axis cylinders and of recovery of muscular tone and motor power, while if the cells themselves undergo degeneration there is permanent muscular atrophy and motor paralysis. This has occurred notably in the cell groups innervating the extensors of the forearm and toes and the small hand muscles. Although the morbid process has exercised a selective action on the motor fibres of mixed nerves, it is probable there has also been interstitial neuritis, which by pressure would cause irritation of sensory fibres. In this manner the tenderness and pain in many of the muscles can be accounted for. Neither hyperaesthesia or anaesthesia of the skin occurred, which appears to show that nerves containing sensory fibres only were only slightly affected, if at all.

Dr. Michell Clarke, in an interesting article in the *BRITISH MEDICAL JOURNAL* for September 12th, 1908, would limit the term "Landry's paralysis" to cases in which the lesion is confined to the anterior cornual cells, degenerative changes being nowadays demonstrated by Nissl's method, but which would have been passed over by earlier pathologists, thus giving rise to the notion that Landry's paralysis caused no morbid changes of tissue. This proposition apparently assumes that true Landry's paralysis is always fatal, for the morbid anatomy of a patient who recovers must always be more or less a matter of speculation. In the clinical sense I think the case I have related is sufficiently near the type of Landry's paralysis to be included under that name. Dr. Clarke goes on to describe a case of ascending paralysis due to toxic polyneuritis. There was great muscular wasting, the reaction of degeneration was present, and the patient died after an illness of about three months. At the *post-mortem* examination the peripheral nerves showed a very advanced degree of neuritis. But this was not all, for many anterior horn cells, especially in the cervical and lumbar enlargements, showed degenerative changes, such as disappearance of the Nissl bodies, vacuolation, and disappearance of the nucleus.

The physical and chemical properties of the poison causing acute ascending paralysis probably vary, and its nature in different cases is but little known. In one published case¹ micrococci have been found in the ganglion cells of the cord. Whatever the nature of the poison, it probably circulates in the blood like alcohol and the diphtheritic poison, and exercises a selective action on the lower motor neurons, the peripheral portion of which frequently suffers most. Another example of the selective action of a poison is that of the late effect of the syphilitic poison on the sensory protoneurons or on the pyramidal

cells of the cortex cerebri, producing the diseases known as tabes dorsalis and general paralysis respectively. The notion that Landry's paralysis is associated with no morbid tissue changes of permanent character can no longer be maintained, or that no muscular wasting occurs in cases that recover. This question was fully inquired into by the late Dr. Ross, and he "clearly showed that many cases have been reported which in the early stages were clinically indistinguishable from cases of rapidly fatal ascending paralysis, in which, when convalescence was protracted, some of the muscles became atrophied, and gave partial or complete reactions of degeneration to electrical tests,"² *main en griffe*, and double ankle-drop being not uncommon distortions.

ON THE USE OF CERTAIN NEW CHEMICAL TESTS IN THE DIAGNOSIS OF GENERAL PARALYSIS AND TABES.

BY

GEORGE W. ROSS, and

ERNEST JONES,

M.A., M.B. TORONTO,
M.R.C.P. LOND.,
IN CHARGE, DEPARTMENT OF
THERAPEUTIC INOCULATION,
TORONTO GENERAL
HOSPITAL.

M.D., M.R.C.P. LOND.,
DEMONSTRATOR IN PSYCHIATRY,
UNIVERSITY OF TORONTO;
PATHOLOGIST TO TORONTO
HOSPITAL FOR
INSANE.

The diagnosis of general paralysis of the insane is for two reasons a more important matter than the diagnosis of most forms of insanity. On the one hand, thanks to the clinical observations of Pilcz, Kraepelin, and a host of other workers, with the pathological researches of Nissl and Alzheimer, we have a clearer picture and more exact knowledge of the course and nature of the disease than about almost any other psychosis, so that we can foretell what events are likely to occur in it, and take measures to guard against them. On the other hand, the prognosis is more fatal and the lethal termination more rapidly reached than in any other form of insanity, so that it is important to recognize the condition as soon as possible, and to get the patient's affairs arranged on the basis of that knowledge. Although in a pronounced case the clinical picture is one of the sharpest in the whole of medicine, yet in an early or non-typical case the difficulties in diagnosis are often exceedingly great. So much is this the case, that it is found in asylum practice that the majority of the patients are admitted either with an erroneous diagnosis, or else comparatively late in the course of the disease. Hence the additions to our knowledge that of late years have accrued from a study of the cerebrospinal fluid in the disease have been welcome and valuable aids to the practitioner. These newer laboratory methods of course can never replace accurate observation of the well-known physical signs of the condition, any more than Vidal's test has replaced the employment of physical examination in the case of typhoid fever, but a knowledge of them is of the utmost importance when we have to deal with obscure and doubtful cases.

Before detailing some personal researches it will be well to review very briefly present knowledge concerning the cerebrospinal fluid in general paralysis, and this is best done, perhaps, by mentioning the various points in the chronological order of their discovery.

The first step in this connexion, and still one of the most important, was the discovery, made in 1900 by Ravaut, Vidal, and Sicard, that lymphocytosis in the cerebrospinal fluid is one of the most constant accompaniments of both general paralysis and tabes. Many forms of cells are found, the most significant being large mononuclear lymphocytes and plasma cells. When in a non-febrile malady the lymphocytosis is very pronounced, then it may be regarded as practically pathognomonic of general paralysis. The cell increase is greater at the onset of the disease—a fact that obviously enhances its value in diagnosis.

A year later the discovery was made by Achard, Loefer, and Lambry that considerable quantities of proteid are to be found in the cerebro-spinal fluid in general paralysis and, to a less extent, in tabes. As the present paper is chiefly concerned with this question, consideration of it may be conveniently postponed for the moment, and it will suffice here to mention the well-established facts that in normal cerebro-spinal fluid the quantity of proteid is minimal, that in the diseases in question the increase is mainly an increase in globulin, and that this increase is not always parallel with the degree of lymphocytosis, tending on the whole to develop later than this phenomenon.

The next discovery was the startling one made by Wassermann in 1906, that the cerebro-spinal fluid in general paralysis contained substances which, when combined with the syphilitic virus, have the power of inhibiting haemolysis. It will be remembered that in 1900 Bordet demonstrated that in various processes, of which haemolysis may be taken as a type, three bodies are essential components. These are, first, the antigen, or substance that is being destroyed—bacterium, blood cell, etc., as the case may be; secondly, a non-specific substance, or complement, found in all blood serums; and, thirdly, a specific substance, or amoceptor, found only in the serum of an individual that has been previously injected with the corresponding antigen—the amoceptor being thus evoked as a response to the foreign body. It follows that if two of these three bodies are present in a fluid and cytotoxicity does not take place, it must be due to the absence of the third; thus, if the antigen is not dissolved on being added to its corresponding amoceptor, the complement must be missing. In this way we can test for the presence or absence of complement. Now Wassermann found that syphilitic virus obtained from a fetal liver in which spirochaetes had been demonstrated, when in the presence of the cerebro-spinal fluid of a paralytic, made a combination with it and the complement present in any blood serum. This complement was thus taken up or fixed, and was no longer free to cause haemolysis when added to red blood cells and haemolysis in the way just mentioned. For this test he first incubates for an hour the syphilitic liver emulsion with the suspected cerebro-spinal fluid and the complement containing serum of a guinea-pig; he then adds the mixture to an emulsion of washed red blood corpuscles of a sheep and some serum of a rabbit that has been several times injected with sheep's blood. If the blood cells dissolve—that is, if haemolysis or laking takes place—then the complement must have been free to do it, and could not have been fixed by the preliminary incubation. Wassermann maintains that this is due to the absence of any syphilitic antibody or amoceptor in the cerebro-spinal fluid. On the other hand, if laking does not take place, then the complement must have been previously fixed by the combination of the syphilitic antigen from the liver and syphilitic antibody in the cerebro-spinal fluid.

While Wassermann's observations have received the widest confirmation, his interpretation of the phenomenon has met with serious criticism, and is to-day practically discredited. It is quite true that the reaction just described is positive in over 95 per cent. of cases of parasyphilis, and negative in other diseases, so that beyond doubt there is some substance in the cerebro-spinal fluid which when combined with syphilitic virus has the power of fixing complement and thus inhibiting haemolysis. But the nature of this substance is a far more disputable matter. That it is not a specific syphilitic antibody seems to be certain from the observations made, first by Weil and Braun, that it shows the same power of inhibiting haemolysis when combined with other substances than syphilitic virus—for instance, lecithin. It is now known that the place of the syphilitic antigen can be taken by a number of substances, including lecithin, bile salts, brain emulsion, normal liver emulsion, etc.; and Benecke has recently brought evidence to show that the efficacy of the syphilitic liver in Wassermann's experiments is due to the presence in large quantities of a peculiar soap pellicle that surrounds the fat droplets characteristic of that lesion.*

Leaving, however, the theoretic aspect of the question, we have to note that all workers at the subject—notably Plaut, Morgenroth and Stertz, Marie, Levaditi, Yamanouchi, Weil, Eichelberg, and Neubauer—are unanimous as to the high practical value of Wassermann's discovery. It may be said at once that it is the most certain sign of general paralysis we at present possess. Its only disadvantage is the complexity of its application, and before it can be of much value in practice it will have to be considerably simplified.

Two other methods may be briefly mentioned. In 1907 Fornet and Scherschewsky stated that the serum of a luetic patient gives a specific precipitate with the serum of a paralytic. This observation has been received with much scepticism, and Plaut, who is perhaps the most reliable authority on the subject, says that this precipitate is just as common with normal serum. In 1908, Porges and Meier showed that the cerebro-spinal fluid of paralytics causes a heavy precipitate when added to the lecithin emulsion. This is of interest when one remembers the important part played by lecithin in the Wassermann reaction.

The theoretic interest that the increase in globulin has resides in the fact that most authorities agree in attributing to it the origin of the substance active in the Wassermann reaction. The trend of opinion is towards regarding this as resembling choline and nucleo-proteid in being katabolic products produced in the course of the disease. The relation between globulin and the substance that gives the Wassermann reaction becomes therefore a matter of great interest, and the phenomenon of globulin increase receives an accession of both practical and theoretical importance from these considerations.

Now, the experience of the past eight years has amply confirmed the fact of globulin increase in general paralysis and its very great value in diagnosis, and the object of the present communication is to consider two new methods for the precise observation of this increase, together with the results of our experience with these methods. The first of them was described some five months ago by Noguchi of New York; the second has not hitherto been described.

There are, of course, several methods in general use for the separation of globulin from albumen, but all of these leave much to be desired in reliability and delicacy. For the cerebro-spinal fluid the following are those that have been most employed. Guillaumin recommends that the fluid be saturated with magnesium sulphate and then heated; a precipitate indicates the presence of globulin. Nissl, Henkel, Nonne, and Apelt, who have all published extensive monographs on this subject, add to the fluid an equal quantity of a saturated ammonium sulphate solution. Cimbald adds a saturated zinc sulphate solution. In our experience, however, these methods sometimes fail even after twelve hours to give a precipitate with fluids that at once give one in the two tests next to be described.

We shall consider first the technique of these tests and then the results obtained.

Whichever test be applied, it is essential first of all to be sure that no blood or pus has contaminated the fluid to be examined; results are of little value even in cases in which there was a very high lymphocyte count, on account of the secondarily derived globulin. The test may be carried out at any date after the puncture, provided only that the fluid be clear.

The Noguchi reaction consists in the addition of 0.5 c.cm. solution of 10 per cent. butyric acid in normal sodium chloride solution to 0.1 c.cm. of the fluid to be examined, the application of heat, subsequent addition of 0.1 c.cm. of 4 per cent. sodium hydrate solution, with a further application of heat. The test tube should be read within three hours. A distinct opalescence is frequently found to occur even with the normal, but in cases of general paralysis and tabes a characteristic precipitate of a peculiar flocculent character forms. The flocculi tend gradually to fall, so that after twenty-four hours at the latest the bottom of the tube is occupied with a fairly bulky precipitate, whilst the supernatant fluid is clear. In performing this test care must be taken to ensure the absolute purity of the butyric acid. This was evidenced during the experiments by the following occurrence. We had finished the brand of butyric acid obtained from Dr. Makins, of New York,

* This subject was fully discussed by Dr. Mott in the second of the course of lectures on Syphilis of the Nervous System, published in the JOURNAL of February 20th.—Ed. B. M. J.

that had been found to be satisfactory, and on December 7th tried a new brand in 6 cases. To our surprise all of these gave negative results, a finding that was shown, by comparison with some that Dr. Noguchi kindly placed at our disposal, to be due to impure butyric acid.

The second test referred to is as follows: 2 c.cm. of a saturated solution of ammonium sulphate are placed in a test tube, and 1 c.cm. of the cerebro-spinal fluid is gently run on to the surface in the way done in the Heller nitric test for albumen. The formation of a ring at the junction of the two liquids constitutes a positive reaction. The ring is clear-cut, thin, greyish-white, and has the thickness of a thin piece of paper. It should form within three minutes, and within half an hour it may be observed that the surface of the ring shows a delicate mesh appearance resembling a fine cobweb. Indirect illumination must be used, or it may escape detection. For this purpose we have constructed a black-lined box into which the test tube can be inserted and viewed at right angles to an electric bulb which is fixed within the box a few inches away. In applying the test it is essential to see, first, that the ammonium sulphate is pure, so that the solution is neutral and not acid; and, secondly, that the solution is quite saturated, which is best ensured by the use of heat in its manufacture.

We come now to the question of results. Up to the present we have examined only 27 cases, but the paucity of our material is partly compensated for by the uniformity of our findings, which has encouraged us to believe that the tests in question will prove to be of considerable utility.

The Noguchi test was applied in 15 syphilitic cases and 12 non-syphilitic. It was negative in all of the latter except in 1 case of tuberculous meningitis. Among the negative cases were 5 of dementia praecox and 4 of tumor cerebri, conditions which are frequently very difficult to distinguish from general paralysis. Among the 15 syphilitic cases were 12 untreated and 3 treated cases. None of the latter gave a positive reaction, while all of the former did so. The 12 positive cases comprised 3 of tabes, 5 of general paralysis, 1 of tertiary syphilis, and 3 of syphilis of the nervous system. The test was thus positive without exception in all cases of syphilis or parasyphilis that had not had recent treatment, and negative in all other cases examined.

The effect of treatment was shown not only by the non-reaction of the cases under treatment, but also in the disappearance of the reaction seventeen days after initiating treatment in a case that had previously shown a marked positive reaction. It is known that there is an excess of proteid in the cerebro-spinal fluid in no chronic disease of the nervous system apart from syphilis, and that agrees with our findings. In cases of acute infection, on the other hand, there is often an excess of proteid present, whatever be the nature of the infection. This was so, for instance, in the only case of this kind—one of tuberculous meningitis—that we have been able to examine.

The ammonium sulphate ring test was applied in all of the above cases except two of tabes. The results agreed absolutely with those obtained by the Noguchi test, being positive whenever this was positive and negative whenever this was negative, so that the list of cases need not be repeated. The amount of proteid present in normal cerebro-spinal fluid is insufficient to give a ring with ammonium sulphate, though it commonly gives one with pure nitric acid. In general paralysis the amount is increased tenfold, and far exceeds that reached in any other disease, except of course acute meningitis. In the differentiation of general paralysis from syphilis with no nervous manifestation, we would rely not on the mere excess of proteid in the former, for that occurs in both conditions, but upon the striking extent of the excess. This can be roughly estimated with the ammonium sulphate ring test in three ways—by noting first the density of the ring, secondly the time that elapses before its appearance, and thirdly by the dilution with which it appears. The last point has greatly interested us, particularly, however, in connexion with the globulins of the blood serum in syphilis, a matter with which we are not here concerned. Our observations on the point are as yet incomplete, but it would seem that we have in the dilution test a means of readily estimating the amount of globulin present, and therefore the degree of certainty of the

diagnosis. We have several times, for instance, obtained a positive reaction in fifteen minutes after diluting the cerebro-spinal fluid eightfold, a phenomenon that certainly never occurs in the normal.

To sum up, we consider that we have in the Noguchi reaction and in the ammonium sulphate ring test two new methods of considerable value for readily recognizing an excess of globulin in the cerebro-spinal fluid, and thus for determining the presence of some parasyphilitic affection of the nervous system.

TREATMENT OF FACIAL PARALYSIS DUE TO MASTOID DISEASE OR TO THE MASTOID OPERATION.

By FREDK. SYDENHAM, M.D., F.R.C.S.E.,

HONORARY SURGEON, EAR AND THROAT DEPARTMENT, WALSHALL AND DISTRICT HOSPITAL.

In the performance of a series of mastoid operations one is certain sooner or later to have the misfortune to divide the facial nerve during the course of the operation—it has occurred to me three times in over one hundred operations—as it may be found either completely exposed or surrounded by granulations, the cutting of which may completely sever it; or the paralysis may be present before operation, due to destruction of the nerve by the diseased process.

As far as I am aware, the treatment hitherto adopted has been facio-spinal accessory, or facio-hypoglossal anastomosis, the latter being the favourite. I have had two of the latter, and both were successful as far as recovery of the facial muscles was concerned; but the resulting disfiguring scar was objectionable, and the thought occurred to me of trying to join the two ends of the divided nerve in the course of the aqueduct of Fallopius at the site of injury. The following is a short summary of a case which was shown, together with one of my facio-hypoglossal cases, for the purpose of comparison at a meeting of the Stourbridge and District Medical Society on February 18th last:

John P., aged 5, admitted to the Walsall and District Hospital on May 12th, 1908, with chronic middle-ear suppurative and symptoms of cerebral irritation. The mastoid was opened on May 13th, and we found to be extensively diseased, a large part of the outer wall of the lateral sinus being covered with foul granulations. In following out the diseased bone the facial nerve was divided and recognized as such at the time of the operation, and upon recovery from anaesthesia the whole of the side of the face was completely paralysed. The operation was finished in the ordinary way, the wound being sutured up at the back, and the external meatus being thrown into the general cavity. The idea of uniting the severed ends occurred to me, and upon the second day after operation the child was again anaesthetized, the wound at the back reopened, the severed aqueduct exposed, and the proximal and distal ends defined, the distance between them being about from $\frac{1}{2}$ to $\frac{3}{4}$ in. As a scaffolding for the regenerating nerve silkworm gut was used, as it was thought it would better resist the phagocytic action of the tissues, and by its rigidity be more easily introduced into position, and retained there during subsequent dressings. A piece of gut, longer than the interval between the two openings in the bone was used, $\frac{1}{2}$ in. being inserted into each end of the bony canal. The case was dressed daily for a period of one month through the wound at the back, which was not again closed, mainly for convenience in dressing, but also for better drainage. The whole of the area of the anastomosis was carefully covered at each dressing with gutta-percha tissue to prevent any disturbance to the underlying silkworm gut, until the latter became covered with granulations. The battery was used from the first, but no movement of any kind could be produced by the patient for three months, when slight movements of the alae nasi of the affected side were observed upon forced sniffing, the other facial muscles afterwards gradually coming into use. The child was discharged on September 14th, with the wound epidermized and clean, a small fistula remaining behind the ear leading into the operation cavity. The boy has now recovered his normal expression when at rest, and when his facial muscles are thrown into action it is difficult to tell that there has been any facial paralysis at all.

I think I can lay claim to originality in this method of treatment, but I bring it forward for two reasons: first, because of the avoidance of an unsightly scar, which is no small matter in the case of a girl, and which is inevitable in the facio-hypoglossal method; and, secondly, because—as far as my experience of the latter operation goes—of the longer period of time taken for recovery of

the paralysed muscles, which, I think, is due to the fact that for union with the hypoglossal one has to wait until the operated ear has become quite clean and healed, as asepsis is here essential to success, whereas in the method above described repair of the nerve may commence at once.

The operation, also, is no more difficult than the facio-hypoglossal anastomosis; indeed, I believe it to be the easier of the two, for the recognition of the atrophied facial has been to me a matter of considerable trouble, and the difficulty of keeping the operated surface aseptic during the operation is also very great, the anaesthetist being necessarily more or less in the way the whole time the search is being made. The dissection of the hypoglossal nerve, however, is certainly easy, but the greater ease with which the already more or less exposed bony canal in the mastoid—much larger than the atrophied nerve in the substance of the parotid—can be recognized renders this procedure the simpler of the two.

EPIDERMOLYSIS BULLOSA.

THREE CASES: WITH HISTORY OF THE DISEASE IN FOUR GENERATIONS OF THE SAME FAMILY.

By LEONARD B. CANE, M.B., B.C. CANTAB,
M.R.C.S. ENG., L.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE PETERBOROUGH INFIRMARY.

EPIDERMOLYSIS BULLOSA, sometimes described as congenital traumatic pemphigus, though a somewhat uncommon complaint, is one of considerable interest.

It is characterized by an extraordinary vulnerability of the skin, so that on the slightest injury superficial bullae are produced, which are often of considerable size and occasionally haemorrhagic.

The condition is present at or soon after birth, and generally persists in varying degrees of intensity throughout life. It seems to be in nearly every case congenital, and usually, though not always, hereditary.

A case has been reported in which the development of the disease was apparently even antenatal.¹ There were at birth firm adhesions of various parts of the body, which had to be separated by operation, and on the sites of which bullae appeared within a few weeks, and continued to some extent throughout life.

In the *Lancet* of August, 1893, under the heading Congenital Traumatic Bullous Disease, Payne² sums up the characters of the affection thus:

1. Bullae, varying in size, are produced on various parts of the body by friction or any injury, but not otherwise.
2. The bullae are often haemorrhagic.
3. The nails are often affected by similar injuries, becoming deformed or even quite destroyed.
4. There is no disturbance of the general health.
5. The affection is congenital, or at least dates from infancy, and sometimes occurs in several members of the same family; and
6. It is quite unaffected by drugs or other treatment, though its severity seems to depend partly upon the state of the general health.

The etiology is uncertain. Tilbury Fox³ classed his cases with ichthyosis; Kaposi,⁴ Lustgarten,⁵ Norman Walker,⁶ and others with urticaria; and Crocker,⁷ in common perhaps with the majority of the more recent observers, described it as a form of pemphigus.

Various constituents of the skin have by independent observers been found to be altered, deficient, or absent. Engman and Mook,⁸ followed in this country by A. F. Savill⁹ and others, have found the elastic tissue in the papillary and subpapillary regions defective; Elliot¹⁰ an imperfectly developed stratum basale; and Bukovsky¹¹ a loss of continuity of epidermis and corium.

Petrini-Galatz,¹² and others favour a peripheral nervous origin, on the analogy of the changes in tropho-neurotic leprosy; whilst Blumer¹³ compared the affection with haemophilia, pointing out that both diseases are congenital and hereditary, and both due to defective formation of the blood vessels, "dysplasia vasorum," but that in the one bleeding occurs, whereas in the other merely exudation.

The fact that the bullae are always more prominent in warm, moist weather would seem to indicate an "acquired or hereditarily exaggerated irritability of the cutaneous

vascular system." The exudation appears to vary in position, not only in different subjects but in different parts of the body of the same subject.

Another interesting feature fairly constantly reported is the presence of small groups of milia—little yellowish, cyst-like bodies—round the edges of bullae or of scars from previous bullae. In none of my cases was this condition prominent, but detailed accounts, with diverse hypotheses as to their nature, may be found in reports of cases published by Darier,¹⁴ Grouven,¹⁵ Csillag,¹⁶ Petrini-Galatz,¹⁷ Beatty,¹⁸ Scott,¹⁹ and others.

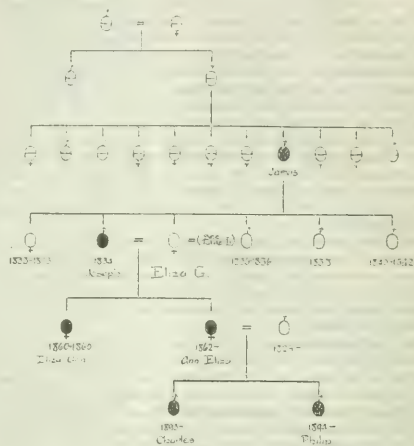

Table 1.—Showing the incidence of epidermolysis bullosa in the family.

The chief interest, perhaps, in the cases under consideration is the evidence of heredity. A definite history has been obtained of blisters lasting more or less throughout life in 6 persons, representing four generations in direct descent, of whom 3 are alive to-day, and form the subject of this paper.

The exact family record can be traced back through nearly two hundred years and embraces six generations, though in neither of the two earlier generations can any information, either positive or negative, as to its incidence be elicited.

Table 2.—Showing that Eliza G. (the youngest of seven children married twice, but did not transmit the disease to her children or grandchildren by her second marriage.

In the "third" generation only one member is definitely known to have suffered from persistent blisters throughout life, and from him this weakness in the skin has been transmitted to the cases now recorded.

In the diagram the genealogy will be seen at a glance, the members definitely affected being denoted by black discs, those definitely free by the clear discs, and those about whom the evidence is doubtful or negative by the crossed discs.

Norman Walker⁶ states that the disease, like some other hereditary complaints, often affects only one sex in a family; but in this instance no such regularity is found,

the disease being twice transmitted from the father, once by the mother, and attacking four males and two females.

Another point of interest is the large size of some of the families, though as will be seen from the dates it is not, as might perhaps be suggested, the late children who were affected; indeed, the order of birth apparently has no influence on the occurrence of the disease.

The three cases are as follows:

CASE I.

Ann Eliza, aged 46, married; husband, aged 79, in fair health, with no history of blisters either in himself or in other members of his family.

The patient is a healthy, active woman, engaged in small secondhand clothes business; previous health and present general condition good.

Skin, except for occasional bullae and at sites of former lesions, is normal in appearance, with no apparent abnormalities in pigment, moisture, thickness, or elasticity.

On the backs of the hands, more especially at the bases of the fingers, are some small bullae filled with clear fluid, alkaline in reaction, and histologically indistinguishable from normal serum. On the feet larger bullae frequently appear, and there are also scars of previous bullae.

She states that when accustomed to wear tightly fitting corsets there were almost constantly present round the waist a number of blisters, some "about as large as a walnut." (Cf. cases recorded by Goldscheider¹⁹ and Wickham Legge.²⁰) They also appeared round her legs as long as she continued to wear garters. (Cf. Valentin's²¹ case and the second case reported by Elliot.¹⁰)

Menstruation.—Just before the menstrual flow, which is regular but always scanty, the bullae were invariably more pronounced, but improved again with the onset of the flow. This interesting fact, which has been noted also by Lesser²² and by Bulkley²³ in America, would appear to indicate that the exudation varies with the blood pressure. She states, also, that since her marriage, at the age of 29, she has been less troubled than before it; and that when pregnant she was less susceptible to their formation. "The blisters went into the child," as she puts it.

CASE II.

Charles, eldest of two sons of Ann Eliza (I), aged 15. General physical condition fairly good, though he says he is "always sleepy," and very easily tired by any exertion. The skin, except for the bullae and scars, appears quite normal in colour, moisture, thickness, and elasticity.

Bullae.—Several large bullae on both feet, especially on the soles and front of ankles. On the right hand there are now three small blisters on the back of the fingers, and one small one on the back of the left hand; but there have previously been many more on both hands.

Scars on sites of former bullae mark the front of both legs and the feet, the distribution being irregular, and not following the course of any particular nerve.

Blisters first appeared fourteen days after birth on the feet, and some have been present continuously since. Never any on the body, except when attacked by scarlet fever and measles; several once on the neck, where the collar chafed.

Nails quite smooth and in appearance normal. Teeth good. General health has been fairly good, though he is not strong and is very subject to "colds." He has never had chilblains or nettle-rash. When attacked by scarlet fever and measles bullae are said to have appeared on his chest, but to have rapidly disappeared—doubtless due to "scratching." Several rather indistinct milia have appeared at edges of one of the scars on his right palm.

The blood I have examined with the following result:

Haemoglobin	...	90.0 per cent.
Red corpuscles	...	4,105,833 per c. mm.
White corpuscles	...	6,800
(= 1 leucocyte to 641 red corpuscles.)		
Colour index	...	1.03
Relative count:		
Polymorphonuclears	...	72.4 per cent. = 4,634 per c. mm.
Eosinophiles	...	2.8 " = 179 "
Basophiles	...	0.8 " = 51 "
Hyalines	...	1.4 " = 93 "
Lymphocytes	...	22.6 " = 1,446 "
	100.0	6,400
Normoblasts	...	nil.
Poikilocytes	...	nil.
Myelocytes	...	nil.

CASE III.

Philip, youngest of the two brothers, aged 14. General physical condition fairly good, quite up to the average of boys in his neighbourhood. As in the other two cases, the skin generally appears normal in colour, moisture, thickness, and elasticity. Bullae of various sizes on both feet, one or two at the front of the ankles being as large as an average walnut. A number of smaller bullae also on both hands, chiefly, though by no means exclusively, on the backs in the neighbourhood of the knuckles.

Bullae first appeared when he was about 12 months old, on the feet, soon after he began to wear shoes; never on the hands until recently, when he began to work as a shoemaker's

apprentice. A number of superficial scars remain, chiefly on the shins and feet, at the sites of old bullae.

Nails.—On the left hand the nails are distinctly ribbed, especially the thumb nail. On the right hand also there are well-marked longitudinal ridges. The edges are somewhat, though not markedly, rough. Toenails rather thick, with rough, irregular edges and transverse ridges.

The Blood.—Bulkley²³ states that "eosinophiles are constantly found in abundance in connexion with certain eruptions of the bullous type, with an elimination of eosinophiles in the contents of the blisters of pemphigus, etc." In neither of these two boys was this condition found, the analysis in this case being as follows:

Haemoglobin	...	90.0 per cent.
Red corpuscles	...	4,960,000 per c. mm.
White corpuscles	...	6,800
(= 1 leucocyte to 729 red corpuscles.)		
Colour index	...	0.91
Relative count:		
Polymorphonuclears	...	78.4 per cent. = 5,331 per c. mm.
Eosinophiles	...	3.6 " = 245 "
Basophiles	...	0.8 " = 54 "
Hyalines	...	1.2 " = 82 "
Lymphocytes	...	16.0 " = 1,068 "
	100.0	6,800
Normoblasts	...	several.
Poikilocytes	...	nil.
Myelocytes	...	nil.

These three cases have also the following points in common:

The mucous membranes are not involved, a condition which Colcott Fox,²⁴ Dühring,²⁵ Blumer,¹⁸ and Tilbury Fox³ alone seem to have noted.

The condition is always worse in warm, moist weather, when the boys are frequently "laid up altogether."

At times there is marked hyperidrosis, especially in the feet. (Cf. Whitehouse,¹⁶ etc.)

The teeth are fairly good, quite up to the average both in number and quality. (Cf. Blumer's¹⁸ and Pernet's²⁷ cases, and those recorded by Dühring,²⁵ Colcott Fox,²⁴ and Galloway,²⁸ in which the teeth were markedly defective.)

The Eyes.—In none of these patients is there any defect in vision. Examination of the fundus revealed in each case a normal optic disc, healthy retinal vessels, and no evidence of exudation into the choroid or of previous choroiditis. Ocular tension was neither increased nor diminished. There is no evidence or history of phlyctenules or of any ocular disturbance.

In the vascular system there is no ascertainable disease of either the heart or blood vessels. The pulse I have examined digitally with care on many occasions, but have failed to find any appreciable difference in pressure either in the periods in which the patients were comparatively free from bullae or during those in which the condition of the skin was at its worst. Possibly with a sphygmometer some increase in pressure might be found to precede or accompany each "relapse."

Repeated examinations of the urine in these patients have revealed no abnormal constituent, nor is there at present any appreciable deposit. The specific gravity when last taken was 1020, 1014, and 1016 respectively, and the reaction acid.

In a paper by Bulkley²⁹ a number of cases is collected which relate to the altered state of the urine in no less than eighteen different cutaneous affections. The results, though not very conclusive, "indicate an impaired metabolism which lies at the bottom of the wrong nutrition of the skin, whereby it readily takes on diseased action from various causes, local and internal."

It is therefore possible that a series of analyses more thorough than those I have been able to make might reveal in these cases some abnormality.

DIAGNOSIS.

The diagnosis of epidermolysis bullosa should present few difficulties though its classification must still remain in doubt.

Crocker⁷ describes the disease as a form of pemphigus, but so long as the true nature of this itself remains open to doubt, there is but little profit in arguments either for or against such inclusion.

The limitation of the bullae to parts exposed to friction or injury, the fact that it but seldom if ever reacts to arsenic, and the many cases in which the general health remains unaffected, have been put forward as arguments against such inclusion; but, on the other hand, the general clinical appearance of the affected parts, the occasional implication of mucous membranes, and those cases in which

the general health has been impaired in consequence of the complaint, are all points in which it strongly resembles pemphigus.

From *urticaria bullosa*, with which it has been sometimes grouped, it presents the following points of distinction: The course is much more chronic, persisting often for months without apparent improvement; the bleb does not develop on a wheal; there is, as a rule, no accompanying itching, nor is its duration appreciably affected by any changes in diet. Walker⁶ states that epidermolysis "is sometimes responsive to treatment for urticaria." I have tried calcium chloride, 10-20 grains t.d., upon one of my cases for a considerable time, with detailed instructions as to diet, the regulation of the bowels, etc., but without the slightest noticeable effect upon the bullae.

From *bullous syphilides* most cases, including those under our consideration, are distinct in that there is no evidence or history of syphilis, either congenital or acquired, nor is the distribution of the bullae that commonly associated with that disease.

Dermatitis herpetiformis resembles it in the frequency of relapses and unsatisfactory response to almost every form of treatment; but the multiformity of lesions and paraesthesiae, which are such a marked feature of that disease, are in epidermolysis completely lacking.

From *leprosy* it is readily diagnosed by the general appearance of the bullae and the absence of either nodules or patches of anaesthesia.

Erythema multiforme, as the name implies, is characterized by the polymorphous nature of the eruption and by the inflammation which usually accompanies it.

Impetigo contagiosa and *varicella bullosa* are, of course, scarcely likely to be mistaken for epidermolysis, since the one is so readily amenable to treatment and the other to spontaneous cure within a definite time.

TREATMENT.

The treatment of epidermolysis bullosa is most unsatisfactory. Sir Malcolm Morris,²⁰ in the latest edition of his textbook, published in October last, states that "the disease appears to be incurable, but much good may be done by protecting patients from deleterious influences and attending carefully to their nutrition." Dr. Adamson,²¹ again, in a book published last year, writes: "Patients affected with this disease are only free from lesions when properly protected."

In my cases the treatment adopted has been to urge upon the patients the importance of cleanliness, and the application at frequent intervals of pieces of lint or linen soaked in some simple solution, such as glycerinum acid. carbol. glyc. ac. bor., or a calamine and lead lotion. The patients themselves are always careful to avoid, as far as possible, any source of irritation or friction.

Internally nothing except an occasional tonic can be said to cause any real improvement; such degree of success as has occasionally been reported to have followed the administration of various drugs having in all probability been due either to improvement in general condition or to climatic changes. It is somewhat remarkable how soon these cases react to slight changes in temperature, the bullae often disappearing almost entirely for several weeks or even months when the weather is cold, and returning again in the summer.

Since the condition in the two brothers is almost identical, I have, when making trial on either of any drug, refrained always from dosing the other, save occasionally with some inert solution to lessen the likelihood of his sharing his brother's medicine.

In almost every instance any improvement or relapse was in the two brothers simultaneous.

Of the remedies for pemphigus in children and young adults, arsenic has for long been considered almost a specific. For three or four weeks Philip was taking liq. sodae arseniatis three or four times daily, beginning with small doses, m. iij, and increasing by 1 minim every other day up to m. xv every four hours. After about ten days, had I not had his brother as "control," I should have probably attributed a beneficial reaction to the drug; but since the improvement appeared in the brother almost simultaneously, it was evident that a colder type of weather must have been a much more potent factor than the arsenic.

For another three weeks Philip was given particular instructions about diet and regularity of his bowels, and was taking calcium chloride gr. xx in solution three times a day, as recommended by Sir A. E. Wright and others for urticaria. The weather during this period was for the most part damp, and the condition of both brothers suffered in consequence, no appreciable difference being detected between their respective conditions.

The treatment which, hypothetically, should promise some degree of success is that recommended by Dr. A. F. Savill at St. John's Hospital for Diseases of the Skin.

The observations of Elliot¹⁰ that "the prime feature in the existence of the process is an acquired or hereditarily exaggerated irritability of the cutaneous vascular system": of Columbin¹² that "the papillae showed oedema and some infiltration, with dilatation of the blood vessels," and other writers, combined with the fact that the complaint is always worse in warm weather, when the capillaries are dilated, led Dr. Savill to direct attention to the improvement of the cutaneous circulation and the toning up of the small blood vessels by means of ergot. Her cases apparently received benefit from the drug, and are recorded in the *Lancet* for July, 1906. For some months, therefore, with occasional intermissions, Philip was taking ext. ergotae liquidum in increasing doses up to m. xx thrice daily. At one time he certainly showed some signs of improvement, but the occurrence of relapses was not prevented, nor did the improvement after patient trial seem to warrant the continued administration of the drug.

Under none of these remedies was the improvement more marked than that due to a short tonic treatment with syr. ferri phosph. co. or syr. hypophosph. co.

CONCLUSION.

These three cases, with history of three more in the same family, are interesting as showing the hereditary nature and intractability of the disease. They throw no fresh light upon the etiology of the complaint; but the brief review given of some of the literature will serve to indicate the diversity of views that have been put forward. Anyone sufficiently interested in the subject will find in the *British Journal of Dermatology* for August, 1897, a complete summary of all recorded cases up to that date, to which further additions will be found in the article by Dr. Agnes F. Savill in the *Lancet* of July 14th, 1906, and in an exhaustive article on The Inheritance of Certain Human Abnormalities, by Dr. A. M. Gossage, in the *Quarterly Journal of Medicine*,²² l. iii (April, 1908).

THERE are at present 161 women acting as skilled assistants in scientific laboratories in Germany. Most of them are employed on microscopic, bacteriological, "serological," and histological work; some are engaged in Roentgen-ray and photographic work. The number of institutes and hospitals in which the women assistants are working is about 125. A registry office has recently been established in Berlin for women qualified to act as laboratory assistants. There is also an institute in which courses of instruction extending over four to six months are given in Roentgen-ray, photography, and histological technique.

SPIROCHAETA PALLIDA:

METHODS OF EXAMINATION AND DETECTION,
ESPECIALLY BY MEANS OF THE DARK-
GROUND ILLUMINATION.

By ALFRED C. COLES, M.D., D.Sc., F.R.S.Ed.,
M.R.C.P.LOND.,
BOURNEMOUTH.

Now that it is very generally conceded that the *Spirochaeta pallida* is the cause of syphilis, its recognition, especially in the early stages of the disease, is a matter of considerable diagnostic importance.

I have endeavoured to describe briefly the method of taking the material for examination, the most approved methods of staining, and the method of examining the living organism by means of the dark-ground illumination.

I. TAKING THE MATERIAL.

Although the *Spirochaeta pallida* has been found in almost all forms and stages of syphilis, including even the gumma, the most usually selected lesions for examination purposes are:

- (a) The primary sore, either in its unbroken or papular stage or in the usual form, the ulcerative chancre.
- (b) Condylomata and mucous patches, which are so highly infectious, and in which the spirochaetes occur probably in the largest number.
- (c) The indurated glands.
- (d) The various forms of eruptive lesions, especially the papular and vesicular forms, more rarely in the roseola.

From the Primary Papule.

The surface of an unbroken papule should be thoroughly cleansed, and then gently rubbed or scratched with a scalpel. After a few seconds an exudation of a clear or slightly blood-stained fluid appears. Films or cover-glass preparations are made from this. The more blood present in this serous exudation the more difficult will it be to recognize the specific organism, and in these cases in which the rubbing has produced bleeding, it is well to remove the blood, and wait till the bleeding has ceased, before attempting to take the serum.

In the case of the ordinary specific ulcer it is important to realize that the spirochaetes are found in the deeper parts of the wound, and that the superficial layer consists of all kinds of bacteria, and contains the *Spirochaeta refringens* in large numbers, but very few of the *Spirochaeta pallida*. In a preparation made from the surface secretion of a sore, very great difficulty will be experienced in finding *Spirochaeta pallida* and also in distinguishing other non-pathogenic spirochaetes, which are present there in large numbers, from the genuine spirochaete, which may have undergone some degenerative changes. The non-success of many bacteriologists, in the early days after Schaudinn's discovery, was due very largely to the improper taking of the material.

The surface of a chancre should be thoroughly cleansed with water or saline solution, and then rather firmly rubbed with a little cotton-wool or gently scraped with a knife, needle, or sharp spoon, avoiding bleeding. The few drops of blood which first appear should be removed, and then, after waiting a few seconds, a quantity of clear or slightly blood-stained serum exudes. This may be somewhat encouraged by gently massaging the sclerosis. Films should then be made from this serum, either on slides or cover-glasses which have been very thoroughly cleaned. The slides should be slightly warmed first, so that the almost invisible film dries at once. Schaudinn found that, by exposing the slides to fumes of osmic acid for a few seconds before and after spreading the film, the spirochaetes were killed and fixed in a somewhat more natural position. Too long exposure of the still moist film to osmic fumes diminishes the staining properties.

Cover-glass preparations of the serum for the examination of the living organisms should be made on very thin and clean slides. Films made from the serum, "Reizserum, or serum of irritation," as Hoffmann terms it, generally contain large numbers of *Spirochaeta pallida*, few red blood corpuscles, and very little or no cellular

débris. There may be a little difficulty in focussing such thin films, but the presence of a few red corpuscles assists, and in stained preparations the spirochaetes, if present, are easily found. According to Hoffmann, films made from scrapings (*Geshabe*) contain the largest number of spirochaetes.

Some workers excise a small piece of the tissue, and rub this up with a little distilled water, and make films and cover-glass preparations from a drop of this fluid.

Condylomata and Mucous Patches.

Material suitable for examination is obtained in much the same way as from the primary sore. The serum which exudes after rubbing and scraping the surface of a chancre or condyloma may be collected in capillary tubes or blood capsules, the ends being subsequently sealed in the flame. Films and fresh cover-glass preparations may be made from this afterwards.

The Indurated Glands.

The *Spirochaeta pallida* may also be found in the nearest lymphatic glands, commonly those of the groin when the primary sore is situated on the genital organs.

Preiss,¹ who has been able to demonstrate the *Spirochaeta pallida* in nearly 100 per cent. of cases of syphilis in the secondary stage, says that gland puncture should be used in all cases in which the examination of the serum from an ulcer proves negative. This is likely to be the case if the ulcer is partially or completely healed, if it has been treated with caustics, or if it is disintegrated. He has never failed to find the specific organism during the period between the first typical hardening of the glands and the first eruption—six to ten weeks.

The skin over the gland is washed with an antiseptic, shaved, and then rubbed with ether. A syringe with a needle a little larger than that of an ordinary hypodermic is plunged obliquely into the long axis of the gland, which is firmly fixed with the left hand. That the needle is actually in the gland can be ascertained by moving it about, when the gland will simultaneously be felt to move. Whilst the piston is being withdrawn, the whole gland is massaged or squeezed with the left hand. In this way a few drops, probably only enough to fill the needle, are withdrawn. Cover-glass and film preparations are then made from this blood-stained fluid, and examined in the fresh and stained condition.

Syphilitic Eruptions.

The roseola presents the greatest difficulty. Mere pricking the spot and examining the blood affords very little chance of finding the organism. It is much better to scrape the surface gently, and, avoiding bleeding as much as possible, obtain a little clear or blood-stained lymph. Rosenberger, in order to avoid bleeding, pinches up the skin in a pair of forceps until it is pale, and then incises, and aspirates one or two drops of serum. Sometimes blisters are applied over the surface, and the contents of the resulting bulla examined.

In vesicular or pustular forms of eruption the serum or pus is aspirated in capillary tubes or films made directly from the fluid. Better results are, however, obtained by opening the vesicle, removing the contents, and gently scraping the base of the exposed lesion.

II. METHOD OF EXAMINING THE MATERIAL.

The material containing the *Spirochaeta pallida* may be examined by means of dry-stained films or in the living condition in cover-glass preparations.

Staining.

Films may be made either on cover-glasses or on slides, but owing to the nature of the staining reagents they must be scrupulously clean. It has been very generally believed that the *Spirochaeta pallida* was a very difficult organism to stain, that it required special stains, and that the staining process should be extended over a long period. Many of the early failures were attributed to the staining, whereas in some cases, at least, it was the method of taking the material which accounted for the absence of the organisms. It is now known that the spirochaete can be stained by many of the ordinary aniline dyes besides Giemsa's modification of Romanowsky's stain. A. Ehrlich

and Lenartowitz² find that the *Spirochaeta pallida* stains in:

- Ziehl-Neelsen and carbol-gentian-violet, in from half a minute to two minutes.
Carbol-methylene blue and carbol-dahlia, in from five to ten minutes.
Loeffler's methylene-blue and carbol-thionin, in from twenty-five to thirty minutes.
In saturated aqueous solution of Bismark brown and vesuvium and safranin, in one hour or more.

At the present time Giemsa's stain or some other modification of the Romanowsky stain is almost universally used, partly because it stains the organism better than most others, and partly because it imparts to the *Spirochaeta pallida* a more or less distinctive, but by no means absolutely characteristic, tint. Almost all the other spirochaetes are stained bluish with this stain, whilst the *Spirochaeta pallida* takes a reddish colour.

I have experimented with most of the stains recommended from time to time, especially Giemsa's, Leishman's, and Wright's, and find that all to some extent, depending on the duration of the staining and probably the cleanliness of the slides, tend either to cause a granular deposit, or stain the background of the preparation. Preferably I use Giemsa's or Leishman's stain, and on the whole I am inclined to agree with Leishman, who finds that his stain whilst staining the organisms well does not give as much deposit as the first named.

Leishman's Stain.

This can be bought ready prepared, or can be made by rubbing up in a mortar 0.15 gram of the powder with 100 c.cm. of Merck's analytically pure methylic alcohol. Burroughs, Wellcome have placed on the market a solid of Leishman's stain which gives excellent results. This stain can be used in two ways:

1. A few drops of the stain is poured over the air-dried film and allowed to act for about thirty seconds. At the end of that time double the amount of distilled water is added drop by drop, and the slide gently tilted, in order to mix the two solutions. The preparation is then left to stain for about twenty minutes, when it is quickly washed in distilled water, equally quickly dried in the air, but not by heat, and mounted in Canada balsam, or examined in oil.

2. Method.—Here the films are not fixed. One part of Leishman's stain is mixed with two parts of distilled water in a watch-glass, and this mixture is gently poured over the film, and allowed to stain for twenty-five minutes. After which the preparation is gently washed, dried, and mounted.

According to Leishman³ the advantages of the second method are greater freedom from debris, easier detection of the spirochaete, and the spirochaetes appear more numerous than in the fixed films, owing to their being more deeply stained.

I find that a method intermediate between the first and second gives the best result on freshly-made films.

The duration of staining may in either of the above methods be increased, but there is more risk of the background becoming coloured, or a granular deposit taking place. A very good plan is to stain the films for about fifteen to twenty minutes, then roughly but quickly wash, and stain for another fifteen to twenty minutes.

Prolonged staining is, in my experience, attended with a risk of a granular deposit, or a flocculent scum, which settles on the surface of the film and slide. In order to obviate this I have tried staining the slides in wide-mouthed bottles or tubes, but I do not think this is as successful as the following simple plan:

The Leishman stain is poured on the film, and after a few seconds—say ten—double the quantity of distilled water is added, and then the diluted stain is poured rapidly on to the surface of a slightly curved piece of glass, and the slides laid, inside downwards, on the stain. In this way any precipitate in the stain falls on the sheet of curved glass.

Giemsa's Stain.

This should be bought ready prepared from Grubler or from the agents—for example, Baker, 244, High Holborn.

For use the stain is prepared as follows: To 1 c.cm. of distilled water a few drops of 1 in 1,000 solution of sodic carb. are added, and then 1 drop of Giemsa's stain; mix. The air-dried films are fixed for five to ten minutes in methylic alcohol, or for one to five minutes in methylic alcohol, and then the above solution of stain is poured on and allowed to act for one hour. The preparations are then rapidly washed in distilled water, quickly dried, and mounted in Canada balsam or simply examined in oil.

Film preparations can also be stained without previous fixation, as in the second method of Leishman; the only point to attend to is to pour the staining solution on gently and very carefully wash, or otherwise the unfixed film will be washed off. Burroughs, Wellcome, and Co. have made "solids" of eosin-azur for the Giemsa stain, and as these are dissolved merely in

pure methylic alcohol the films need not be previously fixed. These give excellent results. The method and duration of staining are precisely the same as that mentioned for using Leishman's stain.

With all these staining methods there is a little compromise to be made, as the longer the duration of staining, the darker the organism and the thicker it appears, but the greater the tendency to a deposit.

THE EXAMINATION OF THE SPIROCHAETA PALLIDA IN THE LIVING CONDITION.

Hoffmann⁴ says that for the expert endowed with keen vision the easiest and most rapid method of detecting the *Spirochaeta pallida* is to examine it in its living condition. For this purpose he considers a good apochromatic $\frac{1}{2}$ in. objective, with compensating ocular 6 and 12, indispensable. He advises the use of cover-glass instead of hanging-drop preparations, which are rung round with vaseline to prevent evaporation. These are made from the serum alone or the serum diluted with normal saline solution, in which he found the spirochaetes still living for a week. Hoffmann states that Reuter could not see the living *Sp. pallida* with an ordinary Zeiss achromatic $\frac{1}{2}$ in. objective, but with an apochromatic Zeiss $\frac{1}{2}$ it was plainly visible.

My experience with regard to the visibility of the *Spirochaeta pallida* in the living condition in cover-glass preparations of the serum is rather interesting. Working with a magnificent $\frac{1}{2}$ in. achromatic objective of Leitz of N.A. 1.30, and also with Swift's $\frac{1}{2}$ in. apochromatic objectives of N.A. 1.40, and compensating oculars 6, 8 and 18, combined with an oil-immersion condenser of N.A. 1.40, using critical image and working in a dark room, I can say that I have seen three or four living spirochaetes after hours of search under these favourable conditions.

I have placed a freshly made cover-glass preparation on the microscope, and with a Zeiss $\frac{1}{2}$ apochromatic objective of N.A. 0.65 and compensating ocular 18, with the new dark-ground condenser of Leitz and with a Nernst lamp, I have found a field containing fifteen to twenty actively moving *Spirochaeta pallida*. Without moving the slide in the slightest, I have substituted the ordinary condenser, both oil-immersion and dry, have turned on the $\frac{1}{2}$ in. objective, and replaced the Nernst lamp by a paraffin lamp, and have been totally unable to see one spirochaete in the selfsame field, even after a considerable time.

Further, I have returned to the dark-ground method, and, having found a long or specially well-marked spirochaete, I have noted its exact position as regards, say, a red blood corpuscle. Retaining the slide in that position, I have replaced the existing apparatus by the $\frac{1}{2}$ in. objective, with the ordinary condenser, and have seldom, even after prolonged examination, seen that spirochaete.

In other words, I find that the *Spirochaeta pallida* is, under the most favourable condition, almost invisible, even when known to be present, when examined by $\frac{1}{2}$ in. objective with ordinary transmitted illumination. This does not imply that the organism is beyond the range of visibility owing to its small size, but that it is practically invisible owing to its very slight refractive index.

Examination by means of Dark-ground Illumination.

By means of the new dark-ground condensers, however, it is now possible not only to see, but to see easily, many organisms with comparatively low powers.

Such condensers, made by Reichert, Zeiss, Leitz, Beck, and others, vary somewhat in their principle and construction. I have tried all of them, and prefer that made by Leitz.

A brilliant source of illumination is absolutely essential in using any of these dark-ground condensers. Briefly, my outfit consists of the following:

1. A Leitz dark-ground illuminator.
2. Nernst $\frac{1}{2}$ ampere lamp.
3. A Nelson's splanatic bull's-eye condenser. Probably the new small air lamp recently introduced by Leitz would be better. It has a bull's-eye condenser fitted with it.
4. Slides of a given thickness (1 mm.), and cover-glasses preferably of known thickness.

Full directions are supplied with any one maker's condenser, and a short but good account is also given in Spitta's *Microscopy*, second edition, the best treatise on the microscope published in the English language.

The dark-ground condenser having been placed in the sub-stage and centred, the light from the Nernst lamp concentrated

by the bull's-eye thrown on the mirror, the slide holding the fresh serum preparation is placed on the stage and is oiled to the condenser.

I use Zeiss apochromatic $\frac{1}{2}$ objective with compensating ocular No. 18, which gives approximately a magnification of 500 diameters. Least $\frac{1}{2}$ in. oil-immersion objective may be used with his dark-ground condenser, provided its N.A. is cut down to 0.9 by a special stop which he supplies. This I find answers admirably.

The use of an immersion $\frac{1}{2}$ objective cut down by a stop to a N.A. of 0.9 has the following advantages: (1) Increased magnification, (2) the cover-glasses need not be of specified thickness, (3) the image is considerably brighter, and (4) the resolution is greatly increased.

It is not essential to use apochromatic objectives for this method of examination, an ordinary $\frac{1}{2}$ with deep eyepieces is suitable, but the achromatic dry lenses do not give as good a view as the apochromatics.

Spirochaeta pallida examined by this method appear as shining silver-like threads with corkscrew turns lying on a black or blackish background. They will be seen to possess three movements—namely, rotation about the longitudinal axis, forward and backward gliding motion, and flexion of the whole body.

Of these, the last-named is the most easily seen and the most characteristic. It is a slow bending motion. The rotation about a longitudinal axis is to be seen with the stopped $\frac{1}{2}$ in. objective, and gives the impression of a screw being turned. The forward and backward movement is—at least when examined in its natural fluid, the serum—very slight indeed. If there be streaming movement of the serum, which is often induced by evaporation at the margin of the cover-glass, the spirochaetes will be carried rapidly across the field, and it may soon be out of sight.

The actual movement of locomotion is under ordinary condition so slight that I should hardly expect to find that the organism had moved much from the exact spot at which it had been seen an hour previously. This is very different from what is met with in the other spirochaetes—for example, *Spirochaeta refringens* or *Spirochaeta balantidis*.

Eiter⁵ gives the following excellent description of the *Spirochaeta balantidis*, and I may add that, in the absence of a case of that disease, one can see all the movements he describes in the *Spirochaeta buccalis* by simply making a cover-glass preparation from the scrapings of one's teeth.

When seen by means of the dark-field illumination this spirochaete appears pale yellow to deep orange red, as compared with the delicate white of the *pallida*. The body is fatter, the windings are longer and flatter, and it is much more energetic than the *pallida*. It moves rapidly in jerks backwards and forwards, frequently crossing the whole field with one impetus. At times it moves with a wave-like progression, either like the movements of a snake or those of a caterpillar. The wave-like movement, which does not cause the spirochaete to move in its entirety, is seen in this form as in the *pallida*. Besides, one sees screw-like movements, by which the body progresses by means of a rotation on its long axis.

The *pallida*, on the other hand, moves in three ways: (1) Rotation around the long axis, (2) by bending its body, and (3) by jerks backwards and forwards. It seems, however, that the *pallida* do not move widely or energetically, and when a *pallida* spirochaete is seen crossing the field, it is always being carried in the current of the fluid medium.

So far as my experience goes no other organism could be easily confused with the *Spirochaeta pallida* when seen by dark-ground illumination, except the *Spirochaeta dentium*. This organism, which is found in small numbers in the tartar of the teeth, resembles the *Spirochaeta pallida* in its white silvery colour, its numerous turns and its movements, but it is much shorter, measuring on an average 5 to 8 μ with 6 to 16 windings.

As to the duration of the life of the *Spirochaeta pallida*, I found that in cover-glass preparations made from the serum taken from a primary sore, some of the spirochaetes were recognizable at the end of thirty-one days, and that they still possessed their characteristic bending or slight swaying movement.

Examination of Stained Specimens.

The *Spirochaeta pallida* in stained preparations is seen to consist of very fine spiral threads which measure on an average 6 to 15 μ long, although some reach 16 to 24 μ , and about $\frac{1}{2}$ μ wide.

It possesses a number of extremely regular, deep, and closely approximated spirals. They vary in number from

6 to 22 μ , and the width of the curves, or the distance from the summit of one convexity to that of the next, is very constant—that is, about 1 to 1.2 μ . This is a very important characteristic, and can easily be ascertained by measuring the length of the organism, and dividing that figure by the number of curves. If an eyepiece micrometer is not at hand, the curves may be measured with tolerable accuracy, as pointed out by Leishman, by comparing a spirochaete with a red blood corpuscle of which the average diameter is 7.5 μ , when it will be found that a spirochaete in this distance will have from six to seven turns.

Both ends of the organism terminate, as a rule, in a very fine point, or, according to Schaudinn, in a fine flagellum, which I have, however, not seen.

The whole organism looks, as Schaudinn described it, as if it were a spiral turned out of a lathe. This typical spiral form is seen not only when the organism is in motion, but also when at rest, whilst all other analogous spirochaetes of this type show the spirals only when they are actively moving; when they are at rest they become nearly straight, or have very long flattened-out undulations. Schaudinn points out that there is only one spirochaete, the *Spirochaeta dentium*, of which we have spoken before, which has smaller fixed spiral arrangement.

The great length of the sharply-pointed threads in proportion to its remarkable thinness, the depth, steepness, and regularity of its corkscrew windings, the slight variations in form, the relatively great elasticity, with slight deformation of the spirals, the slight refractiveness, the method of movement in the living condition, and finally the reddish tint that it stains by Giemsa's stain, are the diagnostic features (Hoffmann).

Most of the other spirochaetes are distinguished from *Spirochaeta pallida* by the greater thickness in proportion to their length, their markedly refractile character, the blunt ends, the much more active movements—eel-like—with greater change of position. The spirals are much flatter, more irregular, the organism more pliable, and therefore their form is more changeable, and when stained by Giemsa have a bluish-red tint.

The number of *Spirochaeta pallida* found in a cover-glass or film preparation taken from a primary sore varies enormously. In fresh films, examined with $\frac{1}{2}$ objective and 18 eyepiece, I have seen as many as ten to fifteen on one field; and in stained films made from the same preparation, and examined with $\frac{1}{2}$ objective and No. 2 ocular, I have found three, four, or even six organisms in one field, but this, as far as my experience goes, is very exceptional. Hoffmann says that the spirochaetes vary considerably in number even in the same lesion. Quite recently I had a good example of this in a primary sore from which I took two films made from the serum obtained by scraping the sore with a sharp spoon. In these films, taken at 10 a.m., I found very numerous *Spirochaeta pallida*; but when I took some twenty-four films (dry and moist preparations) from the same sore, from serum obtained by briskly rubbing the surface of the lesion, I found exceedingly few organisms, although these were taken only ten hours later in the day and the wound had not been touched in the interval. Hoffmann mentions, as an example of the unequal distribution of the specific organisms, a case with two primary sores on the abdominal wall, lying quite near one another; in the one he found the spirochaetes very numerous, in the other none, although the chancres were clinically indistinguishable.

EFFECT OF TREATMENT.

As to the effect of treatment on the spirochaetes, mercury given internally and mercurial wash or iodoforn ointment applied externally is undoubtedly associated with a gradual diminution in the number or an actual disappearance of the spirochaetes, and this takes place more rapidly in some cases than in others.

The following is an example of the rapid disappearance of the organisms in a case recently under my care:

February 5th. Case first seen; typical large indurated sore with enlarged inguinal glands. *Spirochaeta pallida* very numerous both in fresh films examined by dark-ground illumination, and in stained preparations. Gave hydrarg. a creta internally, and locally iodoforn.

February 12th. Sore beginning to heal; spirochaetes markedly diminished.

February 20th. Sore not healed. Spirochaetes only found with difficulty.

March 2nd. Sore not healed. No spirochaetes found in fresh or stained films. Gland juice obtained by aspiration of the lymphatic gland—entirely negative.

CONCLUSIONS.

1. The easiest, quickest, and by far the most certain method of detecting the *Spirochaeta pallida* is by the examination of cover-glass preparations made from the serum, by means of dark-ground illumination.

2. That the most important part of the whole procedure is the correct taking of the material, whether for fresh or dry film preparations.

3. That it is not essential to examine fresh films (which have been rung round with vaseline) at once, as the organism may be recognized some days later.

4. That the serum of irritation may be conveniently taken in capillary tubes or blood capsules, provided the ends are sealed, and cover-glass preparations made from it may be examined at leisure.

5. That whilst the finding of the *Spirochaeta pallida* indicates, as far as our knowledge goes at present, syphilis, a negative examination is of little value, at most it only justifies a suspicion that the disease is not present.

P.S.—I should add that the *Spirochaeta pallida* in stained preparations somewhat fade sooner or later. This fading of aniline stained preparations, blood or other films, when mounted in Canada balsam is a source of great disappointment. I have tried Gruber's neutral balsam, but with only moderate success. I should be delighted to hear of a mounting medium in which aniline stained preparations were permanent.

MEDICAL, SURGICAL, OBSTETRICAL.

THE ETIOLOGY OF BERI-BERI.

I HAVE read with interest the report in the JOURNAL of April 24th, p. 1007, of the meeting of the Society of Tropical Medicine and Hygiene at which the etiology of beri-beri was discussed, and observe that it was suggested that after the husk was removed from rice an epiphyte developed outside the grain and generated a nerve toxin. In the JOURNAL of November 28th last there is an interesting note by Dr. Saldanha, in which he says that there is a fungoid disease of rice, the active principle of which he calls "arsin," and to which he attributes the disease. He points out that the Chinese cook rice with the dust on it as it comes from the sack and thus consume the arsin. It is perhaps worthy, therefore, to note that in Korea, where I have been for five years, beri-beri does not seem to be common, although rice is as exclusively the diet of the people as in China, and Dr. Saldanha's theory suggests a reason for this immunity. The Koreans are extremely particular about washing rice before cooking it, and though they often drink the water in which it is boiled, as do the Chinese, they very carefully mix it with several separate quantities of water, each of which is poured away before the cooking commences, the process lasting five to ten minutes. This serves to remove all dust and the arsin which Dr. Saldanha tells us it contains, and may account for the fact that I have not seen a single undoubted case of the disease in five years.—I am, etc.,

HUGH H. WEIR.

SULPHURIC ACID IN CELLULITIS, BRONCHIECTASIS, AND CONSUMPTION.

AS we have received inquiries from different parts of the country as to whether we have used the treatment mentioned in our note in the BRITISH MEDICAL JOURNAL, p. 407, August 15th, 1908, on the use of acid. sulph. dil. in large doses (20 to 30 minims well diluted every four hours), for pathological conditions other than cases of furuncu-

losis, we may mention that we have used it with equal success in cases of acute cellulitis arising from an infected skin abrasion caused by bones from *high game* and also with great benefit in checking the profuse expectoration in cases of bronchiectasis, and in the sweating and expectoration in cases of pulmonary tuberculosis.

In a case of a suppurating dermoid which we are now treating in this way the result so far is not so successful as in the above-mentioned conditions, no doubt because the infected area is encysted.

ACUTE ADDISON'S DISEASE.

H. Y., female, aged 33, was said to have suffered from chronic bladder and kidney disease for five years. When first seen on March 8th, 1909, she complained of increasing weakness and loss of appetite of three weeks' duration. She was thin and ill nourished, and the urine, of which she passed 2½ pints in twenty-four hours, was alkaline, and contained a considerable amount of mucus. Both kidneys were easily palpable, but not tender. Beyond this there were no physical abnormalities, and there was no pain and tenderness in the abdomen.

On the next day she commenced to vomit after any food, and even without food. Day by day she grew weaker, and the vomiting continued until March 16th, when she was given 5 grains of suprarenal extract every four hours. For twenty-four hours she became brighter, and the vomiting ceased, but soon the symptoms resumed their course, and on March 24th she died. During the last few days she lost the power of swallowing, and was fed by a nasal tube. Enuresis also set in. Consciousness was retained until the moment of death.

Permission for a post-mortem examination was readily given. The kidneys were in a state of advanced tuberculosis, very large, and riddled with cavities containing pus and caseous material. The capsules of the kidneys were studded with tubercles. The bladder was thick-walled, and there were numerous ulcers. The suprarenal glands were covered and permeated by milky tubercles. The remaining organs were not affected.

The diagnosis during life seemed to lie between hysterical vomiting and Addison's disease, especially as there was a definite history of former nervous attacks of a melancholic type, accompanied by difficulty in feeding. The marked though transient effect of the extract of suprarenal gland was of great interest.

TREATMENT OF RHEUMATOID ARTHRITIS BY CATAPHORESIS.

FROM the memorandum by Dr. J. Curtis Webb in the JOURNAL of April 17th, p. 352, I gather that in the treatment of rheumatoid arthritis by cataphoresis he is in the habit of applying the positive and negative electrodes moistened with the same solution on either side of the joint affected. I venture to suggest that he will get better results if one electrode and one solution be applied to the particular joint, while the other electrode is placed elsewhere on the body.

My method is to surround the joint affected with a large pad of lint of ten layers in thickness soaked in the particular solution, and to place round this pad a metal gauze electrode tightly bound to the limb and connected with the negative pole. By this means salicylic acid is introduced when a solution of sodium salicylate is employed; iodine when potassium iodide is used, and chlorine when sodium chloride is applied. The positive electrode, laid on a large pad of lint soaked in an ordinary salt solution, may be placed on another part of the body. I can speak from personal experience of the value of this treatment in reducing swelling, alleviating pain, and lessening rigidity of the tendons in cases of rheumatoid arthritis.

Glasgow.

W. F. SOMERVILLE, M.D.

UNDER the will of the late Mr. Alfred Midgley of Buxton, a Manchester merchant, the Huddersfield and Manchester Infirmarys each receive a bequest of £1,000.

SECTION OF MEDICINE.

Tuesday, April 27th, 1909.

Dr. T. H. GREEN, Vice-President, in the chair.
Blood Pressure.

DR. O. K. WILLIAMSON read a paper on the influence of the vessel wall on (so-called) arterial blood-pressure readings. Observations by the method of circular compression were made on the leg and arm of each patient in 21 cases of high arterial blood pressure. In all of these cases in which the arteries of the leg and foot could be felt these were found to be abnormally resistant, and more so than those of the upper extremity; and in nearly all the cases there was also marked thickening in the arteries of the upper extremity. Ten cases of normal or low blood pressure, in which the arteries presented no clinical evidence of disease, were investigated in the same manner so as to afford a basis of comparison. The observations were made on the calf and arm, the patient observed being recumbent, and the part of the limb on which the observation was made at the level of the heart. Oliver's compressed-air haemomanometer was used with his 12 cm. armlet. These observations showed that the resistance due to the arterial wall might markedly influence the readings for the following reasons:

1. In the high blood-pressure cases the leg systolic readings were in nearly all cases markedly higher than the corresponding arm readings (average difference 32 mm.), and the cases of highest blood pressure yielded distinctly greater differences than the cases of somewhat lower blood pressure. On the other hand, the leg diastolic readings in these cases were, on the average, practically identical with the arm diastolic readings (average difference less than 2 mm. Hg.).

2. In the case of normal or low blood pressure the systolic arm and leg readings were found, on the average, to be identical (average difference less than 2 mm. Hg.).

3. Inasmuch as the blood pressure in the leg could not be higher than that in the arm (either limb being at the level of the heart), and seeing that the influence of the tissues superficial to the artery might (when a sufficiently wide armlet was used) be neglected, it necessarily followed that the difference between the arm and leg readings could only be due to resistance of the arterial wall.

4. The conclusion that the abnormal condition of the arterial wall was a direct result of the increased blood pressure would seem to be inevitable, for the only obvious difference between the conditions to which the arteries of the legs and those to which the arteries of the arms were exposed in daily life was that, owing to the action of gravity, the former were subjected to greater hydrostatic pressure from a higher column of blood than were the latter.

Dr. T. H. GREEN favoured the cultivation of unaided clinical observation in addition to instrumental methods.

Dr. W. P. HERRINGHAM had been lately experimenting with arteries removed and kept for three days in a solution of sodium fluoride and found that they, in many instances, gave high readings that were apparently due to the arterial wall. Also that in the same patient the leg arteries gave much higher readings than those of the arm. Also differences observed during life between the readings of the arm and leg were confirmed in the arteries after death. Dr. T. D. SAVILL referred to the greater change in the leg arteries of old people as compared with those of the arm, but thought the vital factor an all-important one. Dr. LEONARD HILL raised the question whether the differences between the arm and leg readings might not be due to error in instrumentation or the influence of muscular contraction. The readings in arm and leg should be taken simultaneously, and with the muscles relaxed, to be dependable. Dr. C. O. HAWTHORNE emphasized the variability of the strength of the cardiac systoles in producing variation in readings and the importance of comparing the blood-pressure reading with sphygmograms. Dr. WILLIAMSON replied.

CLINICAL SECTION.

Friday, April 30th, 1909.

A. E. GARROD, M.D., F.R.C.P., in the Chair.

Mongolian Imbeciles.

CASES of Mongolian imbecility were shown to the number of 14: 3 by Dr. G. A. SUTHERLAND, 4 by Dr. POYNTON, 2 by Dr. LANGMEAD, 2 by Dr. GUTHRIE, and 3 by Dr.

MORLEY FLETCHER. Dr. SUTHERLAND'S cases were aged 5½, 6, and 4 years respectively. In regard to the thyroid treatment of these cases he said that if a patient improved under that treatment it was probably not an instance of Mongolism. To deal successfully with this disease it was necessary to know the cause. In the majority of patients suffering from this malady death occurred in early life. In Dr. POYNTON'S cases thyroid treatment had been fully tried, and he said that the object of showing the cases was to raise the point as to the value, if any, of thyroid treatment in the condition of Mongolian deficiency. The cases were in themselves of the usual type, the oldest being of a comparatively mild degree. They were not related to one another. Twelve cases had been treated for prolonged periods with thyroid, but the results had not been encouraging. The poor circulation and severe chilblains were somewhat improved by this remedy, and it would appear that these cases were rather brighter and more responsive after commencing the treatment. There did not seem to be any specific action on the underlying constitutional deficiency. In his experience, considerable doses of thyroid soon induced in Mongols signs of excitement and disturbance of health as a direct result, and for that reason small doses only had been given for prolonged periods, such, for example, as 1 grain of the powdered gland twice a day for a child aged 3 years. In this series of cases some had been first-born, some last born, and others in the middle of a family. Some mothers had been young, some old, some neither young nor old. Dr. LANGMEAD pointed out that in one of his cases there was congenital morbus cordis, as evidenced by a loud systolic bruit, and an accessory auricle on the right side. In the other there was a congenital lesion of the heart, as shown by an increase of the cardiac dullness to the right, and an evident but slight murmur in the pulmonary area. One of Dr. GUTHRIE'S cases had extraordinary powers of imitation, mimicking all the technique of massage, feeling pulses, listening to chests with the stethoscope, simulating the walk of a hemiplegic patient, and pretending to carry on a conversation at the telephone. Dr. MORLEY FLETCHER said it was difficult for him to believe in the so-called typical hand of the Mongol, and pointed out that a more important peculiarity was the rough condition of the skin of the hand. Dr. SHUTTLEWORTH observed that there was still much confusion in the minds of medical practitioners as to the characteristic differences between Mongols and cretins. He also did not consider that thyroid improved the condition of Mongolian imbecility. He took a more cheerful view in regard to the results of careful training of these cases, especially in the better classes, where circumstances were more favourable for success. In his opinion a Mongol would be, however carefully trained, nothing but a hewer of wood and drawer of water to the end of his days, being only capable of imitation and doing that which he was in the habit of carrying out frequently. He agreed that the shape of the hand was not a universal characteristic in Mongolism.

Omentopexy.

Mr. JAMES SHERREN showed a patient, aged 34, who in April, 1903, underwent the operation of omentopexy for ascites due to cirrhosis of the liver. She had remained free from symptoms since. Mr. C. GORDON WATSON observed that in the majority of cases he had noticed the operation was a complete failure, and Dr. ROLLESTON said that cases suitable for this treatment were only met with occasionally.

Hereditary Defects.

Mr. H. B. ROBINSON and Mr. W. H. LLOYD showed a case of hereditary transmission of claw-hand and foot in mother and child. The child, 1 year old, showed claw-foot, and the mother had a similar deformity of her feet in addition to deformed hands.

Infective Gangrene.

Mr. W. F. FEDDEN read a paper on six cases of acute infective gangrene of the extremities. He considered that infective gangrene might be produced by a great variety of definite organisms—namely, the *Bacillus aerogenes capsulatus*, *Bacillus coli*, *Bacillus pyocyaneus* (vide Dudgeon and Sargent), *Streptococcus pyogenes*, and *Staphylococcus aureus*. It was a noteworthy fact that the bacillus of

malignant oedema did not find a place in any of the six cases. The prognosis of cases due to *Bacillus aerogenes capsulatus* was undoubtedly very much more favourable than in those due to streptococcal infections, whilst those due to staphylococcus appeared to hold an intermediate position. The period between infection and the appearance of actual gangrene in the first group was almost constant—namely, thirty to thirty-six hours, whereas in the group caused by streptococcus, this period might be as short as an hour. The incubation period of the staphylococcal group was very variable, but might be prolonged to several days. The importance of early amputation was self-evident, and was so urgent that the diagnosis must be made on clinical data, as the time for bacteriological confirmation could not be afforded.

SECTION OF DISEASES IN CHILDREN.

Friday, April 23rd, 1909.

Mr. R. CLEMENT LUCAS in the Chair.

The Vision of School Children.

MR. N. BISHOP HARMAN, in a paper on the effects of school-life upon the vision of the child, after reviewing previous statistics, communicated the results of the examination of 1,100 children seen at the Belgrave Hospital and the Middlesex Hospital. In all cases the eyes were under the influence of atropine, an ointment of 1 per cent. having been used four times a day for a week. Of every 100 children with defective vision, over 71 had hypermetropia, and less than 29 were myopic. These 100 children represent about 10 per cent. of the school children, hence the incidence of myopia amongst school children in London might be considered not to exceed 3 per cent. About 78 per cent. of the cases were girls. This he attributed to the girls having less outdoor exercise and not being in such a healthy condition, as well as to the fine needlework done by them. During the school age the incidence of hypermetropia increased, as might be expected from what was known of the growth of the crystalline lens. At the same time the curve of myopia rose upwards to the highest positions on the chart. Such a phenomenon led to the conclusion that the diminution of the hypermetropic astigmatism had been due to the transference of these cases to the myopic group. On the whole the condition of the eyes of London children was very fair, especially when compared with similar returns collected in Germany. The greater proportion of the cases of bad vision were due to natural conditions of the eye, that is, hypermetropia and hypermetropic astigmatism. Newborn infants were always hypermetropic. The incidence of "manufactured" bad vision—myopia and its associated astigmatisms—formed between a quarter and a third of the whole of the cases. The evidence of the deterioration of astigmatic eyes indicated the desirability of a special oversight of these cases. He did not think that a healthy school-life was harmful to the sight of the child population. In conclusion, he criticized adversely a paper on the inheritance of vision, recently published by Miss A. Barrington and Professor Karl Pearson. Titled to the conclusion that the increase of myopia was due to fate and hopeless, but in practice it was found that amelioration of school conditions and the relief of strain in ill-shaped eyes did stay the increase. Mr. SYDNEY STEPHENSON agreed that it was futile to examine children's refractions unless the accommodation had been paralysed by atropine. Some years ago he examined 6,000 eyes, under the Poor Law, in children ranging from 18 months to 18 years of age. In these he found myopia present in 6.68 per cent. That was not very different from Mr. Harman's figures when the different range of ages was considered. He agreed that among the poor children of this country myopia was not of serious frequency. In his own figures, the females were almost twice as much subject to myopia as were the males. He agreed in ascribing this to their employment in indoor work and lack of healthy exercise. Mr. ERNEST CLARKE said that although the subject was a tempting one, he would confine himself to reiterating what Mr. Stephenson had said as to the great importance of Mr. Harman insisting on the use of a cycloplegic. In default thereof, statistics concerning the refraction of young people, such as were commonly published, were useless.

LIVERPOOL MEDICAL INSTITUTION.

Thursday, April 22nd, 1909;

Mr. T. H. BICKERTON, President, in the Chair.

Amblyopia.

DR. A. A. BRADBURN, in a note on amblyopia ex anopsia, dealt with that type found in conjunction with high degrees of refractive error. He considered the cause to be a cerebral defect, and based his treatment on that theory. One of his cases, a boy aged 11 years, who had in six months' special training recovered vision from $\frac{5}{60}$ to $\frac{6}{60}$ or Jaeger 1. He considered that want of success in treatment was usually due to the defect being a complex one, the visual act depending on several centres. Mr. NIMMO-WALKER advocated the whole-time covering of the non-squinting eye until the vision of the squinting eye became equal to that of the other. This was possible in the majority of cases if taken early enough.

Intussusception.

MR. R. C. DUN, in a note on intussusception, based on an analysis of 73 cases, expressed himself as in favour of irrigation, which should be followed, if necessary, by immediate section. He had always used ether as the anaesthetic during operation.

Diagnosis of Syphilis.

DR. WILSON, in a paper on the serum diagnosis of syphilis, contrasted the value of Wassermann's and Noguchi's tests in a series of trials. Using Wassermann, 23 results were positive out of 30 cases. Of 20 controls 3 were positive, but in none of these could the possibility of syphilis be excluded. With Noguchi 40 out of 52 cases were positive, also 3 out of 25 controls. Out of 30 cases submitted to both tests, 22 were positive with both; 4 negative with both. Two were positive with Wassermann and negative with Noguchi. Two were negative with Wassermann and positive with Noguchi. The opinion expressed was that Wassermann, although the more complicated of the two, was the more reliable. Dr. ERNEST GLYNN referred to the fact that some cases of cancer growth gave the Wassermann reaction, and that guinea-pig's heart was as suitable an antigen as syphilitic liver. The serum principle has been successfully employed in the diagnosis of typhoid and gonorrhoea.

Thursday, April 29th, 1909.

Mr. T. H. BICKERTON, President, in the Chair.

The Treatment of Tetanus.

DR. LLOYD ROBERTS reported a case of tetanus which had recovered under treatment with injections of carbolic acid and of antitetanic serum. The disease followed an injury to the hand from a circular saw. Symptoms appeared ten days after the accident, and treatment was commenced on the sixth day of the disease. On the fourth and fifth day the symptoms had rapidly become more severe, and on the sixth day there was marked trismus, etc. The patient received 10 c.c.m. of serum every twelve hours, and 15 minims of a 4 per cent. solution of carbolic acid every three hours for one day, and subsequently every two hours. On the second day of treatment the disease appeared to be arrested, and the patient was well twenty days later. Twenty-six injections of serum and 236 injections of carbolic were given. The favourable result was attributed to the carbolic rather than to the serum.

Intraspinal Tumours.

DR. JOHN OWEN and Mr. DOUGLAS-CRAWFORD read a note on a case of intraspinal tumour which they had had under their care. It was localized at the eighth dorsal segment, and was successfully removed, the patient being shown at the meeting. They hoped to publish a full account of the case later. Dr. W. B. WARRINGTON discussed the rarity of these cases, and urged the importance of physicians having sufficient faith in their diagnosis to urge an operation.

Meningitis.

DRS. MARSH and O. T. WILLIAMS read a paper on meningococcal meningitis in children. They referred to the importance of lumbar puncture in the diagnosis of

tuberculous meningitis from other types of the disease. In the last 14 cases of tuberculous meningitis they had recovered the tubercle bacillus from the cerebro-spinal fluid. Four cases of tuberculous meningitis with secondary meningococcal infection were described in detail. The use of Flexner's serum had reduced the mortality from between 70 and 80 to 29.6 per cent. In children under 2 years the mortality was 42.4 per cent. in 59 cases, and in these the higher mortality was amongst those not treated until the seventh day of the disease. The serum was described and its effect both on the organisms and the cytology of the fluid; being bactericidal and only slightly antitoxic, the serum must be injected into the spinal canal. Fourteen cases of cerebro-spinal meningitis were considered. They varied in age from 3 months to 4 years, and 7 recovered. Three cases treated in the first few days of illness all recovered. The amount of serum used in each case varied from 10 c.cm. up to 130 c.cm., and the number of injections from 1 to 5. In infants they advised small doses of 10 to 15 c.cm. Dr. Flexner confirmed this view. In older children they followed Dunn of Boston, and gave 30 c.cm. on four successive days, the results upon symptoms and the fluid guiding their future procedure. They considered that this serum in early cases promised extremely good results, and even in later cases it improved the prognosis. Dr. OWEN referred to 1 case he had treated with Flexner with satisfactory results. Dr. GULLAN referred to 2; in 1 the fluid was not typical, nor was the diplococcus found. The patient recovered with Flexner. The second case, a girl of 13, had been ill a fortnight. After the first injection the patient passed into a state of coma, and, in spite of further lumbar punctures and injections, died. Dr. JOHN HAY referred to the occasional difficulty of differentiating in certain cases between acidosis and meningitis, and related a case illustrating the point.

GLASGOW SOUTHERN MEDICAL SOCIETY.—At a meeting on April 29th, Dr. PEDEN in the chair, Dr. ALEX. McLENNAN, in a paper on the newer methods of *Treatment of surgical sepsis*, described the present position of treatment by serums. Such serums, whether administered per os, per rectum, or per cutem, might be simple or antitoxic. As far as antitoxins were concerned, subcutaneous and intravenous methods in use were alike in efficacy, but this might not be so with reference to the other constituents of the serum. Oral or rectal administration was becoming more popular. Either method had been experimentally proved to be correct, as most of the known protective substances passed through the gastro-intestinal mucous membrane. Paton's advocacy of the oral administration of antiphtheria serum was now receiving support when employed for diphtheria and against sepsis. The serum might be dried, prescribed with other substances, or only partly concentrated. It might be given in pill form or in capsule. The uncertain action of the antiserum was probably due to the specificity of the antitoxin. Antidiphtheria serum contained, according to Paton and others, substances besides antitoxin which were antagonistic to a variety of pathogenic organisms. According to Paton, this was because the serum contained an antiproteolytic ferment, and, according to Metchnikoff, what he called "stimulin." Antidiphtheria serum was first employed locally by Paton. Ordinary serum concentrated was now applied to wounds or injected into abscess cavities after aspiration of pus. The action was explained on account of the antiproteolytic ferment contained in such serums. Ascitic and hydrocele fluids were rich in such antiferment. Cold abscesses, on the other hand, were wanting in proteolytic ferment, and here tryptic ferment could be used for injection. As regards the older methods, the cardinal principle was still the evacuation of pus and the drainage away of the exudate with its cause. The common mistake in the early stage of sepsis was to regard sedatives as treatment. The sphere of antiseptics was rather prophylactic than curative, so that the choice of such an antiseptic for dressing or douching was of minor importance. Dr. JOHN PATON, in a paper discussing the *Treatment of sepsis* by vaccines and Bier's hyperaemia, said he regarded the former as of little practical value, and pointed out that theoretically it should be able to cure typhoid carriers. A person's opsonic index also might be low as much because his

immunizing machinery had been used up by innumerable recurrent doses of vaccine from the source of his trouble as from any other reason. He had used Bier's passive hyperaemia in many cases of sepsis with excellent results. He strongly advocated this treatment as being simple, effective, and capable of being used in most of the forms of sepsis generally met with. Dr. ANDERSON considered that vaccines, though not of much practical value at present, were likely to be of greater use in the future. Dr. DUNLOP, in criticizing Dr. McLennan's paper, considered that the value of antidiphtheria serum was much overrated; personally he had no faith in it. Dr. PEDEN, in proposing a vote of thanks to the speakers, advocated a more general use of hyperaemia in septic cases.

ROYAL SOCIETY.—At an ordinary meeting on April 22nd, Sir ARCHAID GEIKIE, K.C.B., President, in the chair, Professor KARL PEARSON, F.R.S., read two papers: (1) On the theory of *Ancestral contributions in heredity*, and (2) on the *Ancestral genetic correlations* of a Mendelian population mating at random. The purpose of the two papers was to place in a somewhat clearer light the relationship of the biometric to the Mendelian standpoint. The law of ancestral heredity involved the following three points: (a) The linearity of the regression of offspring on any ancestor; (b) the diminution of the ancestral correlations in a geometrical progression; and (c) the determination of the probable character of the offspring when the mating was at random by the multiple regression formula. It was shown, in a memoir of 1896, that when the ancestral correlations were of the type $p, p^2, p^3 \dots$ then the character of the offspring depended only on the characters of the two parents and ancestry need not be considered. It was shown later that (a) and (b) held for a generalized Mendelian population, for the somatic characters, but that the somatic correlations were not of the type $p, p^2, p^3 \dots$ and accordingly that ancestry in the biometrician's sense did matter even in a population following the simplest Mendelian formula, providing the mating was at random. A recent paper in the *Proceedings of the Royal Society* might be interpreted as meaning that the law of ancestral heredity did not apply to a Mendelian population. In the first of the above papers Professor Pearson indicated how in a population originally consisting of p dominants, s recessives, and q hybrids, mating at random, the percentage of the number of dominants in the offspring increased with the number of dominants in the grandparentage, and this was true in the case of any grade of ancestors, whatever be p, q , and s . In the second paper he turned from the somatic to the genetic correlations, which were not discussed in the earlier memoirs, and showed that the genetic correlations form a series of the character $p, p^2, p^3 \dots$; in other words, a knowledge of the genetic character of the parents makes a knowledge of the somatic character of the ancestry unnecessary. Apart from symbols this must be a truism, because the offspring arises solely from the gametes of the parents. The Mendelian genetic correlations, whatever be the mixture of protogenic, allogenic, and heterogenic elements in the freely mating population, take the same values—that is, 0.5, 0.25, 0.125, etc., diminishing one-half with each ancestral grade. These genetic correlations were much nearer to the values obtained by biometric investigations for the somatic correlations, the theoretical Mendelian somatic correlations being considerably too small. It would thus appear that the Mendelian genetic correlations accurately obey the fundamental conceptions of the law of ancestral heredity, so that the only real outstanding antinomy lay in the principle of absolute dominance. The correlations found biometrically suggested that there was a closer relation between the genetic and somatic constitution—at least for certain characters—in the species investigated—than was represented by the first Mendelian principle of absolute dominance.

ON the initiative of Dr. Augagneur, Governor-General of Madagascar, a decree has recently been passed regulating the importation, sale, and keeping of opium in the colony. A decree was passed on August 31st, 1908, prohibiting opium-smoking dens, but it was found that without strict control over the introduction of the drug the enactment was likely to prove a dead letter.

Reviews.

A TEXTBOOK OF PATHOLOGY.

PROFESSOR ADAMI'S bulky *General Pathology*, which forms the first volume of his *Principles of Pathology*,¹ distinguishes itself from many books bearing similar titles by its independence of thought and originality of treatment. There is a refreshing atmosphere of personality about it all. The author takes up the problems of pathology as they present themselves to his own mind, sets out the facts which he finds important or interesting, and then presents the conclusions which appear to him to be warrantable. He is more interested in the elucidation of general principles than in elaborate accumulations of data, and by displaying the workings of his own mind in his effort to unravel fundamental laws he provides an example of how pathological problems ought to be studied, which will be particularly helpful to the reader desirous of seriously devoting himself to the science.

To understand pathology it is necessary to commence with physiological principles, and therefore Professor Adami devotes the first section of his book to the morphology, chemistry, and biology of the cell. This method of approaching his subject is undoubtedly correct from the scientific standpoint, though it adds greatly to the bulk of the volume. It makes us realize that we cannot hope to advance in pathology until we have mastered not merely the elements of physiology but its latest and most intricate developments. The minute details of cytological research, the organic chemistry of the complex compounds which form the basis of living matter, and the laws of development and inheritance, constitute three wide fields of knowledge, to each of which a man may well devote the whole of his energies; but the pathologist is expected to be familiar with them all, as part of his preliminary equipment for the investigation of morbid processes. Professor Adami's account of these "Prolegomena" to pathology is very condensed, but it is much more than a mere epitome of other people's work; it bears the impress of conscientious study and a matured capacity for appreciating the essentials of permanent value amongst a perplexing and almost overwhelming mass of experimental data.

Professor Adami conceives it to be his mission to bring about a closer union between physiology and pathology, and, in particular, to reinterpret pathological data in the light of recent research upon the properties of normal tissue. He says:

Physiology and pathology have for the last seventy-five years, at least, been divorced to this extent, that they have undergone development under separate influences. Under the influence more particularly of Ludwig and his pupils physiological research has been directed to the study of organs and tissues. The organ as a whole has been taken into account. . . . It is under the influence of another great master (Virchow) that modern pathology has been developed. His teaching was based upon exact study of diseased organs and the correlation between gross and microscopic appearances. It was largely histological, and, as a result, mass effects were followed back to the disturbances in the individual cells composing the tissue. In place of an organ, or tissue pathology, there was developed a "cellular pathology."

But it is recognized that the methods pursued by Virchow are insufficient for the requirements of modern pathology. Microscopic examinations of morbid tissues must be supplemented by experimental methods, for the initiation of which we are mainly indebted to the physiologist; the rapid advances of bacteriological knowledge have to be reckoned with, and, most especially, there is the vast field of work on immunity which has to be brought into perspective and correlated with other branches of pathology. To bring into focus the many and diverse aspects which are presented by the science of disease, to systematize them, and to unravel the underlying principles, this is the task which Professor Adami has set himself. It has not been a light undertaking; but the twelve years which, he tells us, he has devoted to the work have been well spent, and have resulted in the production of a work conspicuous for its broad grasp of general principles and comparable, in many respects, to

the pre-eminently philosophical treatise on physiology by the late Sir Michael Foster.

Commencing with the biology of the cell, this first volume goes on to consider the causes of disease, inflammation, the reactive processes associated with immunity, and the characteristics and classification of new growths and other tissue changes. In dealing with the causes of disease the author devotes much space, perhaps more than is necessary, to abnormalities of the fetus, and provides a very full collection of illustrations representing various types of monstrosities. His treatment of the subject of inflammation is excellent, but his opinions are too well known to require detailed discussion. His classification of new growths is very elaborate, and it may be doubted whether it will gain general acceptance; but it must at least be admitted that it is a serious attempt at scientific classification and in that respect preferable to the older, vaguer, and more familiar nomenclature. The various theories of neoplasia, including the author's "habit of growth" hypothesis, are impartially presented; and if the amount of new or important information to be elucidated from them is relatively small that is not the fault of the writer but is attributable to the obscurity in which the cancer problem is still involved.

APRAXIA.

DR. DROMARD² has written an interesting and in places illuminating book, which is not confined to the physiognomy of the insane, but includes also gesture, attitude and other forms of self-expression. The author discards for this purpose all the anomalies of conformation, asymmetries and other morphological characters so frequently exhibited by the insane and other so-called degenerates, and restricts himself to departures from the normal in intellectual, affective and volitional expression in the insane. The author does not, however, consider as abnormal in function—and this is of first importance in his treatment of the subject—the various characteristic expressive phenomena met with in insane people, so long as they are in harmony with, or equivalent to, the mental states from which they spring; that is, in all of the cases—and this, naturally, includes a large proportion of the insane—in which the modifications of expression result directly and strictly from modifications of the emotional life, the function of expression is considered to be intact. This, of course, considerably narrows the field, though what remains is still sufficiently great and, as Dr. Dromard's work shows, worthy of the most careful study. Thus, after showing how disorders of expression may depend upon defective adaptation—that is, when the play of face or the gesture does not adequately express the corresponding idea or emotion—or upon disordered function, where the expression in itself shows a lack of harmony and homogeneity in its constituent parts, the author considers under the head of disorders of voluntary or ideative expression: apraxia; the hypermimia of substitution; mannerism and puerilism; neologism; stereotypy and echokinesis; and under disorders of involuntary or emotional expression: paraminia; spasmodic expression, and dissociated expression. Taking apraxia (or the incapacity to perform a movement conformably to the end proposed, motility being preserved and presenting no obstruction to its proper performance) as paradigmatic of the author's exposition of his subject, this is considered under the heads of—

1. *Motor apraxia*, which may be brought about either (a) by the loss of kinesthetic representation in the senso-motorium; or (b) by the rupture of connexions between the senso-motorium concerned with motor innervation and the parts of the cortex involved in elaboration of ideas of movement (transcortical apraxia.)

2. *Ideational apraxia* (ideo-motor apraxia), when the disorder resides in the superior psychic function, attention, memory, association, etc., and

3. *Sensory apraxia*, or false apraxia, corresponding to the symbolic of Wernicke and the agnosia of Freud, due either to the loss of memory images or rupture of the connexions between these and new sensory impressions.

Obviously, in this last group the motor result may be correct in itself, responding adequately to perceptions which exist, however faulty; hence the use of the term "false apraxia" by the author. The term "apraxia" has.

¹ Oxford Medical Publications. *The Principles of Pathology*. By J. George Adami, M.A., M.D., LL.D., F.R.S. Vol. I, *General Pathology*. London: Henry Frowde, and Hodder and Stoughton, 1909. (Roy. 8vo. pp. 248, 322 engravings and 16 plates. 50s.)

² *La Mimique chez les Aliénés*. By Dr. G. Dromard. Paris: Félix Alcan, 1908. (Cr. 8vo. pp. 284. Fr. 4.)

thus for Dr. Dromard, a wide application. "Ideational apraxia," for instance, includes that due to failure of voluntary attention before the execution of any act, giving rise to many acts which have been variously ascribed to amnesic apraxia, "psychic blocking," "blocking of the will," etc., and also some forms of perseveration and flight of ideas. Another form of ideational apraxia is described by Dr. Dromard as due to interruption or to substitution during the course of execution of an act, and a third form as due to a faulty distribution of the representations of attention or the components of these representations. Ideational apraxia is thus entirely a disorder of intrapsychic processes whose diagnostic features it is important to recognize. The distinguishing features as given by Dr. Dromard are as follows: (a) Motor apraxia has a segmentary distribution, affecting particular motor levels and is rarely generalized; ideational apraxia, on the other hand, affects the movements of all parts of the body without distinction. (b) Motor apraxia is exhibited only in simple acts; ideational apraxia in movements somewhat complicated. (c) Motor apraxia appears generally in the imitation of movements; ideational apraxia in this form but rarely. (d) Amorphous movements and movements of substitution of a flagrant or a coarse character distinguish motor rather than ideational apraxia. Lastly, a detailed psychological examination of the patient, as a rule, reveals explanatory disorders in the case of the ideational apraxia but not in motor apraxia. The author's treatment of apraxia has been outlined here as an illustration of the method of psychological analysis sustained throughout the following chapters. The book is a valuable addition to the literature of expression in the insane. Its methodical classification furnishes many aids to diagnosis, helps to relate types of expression to corresponding structural cerebral disease according to the levels affected, and should undoubtedly facilitate the detection of the simulation and dissimulation of mental disease.

NEUROLOGY.

DR. R. T. WILLIAMSON'S book on *Diseases of the Spinal Cord*,⁴ dedicated to the past and present students of the Manchester Medical School, is based on notes of lectures delivered at that school during the last fifteen years. The main adverse criticism that suggests itself is that the treatment of the subject is slight; considering, however, that the work is not intended, as the author states, to furnish an exhaustive account of spinal diseases, and considering the form and scope of its fellows in the series of Oxford Medical Publications, that criticism may be really rather praise than blame. The book, then, is a really good one. It is well balanced and sound in its teaching. On controverted points—on pathogenesis, for example—it gives a fair statement of the conflicting views of different schools, and then, in what may be considered a too modest way, gives its own judgement, and, as many well able to decide will think, generally on the right side. It is thoroughly up-to-date, including not only recent advances in the clinical facts of cases of nervous disease, but also such matters as the use of lumbar puncture in diagnosis and Frenkel's method of treating ataxia. It is practical, giving ample space to differential diagnosis and to such treatment as nervous diseases are susceptible to, including the contribution of orthopaedic surgery to the matter. It is well and helpfully illustrated with clinical photographs, anatomical and physiological diagrams, and pathological microphotographs. It is plainly and well written. The minor errors it contains suggest somewhat rapid production of the printed page; a lesion of a spinal posterior root, for example, is said to cause anaesthesia in the distribution of that root, a statement combated, on the evidence of Professor Sherrington, on a subsequent page; peripheral neuritis is said to be easily confused in diagnosis with anterior poliomyelitis, a statement only true if multiple and not terminal neuritis is meant; a diagram is given representing cerebral anaesthesia in the form of a deeply shaded gauntlet, but the area shown could not, from its shape, be subcortical in origin, and if cortical, as the text suggests, it would not be absolute, and should be differently shaded. There is a welcome appendix dealing with the methods for the patho-

logical examination of the spinal cord. There are, in short, many textbooks on the same subject dealing more systematically with the subject, but there are few likely to be more practically useful to the medical practitioner.

DR. ALFRED GORDON, whose name is known in association with the recognition of the paradoxical plantar reflex—an earlier sign, it is claimed, of interference with the pyramidal tracts than Babinski's phenomenon—has written a short and thoroughly sound textbook on *Diseases of the Nervous System*.⁵ As he says, to both general practitioner and medical student neurology has always appeared a difficult subject, and their continuous complaint has been that they could not find any book which would give them a plain and practical account of diseases of the nervous system. Whether this charge be true or not, Dr. Gordon has written a book which, to a large extent, refutes it, though there may be several others equally good in the English tongue published, either in America or in this country. The book is a good one, and it may safely be used by the tiro. On the other hand, it and its fellows are of very little use, except in regard to cases which may be called typical, or, at any rate, which are capable of being pigeon-holed. Neurology, above all other branches of medicine, is largely concerned with atypical cases, and hence the special value of the larger book. It is only fair to say, however, that this book contains chapters on the anatomy and physiology of the central nervous system and on the methods of examination for the diagnosis of nervous diseases, so that it is, in a sense, complete in itself. It is a trustworthy book, and the most unfavourable criticism that suggests itself is that it is too large for a primer of neurology and not large enough for final reference.

PAIN IN VISCERAL DISEASE.

THE value of pain as a guide to diagnosis is always difficult to assess. It is probable that every practitioner of medicine or surgery forms his own opinions on the subject, and acts upon them without much reference to the written law. But the manifestations of pain are so extraordinarily varied, that a systematic examination of them recently issued by Dr. RUDOLPH SCHMIDT of Vienna, and translated by Drs. VOGEL and ZINSSER of Columbia University,⁶ cannot fail to be of use as a work of reference, and as a reminder of the diagnostic importance of pain, even to those who might not in all cases agree with the opinions of the writer as to its causation.

The book deals with the interpretation of pain produced by internal diseases, and is prefaced by some useful reflections upon pain in general, followed by chapters on the various influences such as position, motion, pressure, food, etc., by which pain may be modified. The topography of pain, and its quality and times of occurrence, are also examined, and special attention is then directed to the pains which may accompany disorder of the various systems—nervous, digestive, urinary, etc.

The book presents a very full account of most of the aches and pains to which humanity is liable, and errs only in its lack of simplicity of expression, and in its tendency to repetition of detail. It would gain in practical value by closer compression, and by the omission of much that can only be matter of indefinite speculation, but it contains a great deal worthy of careful reconsideration, particularly in relation to the pains of colic from various causes. The final chapter is devoted to an illustrated exposition of Dr. Henry Head's observations on cutaneous tenderness in visceral disease.

ANIMAL PARASITES.

BRUNN, in collaboration with LÜHE, has compiled a volume intended to serve as a guide to the examination of the animal parasites of man and domestic animals⁷ for

⁴ *Diseases of the Nervous System*. By Alfred Gordon, A.M., M.D. Paris. London: H. K. Lewis, 1908. (Roy. 8vo, pp. 499, illustrations 136, 12s. 6d.)

⁵ *Textb.* By Dr. Rudolf Schmidt, Vienna. Translated and edited by Dr. Karl Vogel and Dr. Hans Zinsser, Columbia University. London: T. Fisher Unwin, 1908. (Demy 8vo, pp. 326, 12s. 6d.)

⁶ *Leitfaden zur Untersuchung der tierischen Parasiten des Menschen und der Haustiere für Studierende, Ärzte und Tierärzte*. Von Dr. M. Brunn, O. O. Professor der Zoologie und Vergl. Anatomie und Direktor des Zoolog.-Museums in Königsberg i. P.R., geh. Regierungsrat, und Dr. M. Lühe, Privatdozent und 1. Assistent des Zoolog.-Museums in Königsberg i. P.R. Würzburg: Curt Rabitsch (A. Stuber's Verlag), 1909. (Sup. roy. 8vo, pp. 134, 100 Abbildungen im Text, M 5.20.)

⁷ *Diseases of the Spinal Cord*. By R. T. Williamson, M.D., F.R.C.P. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton, 1908. (Roy. 8vo, pp. 443, 15s.)

students, doctors, and veterinary surgeons. A glance at the general style, printing, diagrams, and text of the work show at once that it is based upon, or might even be termed a synopsis of, Brauer's well-known work on the animal parasites of man, with some additions. It is divided into three parts—(1) Protozoa, (2) Helminthes, (3) Arthropoda, Dr. Lühe being responsible for the first part and Professor Brauer for the other two. It is apparently fashionable now to change or invent new classifications for different groups of the animal kingdom, and Dr. Lühe keeps up to date by introducing considerable changes into the old and time-honoured classification of the protozoa. The most important of these are that he makes the haemoflagellates and haemosporidia the third order (binucleata) of the class flagellata, that he obliterates the class sporozoa as such, its place being taken by the class sporozidia with—in addition to the micro-, myxo-, and sarco-sporidia—one new order—the actinomycetozoa, and by the class telosporidia, containing the coccidia and gregarinida. These last changes are not so much to be quarrelled with, but how any one, protozoologist or other, can believe that the trypanosomes and malarial parasites are so near each other as to be properly comprehended in one order is past comprehension. Schaudinn's unconfirmed work on the haemoproteus (the old halteridium) is again no doubt responsible. It ought either to be verified once and for all or finally swept away. It has misled too many of the unwary already. The helminthological part of the book contains some useful information on the preservation of the different worms and their eggs, but many well-known and useful methods are omitted. Life-histories of the dog taenia, *T. marginata*, and others are valuable because good short accounts are in many instances very difficult to obtain. All things considered, however, the work, though interesting in many particulars, falls short of expectation; it is not full enough for advanced students of the subject, and as a mere narrative for non-helminthological and protozoological people it is too full and scientific. It is rather hard to understand the necessity for its publication, especially when it is remembered how fully the animal parasites of man have been dealt with by one of the authors. Still, as a guide or introduction to this larger work, it may prove of use.

TICKS.

THE subject of ticks had been little studied, at least by medical men, until it came to be established that these parasites might spread disease from animal to animal, or even to man. This fact having been proved, a book on these insects was clearly required, and Dr. NUTTALL, in conjunction with Messrs. WARBURTON, COOPER, and ROBINSON, has done well to provide *Ticks: A Monograph of the Ixodoidea*.¹ At first the idea was to publish a full account of the ticks as a complete volume, but for various reasons the authors have decided to bring the work out in parts: these will be complete in themselves, but are designed to form a volume of about 500 pages, when all have been published, and it is hoped that they will be ready in about a year. Part I deals with the Argasidae, and is divided into two sections: (1) the classification of the Argasidae; (2) the general biology of the Argasidae, the effects of their bites, their relation to the spread of disease, etc. For those unacquainted with the subject it will be sufficient to state that the ticks are classified as follows: Superfamily Ixodoidea: Family I, Argasidae. Family II, Ixodoidea. It is with the first of these, then, that the volume deals. Classification is always a tedious and difficult piece of work, and it seems uncertain yet how many genera the family Argasidae contains, but the usual plan of dividing it into Argas and Ornithodoros is maintained. Six well-established species, according to the authors, are found in the first,

eleven in the second. How long this will last no one can say, as it is probable that in the course of time as attention is directed to the subject, many more ticks will be discovered either specifically or generically distinct. Still it is to be hoped that the classification will never fall into the chaotic condition reached in the case of the mosquitoes. The part of Section II which deals with the relation of the ticks to the spread of disease is interesting; but again, the subject is largely in its infancy, and the same is true with regard to many points in the life-history. It is not quite clear when or where in the book the anatomy of these parasites is to be discussed, a note at the foot of page 8 simply stating that the internal anatomy will be considered in the general introduction to the completed volume. It might, perhaps, have been better to have taken up the anatomy, external and internal, first, then to have dealt with classification, and lastly with biological points, and the relation of the insects to disease, etc. When the work is complete, these matters will no doubt smooth themselves out, and too much praise cannot be given to Dr. Nuttall and his collaborators for taking up this difficult and somewhat thankless task.

DERMATOLOGY.

WORKS on diseases of the skin follow one another with such rapidity and have such a family likeness that it is difficult to deal with them in a critical as opposed to an expository manner. One of the latest books is by Dr. SCHAMBERG, of Philadelphia;² but in this case, following the example of the old Vienna school, the eruptive fevers are included, and their morbid cutaneous manifestations thoroughly discussed. Although the specific fevers are part and parcel of general medicine, yet it cannot be overlooked that a comparison of their rashes with skin diseases proper is of importance in practice. The first part of the book is devoted to diseases of the skin, the various conditions being dealt with in a very succinct, and, from the point of view of dermatology, in all too brief a manner. In the case of pemphigus acutus, the author does not allude to the severe febrile bullous eruption in butchers, which should have found a place in a work such as this, one which includes eruptive fevers in its title. The term "tubercular" as applied to certain syphilides and to a clinical form of leprosy is not so appropriate as "nodular." The second part, dealing with the eruptive fevers, is well done, and the discussion of differential diagnosis can be recommended, for not only are the specific rashes carefully described, but the aberrant forms and the various prodromal and intercurrent eruptions are also dealt with. The book is profusely and well illustrated, and reflects credit on the publishers.

Professor Dr. S. RÖSA, in a short work on dermatological propaedeutics,³ has attempted to give a preliminary outline of the processes at work in the production of diseases of the skin. The book consists of the substance of a course of lectures, and contains seven chapters. The first chapter, dealing with the various agencies causing damage to the skin, is clear and concise, but needs no special analysis. The chief interest and value of the book lies in the second, third, and fourth chapters, which deal with constitutional peculiarities and acute and chronic inflammation. Considering the difficulty of giving anything like a complete review of such a complicated subject within a small space, the author has certainly achieved a marked success. The principles of general pathology are well explained, and the opinions of such authors as Marchand and Maximow discussed. The last three chapters are devoted to the application of the knowledge acquired from the first four to the special domain of cutaneous medicine, and a careful perusal of the whole book would repay not only those commencing the study of dermatology, but also those whose early training was undergone before pathology had attained its present importance in medicine.

¹ *Ticks: A Monograph of the Ixodoidea*. By George H. F. Nuttall, M.A., M.D., Ph.D., Sc.D., F.R.S., Fellow of Magdalene College, Oxford Professor of Biology in the University of Cambridge; Cecil Warburton, M.A., F.Z.S., Christ's College, Zoologist to the Royal Agricultural Society; C. W. F. Cooper, B.A., F.Z.S., F.L.S.; and L. B. Robinson, A.R.C.Sc.Lond. Part I, Argasidae: October, 1908. Cambridge: At the University Press: London: Cambridge University Press Warehouse, and H. K. Lewis: New York: G. P. Putnam's Sons; Leipzig: Brockhaus; Berlin: A. Asher and Co. Bombay and Calcutta: Macmillan and Co., Ltd. (Imp. 8vo, pp. 150, figs. 116, pl. 3, 5s.)

RECENT BOOKS. NOTES ON BOOKS.

*Indian Plants and Drugs*¹ seem to be a favourite theme with Indian medical authors. Mr. K. M. NADKARNI, who has recently published a book on this subject, does not appear to possess a medical qualification; but from the statement that he has "cured cases with marvellous beneficial results in competition with the Western allopathic system," it is evident that he engages in medical practice. This treatise contains descriptions of 419 plants and drugs arranged alphabetically according to their botanical names. In each case the synonyms, habitat, properties, and uses of native Indian preparations are given. Some of the latter are marvellous faragoes, many of them covering half a page. The shortest we have met with is the direction that "as a purgative castor-oil is recommended to be taken with cow's urine." The article on cinchona is only one page long, and quinine is recommended to be administered in agues in doses of "1 to 2 grains three times a day." There is an "index of diseases and remedies," which is crude and complicated. "Fever" constitutes one entry, which includes about fifty references, among which "cinchona" is included. Under "Syphilis" no mention is made of mercury, and under "Dysentery" none of ipecacuanha or potassium sulphate. Altogether the compilation hardly redeems the promises of utility advanced by the author in his preface.

We have received a copy of a new edition of the *Students' Pocket Prescriber*,² by Dr. H. AUBREY HUSBAND. It is a book of vest-pocket size, containing some 397 thoroughly constructed prescriptions and a short preface dealing with the art of prescribing. The counsel given in this seems for the most part sound, but we are not sure that it is a universal rule that women require smaller doses of purgatives than men, or that the fact that in marshy districts people take large doses of quinine is really proof of the modifying influence of climate on therapeutic action.

¹ *Indian Plants and Drugs, with their Medical Properties and Uses.* By K. M. Nadkarni, F.S.Sc.L.A. London: Madras: Norton and Co. 1903. (Cr. 8vo, pp. 450.)

² *The Students' Pocket Prescriber.* By H. Aubrey Husband, M.B., F.S.C. Edinburgh: E. and S. Livingstone. 1903. Pp. 175. (1s. 6d.)

HYGIENIC AND SANITARY APPLIANCES.

Sterilizable School Boxes.

THE danger of allowing the indiscriminate use of pencils and other writing utensils in elementary schools has long been recognized, especially in connexion with the spread of diphtheria; it has led to the more or less complete abolition of school slates, and various devices have been suggested for keeping each child's apparatus separate. Dr. W. Lloyd Edwards, school medical officer to the Barry education authority, has sent us a sample of a box made for that authority by the South Wales Canister Company, Swansea. It is a long, thin, flat, tin box, with places for rubber, pencils, and brushes, and there is a depression on the lid, which is hinged, for a label with the child's name. The box is a very practical invention, and could, we presume, be supplied at a small cost.

A box with the same object and of a similar material is made by Mr. George W. Jeffs, Watkin Works, Bromsgrove, near Birmingham, and is known as the Watkin hygienic pencil-box. It has a sliding lid, and holds a 9-in. ruler, pencil, rubber, brush, and compass; the price is 3d. each net. A somewhat more ambitious contrivance is a scholar's material box made of tin. The lid of the box may be fixed to the under side of the desk by screws, for which holes are prepared in the lid. The top sides of the box are bent outwards and slide into grooves in the lid; the box may be opened and shut like an ordinary drawer, or, if preferred, the bottom of the box may be fixed to a shelf underneath the school desk by screws, and the lid then slides on and off. This material box, which is retailed at 1s. 6d. net, has separate compartments for reading books, exercise and drawing books, ruler, brush, pencil, etc. The same maker manufactures an adjustable book-cover of stout brown paper with a very glossy surface; it is not likely to collect dust, and when soiled can be burnt; the book-covers cost 12s. to 20s. a gross, according to size.

PROPOSED antivivisectionist legislation has had a set-back in New York State, as at Massachusetts. Two bills have been before the State Legislature; on one the Assembly Committee decided not to report, while on the other the Senate Committee took no action.

Nova et Vetera.

THE MEDICAL JOURNAL OF A HUNDRED YEARS AGO.

THE unreflecting reader of the periodical medical literature of the present day does not realize the richness of the possession which is his. In this month of May, 1909, let him look for a minute or two into the *Medical and Physical Journal* for the corresponding month of 1809. It consists of 88 pages octavo, and, as it was a monthly publication, these pages constituted the whole supply of mental pabulum given by the editors to their readers for May. The publication had been established in 1799, with T. Bradley and F. M. Willich as editors; and, as two volumes appeared each year, this was vol. xxi. It continued under its original title till 1814, when it became the *London Medical and Physical Journal*, and was conducted by Samuel Fothergill. The contents of the May number consisted of some thirteen original articles, most of which take the form of letters to the editors, are not preceded by any indication of the subject with which they are to deal, and carry the writer's name only at the end; these articles, which occupy 62 out of the 88 pages, are followed by 12 pages in which are analysed very fully the articles appearing in the recent number of the *Edinburgh Medical and Surgical Journal*; then comes an editorial of 5 pages on the "Trial of Mr. Angus and subsequent Pamphlets"; then a report (of 3 pages) of the diseases of Edinburgh for March, 1809; then a short Account of Diseases in an Eastern District of London from March 20th to April 20th, 1809; then some Udiometrical, Thermometrical, and Barometrical Statements, by Dr. T. Pole, of Bristol; then an angry letter to the editors, beginning, "Gentlemen," on the subject of vaccination; and the number is brought to a close with some paragraphs of Intelligence, including the statement that "Dr. Adams, having finished his *Inquiry into the Laws of Epidemics*, is at leisure to complete his edition of Mr. Hunter's *Treatise on the Venereal Disease*."

In these parts, which constituted the medical journal of a hundred years ago, the observant reader will recognize most of the departments of a modern periodical; to adopt embryological language, for the nonce, their *anlagen* were in existence in 1809, but, as one sees, they have developed wonderfully since then.

Let us look more in detail at one or two of the contents of this journal. The place of honour is given to a contribution from the pen of Robert Jackson, M.D., No. 3, Panton Square, London, dated March 26th, 1809. We may note in passing that the practice of adding the writer's address to his communication—which we are, perhaps, inclined to associate with transatlantic medical journalism—was common, if not general, among our medical ancestors in London a hundred years ago; we also observe that in those early days manuscript was not allowed to lie long wasting its sweetness in the editorial cupboard.

Dr. Jackson's article, which as usual is without a title, begins well. We read:

Gentlemen, As you seem always ready to put before the public such hints or suggestions on medical subjects, as you may receive from persons of credibility and good intention, I am induced to submit to your consideration a short notice of the effects of a remedy which some may perhaps regard as too vulgar to be admitted in the physician's catalogue, or which others may be disposed to disparage, as it is not brought from a foreign country, or does not find a place in the apothecary's shop.

The reader's curiosity cannot fail to be roused and his appetite whetted by these introductory remarks, and the writer does not long keep him in suspense. Dr. Jackson promptly reveals his secret; like an earlier writer, he has a "naked thought" for which he wishes at once to find suitable apparel.

The spider's web (vulgarily cobweb) is known to many of the common people as a cure for fever and ague; but I believe that few of the regular practitioners have yet employed it on that or any other account.

The secret is out! Then the writer proceeds to say that he got the hint in the year 1800 from the late

Dr. Gillespie of Edinburgh, "a man of great candour and sincerity of character," and that he had himself tried the remedy with the best effect upon "some intermittents" in the army dépôt at Chatham. A Sergeant Anderson's case is mentioned; his ague attacks yielded before the assault of the cobweb pill. Upon a soldier of the Buffs recently returned from the West Indies—it will be remembered that it was in 1809 that Britain captured Martinique and Guadeloupe—a cobweb pill had so marvellous an effect that "in less than a minute he was perfectly tranquil." Other remarkable successes are reported, and it is thought that the usefulness of the remedy may be extended to hydrophobia, "for its tranquillizing effects." There is to be no secrecy: "pure cobweb is to be procured and made into pills, each containing 4 grains." So we see that a hundred years ago the doctors of London were being counselled to fight malaria with the means employed by spiders to capture flies. Now, for the same purpose, we attempt to exterminate the *culex* with our mosquito brigades, or at least try to keep off the mosquitos with our nets. What verdict, we wonder, will the medical journal of 2009 be passing upon our 1909 methods?

The second article is on "Epidemic Measles," by Dr. Ferguson, of Aberdeen. In the course of the paper the writer refers to a personal experience he had. He was examining an abscess on the thigh of a patient suffering from small-pox: he became faint and ill, and in a few days was found to be affected with "violent scarlatina anginosa." He argues that, "from the putrefactive process of small-pox, contagion may be produced which will occasion other infectious diseases." The editors are not inclined to agree with Dr. Ferguson, and courteously but firmly tell him so, in a note at the end of his communication. They say:

In the interesting account Dr. F. gives of his own case, we should suspect that the disease in his throat, and subsequent efflorescence on his skin, was the effect of putrid matter applied by effluvia to that semicircular and highly sanguiferous part, the throat.

The observation is, at any rate, of interest (whatever be the explanation) in view of what is now known regarding mixed infection.

There are surgical as well as medical articles in the journal. "Verax" tells of "a nobleman of considerable importance in the State" who had an accident which produced a seriously contused urethra; the treatment, which was successful, is described. Regarding the pseudonymous "Verax," there is a footnote to the effect that the name of the author, "which is highly respectable," is in the possession of the editors. There are also articles on permanent stricture (by Dr. Robertson); on the use of stimulants in burns (by "Philanthropus"), illustrated with a plate showing a bed for nursing such cases; on wounds of the scrotum (by Mr. Scott); and on lockjaw and tetanus (by Mr. Howship). Midwifery is represented by an article on that fertile subject of articles, the use of the forceps; in it the author points out that there are difficulties in the application of the forceps when the child's head is on the perineum! An expression is used in this article which is evidently the equivalent of our modern term, the "caput succedaneum"; the writer calls it the "presenting cone of integuments."

Among the more general papers in the journal are two on the trial of Mr. Angus for murder and on the so-called Liverpool controversy which followed it. An explanation of this matter would occupy too much space; but it was a *cause célèbre* of the time, and we may return to it again. There is an unsigned letter on what the writer calls "A Fraud of Authors." The fraud consists in the publication of second editions of medical works with additions, corrections, and improvements, to the detriment of the purchasers of the first edition. The writer is indignant:

How, think you, do the purchasers of the first edition feel? Why, that they have been buying a work, and that perhaps at an expense (*sic*) which they could but just afford; and in the short space of a year, or year and half, it is become of scarcely any value. . . . Is this fair to the purchasers of the first edition, who have paid the first compliment to the author, and who by so doing, and by speaking of the work as it merited, (probably) have been the cause of the rapidity with which the first sold. Is it honourable? Is it just?

The writer gives some details, and closes with:

Pray, Mr. Editors, take up this matter in the behalf of such unfortunate men as myself. . . . I feel grievously hurt.

In a footnote the editors indicate that they publish the letter with hesitation; but as a similar one had appeared in a rival journal, they could not, "without the suspicion of great partiality," refuse it a place. Certainly there was a refreshing frankness and an almost childlike self-revelation in the letters and in the editorial comments on them of the medical journals of a hundred years ago!

THE COMPOSITION OF CERTAIN SECRET REMEDIES.*

XXIV.—RADIUM SALVE.

LONG advertisements have appeared recently in the daily papers of a radium salve stated to have been discovered by Dr. S. Saubermann, who gives an address in Berlin. The salve is sold in this country by a company which describes itself as "manufacturing chemists to the medical profession." We are told in a pamphlet issued by this company that Dr. Saubermann's formula has been embodied and improved upon in the radium salve they sell. It is stated further that the salve is impregnated with the "radium salt in the proportion of 1 in 500,000," a quantity which "must not be exceeded, as otherwise the absorption by the skin and the well-known action of the strong and penetrating rays will do more harm than good." It is described as a remedy for lupus, cancer, and all diseases of the skin, with a bountiful "etc."

The company also sells various other preparations: A medical soap, a blood purifier, and an elixir of life. A certificate purporting to have been given by Dr. Saubermann in December, 1907, states that the ore which the company has acquired was "uranium refuse concentrated from the mines at Joachimsthal." In the advertisement a list is given of "leading scientists on radium," but the advertisers do not go so far as to say that any of them have anything to do with the radium salve. There is also a quotation from our own columns, which we need hardly say had no reference whatever to the salve or its manufacturers.

The salve is "sold at 2s. 9d., 5s., 10s., 20s., and 30s., according to radioactivity." Mr. Frederick Soddy, M.A., Lecturer on Physical Chemistry and Radioactivity in the University of Glasgow, has been good enough to examine the salve for us, and the following is his report:

"I received the two pots of radium salve you sent me, and have examined the radioactivity of the stronger preparation—namely that marked 'Strong, 5s.' The alpha radioactivity of the preparation is just detectable, and is about one-hundredth part of that of uranium. The beta radiation is too feeble to be detected by a sensitive electroscope. For comparison I might mention that the residues from the uranium ore of Joachimsthal, which forms the initial raw material from which radium is extracted, have an alpha radioactivity about four times that of uranium."

THE fifth International Congress of Medical Electrolgy and Radiology will be held at Barcelona on September 13th to 18th, 1910.

THE American Proctologic Society will hold its eleventh annual meeting at Atlantic City, New Jersey, this year on June 7th and 8th under the presidency of Dr. George D. Evans of Dayton, Ohio. Among the papers to be read are the treatment of pruritus ani, by Dr. W. M. Beach, and another on the same subject by Dr. T. Chittenden Hill; a consideration of the prophylaxis and treatment of cicatricial rectal stricture, by Dr. Alois B. Graham; the use of spinal anaesthesia in rectal surgery, by Dr. Collier F. Martin; intestinal auto-intoxication: its treatment by irrigation, by Dr. W. L. Dickinson; diseases of the colon and rectum as caused and influenced by pathological conditions of other abdominal and pelvic organs, by Dr. A. Bennett Cooke; the necessity for routine examination of the rectum in intestinal diseases, by Dr. Dwight H. Murray; naevus of the anal region, with report of a case, associated with internal haemorrhoids, by Dr. Lewis H. Adler, of Philadelphia, who is the Secretary-Treasurer of the Society.

THE ROYAL COMMISSION ON THE POOR LAWS AND RELIEF OF DISTRESS.

REPORT ON IRELAND.

THE Royal Commission on the Poor Laws and Relief of Distress issued its report on Ireland on May 3rd. As in the case of the report on England and Wales, it consists of a Majority and a Minority Report, the former occupying eighty-three pages and the latter two and a half. Dr. Downes refrains from signing either report, on the ground that his acquaintance with Irish affairs is insufficient to warrant him in so doing.

In some introductory paragraphs it is pointed out that at the date when the Royal Commission was appointed a number of inquiries by Royal Commissions and parliamentary and departmental committees had recently been conducted, or were actually proceeding, in reference to many subjects which came within the terms of reference of the Commission. It accordingly, while undertaking to consider any serious objections, invited no evidence in reference to the recommendations already made by other bodies, and decided to accept generally these recommendations and the evidence on which they were based unless they were considered to be inconsistent with any general principle advocated as a foundation of the Royal Commission's scheme of Poor Law reform. In this way it was possible to take full advantage of the exhaustive inquiries of the Vice-Regal Commission on Poor Law Reform, which it appeared to the Royal Commission had been received with general approval in Ireland. The Royal Commissioners, however, visited Ireland and heard evidence from Mr. E. Bourke, Senior Inspector of the Irish Local Government Board, in which Irish Poor Laws and their administration were fully explained, with special reference to differences in the system in England and in Ireland. The Medical Commissioner of the Irish Local Government Board, Mr. T. J. Stafford, C.B., F.R.C.S.I., supplied a memorandum on Poor Law dispensary medical relief in Ireland, and gave evidence which was found especially interesting "as the medical dispensary system in Ireland is a more comprehensive system of medical relief for the poor than has existed hitherto in Great Britain." Subcommittees visited various institutions in Dublin and its neighbourhood, and thereafter the Commission divided itself into three bodies to visit workhouses, hospitals, and other institutions, and to attend meetings of boards of guardians. Altogether, about one-third of the unions in Ireland were visited, and a report on these visits is promised in the twenty-eighth volume of the Report of the Royal Commission. The Commission also made enquiries with regard to distress arising from unemployment, a matter not included in the reference of the Vice-Regal Commission. A census of the persons relieved in Ireland on March 31st, 1906, classified by age and physical condition was made, and summary tables are to be printed in Volume XXXI of the Royal Commission's report. The arrangement of the report on Ireland is similar to that of the report on England and Wales, and the recommendations are generally similar.

RECOMMENDATIONS.

They include the abolition of boards of guardians and general workhouses; the appointment of public assistance authorities, the county or county borough being the area of administration and of rating; the continuance of outdoor relief under proper safeguards, and the creation of detention colonies or labour houses under the supervision of the General Prisons Board for the reception of persons not amenable to ordinary discipline, or who neglect or refuse to maintain themselves or their families.

Medical Relief.

With regard to medical relief, the following recommendations are made:

That the present dispensary medical service be a county service under the control of the Public Assistance Authority, and that the areas of the districts, where possible, be enlarged in view of present population.

That county infirmaries, workhouse, and other rate-aided hospitals be co-ordinated, and that medical relief generally be under the management of the Public Assistance Authority, and that a county ambulance system be established.

That a county medical superintendent officer of health be appointed, who shall also discharge the duties of bacteriologist.

That Public Assistance Authorities have power to appoint nurses for nursing in the homes of the necessitous, in the same way as boards of guardians at present appoint midwives.

Children.

The maintenance of children in workhouses should, it is said, no longer be considered a legitimate way of dealing with them, and the Royal Commissioners agree generally with the recommendations of the Vice-Regal Commission with respect to children, strongly advocating the extension of boarding-out, but deprecating any relaxation in the inspection of boarded-out children.

Aged and Infirm.

The Royal Commissioners further recommend that the necessitous aged and infirm be accommodated in a number of specialized institutions, preferably in small homes or almshouses, and that there should be powers of compulsory removal to institutions in the case of sick or feeble old people without friends to take care of them.

Defectives, Epileptics, and Lunatics.

The Royal Commission recommends that the Public Assistance Authority should be authorized to contribute to the maintenance of the deaf, dumb, and blind in institutions, and that a person should not be disfranchised on account of such assistance rendered to a dependant being deaf, dumb, blind, or belonging to any class of the afflicted poor, such as the epileptic, lame, deformed, etc.

Lunatics, idiots, and sane epileptics, it is recommended, should be maintained in asylums or institutions, as advised by the Vice-Regal Commission, and disused workhouses should be used as auxiliary asylums for the purpose.

THE MINORITY REPORT AND ITS OFFICIAL CRITICS.

The Minority Report signed by Prebendary H. Russell Wakefield, Mr. Francis Chandler, J.P., Mr. George Lansbury, and Mrs. Sidney Webb, in which they criticize the Majority Report mainly on the ground that it diverges from the recommendations of the Vice-Regal Commission.

In a memorandum the Bishop of Ross and Sir H. A. Robinson, the members appointed to the Royal Commission specially to represent Ireland, criticize the Minority Report, and after noting that the minority agree with the majority as regards the abolition of boards of guardians and the adoption of county rating for all Poor Law purposes, make the following damaging observations:

"The most important part of the minority's proposals, and that upon which the whole structure of their alternative scheme depends, is that outdoor relief should be taken out of the hands of the elected representatives of the ratepayers or their nominees and entrusted to salaried officers to be appointed by the county councils.

"The various committees of the councils will, it is true, be permitted to submit recommendations for outdoor relief to these paid officials—registrars, as they are styled—but the registrars are to be at liberty to act upon them or to disregard them as they see fit.

"We do not believe that committees in Ireland would be found to take any part in the administration of outdoor relief upon these terms; it would be too much to expect intelligent business men to spend their time investigating applications if they were powerless to ensure relief being given to those who they were satisfied were fit recipients.

"The number of paid officials in Ireland is already a heavy tax on the local ratepayers, and we strongly deprecate the proposal to flood the country with a new class of paid officer, even though the councils are to obtain the compensating advantage of paying for persons of the superior order of intelligence which will enable them to keep the committee straight and correct their blunders in the matter of outdoor relief.

"What would happen in the event of a council electing a registrar who was no better informed than the committee themselves on the subject the authors of the scheme do not appear to have considered.

"The only other point to which we must refer is the solemn warning uttered by the minority against our scheme of reform, on the ground of its being the result of an inquiry as hasty and perfunctory as that which they describe as Sir George Nicholls's 'celebrated scamper' through Ireland in 1837.

"This criticism comes somewhat badly when accompanied by an alternative scheme prepared by four members of the Commission, two of whom did not visit Ireland at all, while the time spent in the country by the only member who accompanied the Commissioners on their visits was even shorter than that occupied by Sir George Nicholls's visit, which on account of its brevity, has called forth such a severe condemnation from the minority."

THE WELLCOME RESEARCH LABORATORIES, KHARTOUM.

THIRD REPORT.

"THE third report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum, contains a wealth of material. The first report, it will be remembered, appeared in 1904, the second in 1906. The new volume is larger and fuller than its predecessors, owing, first, to the growth of the staff; secondly, to the incorporation in it of papers from Sudan officials who have for the most part worked from time to time in the laboratories. In addition, Dr. Leiper, Helminthologist to the London School of Tropical Medicine, describes the helminthes collected by Dr. Wenyon, the travelling pathologist for the year; Mr. Theobald writes on new mosquitos from the Sudan; Dr. Werner of Vienna names the reptiles and poisonous snakes of the Sudan; and Dr. Waterston adds an anthropological report on the late Dr. Pirie's work. Besides contributing papers on trypanosomiasis, piroplasmiasis, and spirochaetosis, the Director (Dr. Balfour) and his assistant (Lieutenant R. G. Archibald, R.A.M.C.) give in a supplement a review on some of the recent advances in tropical medicine. Dr. Balfour also gives, in his capacity of medical officer of health, interesting details of the sanitary condition and public health of Khartoum. Sleeping sickness is dealt with by Captain Howard Ensor and Mr. Archibald; kala-azar by Captains Cummins and Bousfield; protozoology by Dr. Wenyon, lent by the London School of Tropical Medicine; economic entomology by Mr. King; chemistry by Mr. Beam; and medical practices and superstitions among the people of Kordofan by Captain Anderson.

Amidst such a very large mass of material, it is impossible here to discuss more than a few points. Dr. Balfour, in his paper on trypanosomiasis, discusses somewhat tentatively a question which has been gradually forcing itself on the minds of those studying these special parasites. Is it justifiable to multiply species of trypanosomes indefinitely as has been done so much of late by Laveran? We say decidedly not, or at least not until there is better proof that they are really different; in this connexion Dr. Balfour notes (page 29) that "Ehrlich, quoted by Browning, does not think that the immunization and subsequent inoculation advocated by Laveran constitutes a sufficient basis." To the open mind it is quite likely that what have been recently termed *Trypanosoma dimorphon*, *T. pecaudi*, *T. soudanense*, and the supposed new trypanosome recently discovered in Zanzibar, are nothing more or less than varieties of or the same parasite as that of "nagana" (*Trypanosoma brucei*, Bruce's original trypanosome).

Another interesting point crops up in Dr. Wenyon's paper, namely, the interpretation of the changes seen in *Leucocytozoon neavei*, and similar parasites. Dr. Wenyon criticizes the description of the leucocytozoon of the

grey hawk of the Congo, given by Dutton, Todd, and Tobey, contending that they have been misled in following Schaudinn, who was mistaken in his idea of the relations of the several parts of the parasite and host cell. There is little doubt now that Schaudinn, hurrying on his work on the development of halteridium, and in some other directions, without controls, fell into some confusion, and did not recognize that he was dealing with several different parasites, instead of stages in the development of one. The tendency to hurry work, often to get it ready for a report, cannot fail to lead to disaster in the future, and Dr. Wenyon must be congratulated on his pluck in exposing these faulty conclusions.

The other papers, which we are compelled reluctantly to pass over, are all very interesting and useful, but note must be made of the frequency of kala-azar in the Sudan revealed in the articles on that subject; this is a very serious matter for the country, and will have to be reckoned with in the future.

The coloured plates illustrating the part dealing with economic entomology are disappointing. Why Mr. Wellcome did not have them done by Mr. Terzi is difficult to understand, especially when the beauty of that artist's work in the second report is remembered. The photographs are numerous and excellent. Dr. Balfour is certainly to be congratulated on his success in getting together such a series of valuable papers, and also on the very good work he has himself done at the Wellcome Research Laboratories.

A prefatory note states that the review of some of the recent advances in tropical medicine, hygiene, and tropical veterinary science, with special reference to their possible bearing on medical, sanitary, and veterinary work in the Anglo-Egyptian Sudan, by Drs. Balfour and Archibald, contained in the supplement, is intended primarily for medical and veterinary officers stationed in the Sudan; it should, however, prove equally useful to doctors in the other African colonies, and, indeed, in other parts of the world. The matter is arranged alphabetically to facilitate reference. Some papers are quoted very fully, others more briefly, and comments are made on several. To review a review is somewhat difficult, but in turning over this supplement we are struck by the amount of repetition of work that goes on with regard to many subjects, no mention being made of the person or persons who made the original observations. In this way not only are time, energy and opportunity wasted, but the secondary work often passes amongst the uninitiated as original, and is quoted as such. A good example of this is the quotation of Lebrede's work (1905) on the development of filariae in mosquitos. As far as can be judged from the abstract there is nothing new in his work, and his histological technique is a copy of that used years ago, and certainly not invented by him. Very much the same may be said about the paper by Ashburn and Craig on the development of a filaria termed by them *Filaria philippinensis* in *Culex fatigans*. There is no proof that this is a new filaria at all; it is the old story retold of the *Filaria bancrofti* developing in *Culex fatigans*. Drs. Balfour and Archibald ought perhaps not to be blamed, since they only quote the papers as recent, and the reader must judge for himself if he has the capability for so doing. The compilation of this review must have cost the authors much labour and time, but they have this to congratulate themselves on—that it will prove an immense boon to many less fortunately situated than themselves as regards the recent literature of the subjects dealt with.

THE executive of the sixth International Medical Congress, which is to meet at Buda-Pesth from August 29th to September 4th, has issued a comprehensive circular giving particulars with regard to the general sittings of the congress and also as to the proceedings of the sections. The lists of papers which it is proposed to read in the twenty-one sections are very long. Six general meetings of the congress to hear addresses will be held: one of these general addresses will be given by Dr. E. F. Balfour, Director of the Imperial Cancer Research Laboratory. The circular again points out that the hotels in Buda-Pesth will not be able to provide sufficient accommodation, and that it is desirable that those who propose to attend should communicate without delay with the Central Travelling Ticket Office, IV Vigadó-ter 1, Buda-Pesth, Hungary; the office of the Secretary-General of the Congress is at Esterházy-utca, 7, Buda-Pesth.

¹ Third Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. By Andrew Balfour, M.D., B.Sc., F.R.C.P. Edin., D.P.H. Camb., Director; Medical Officer of Health, Khartoum. London: Baillière, Tindall, and Cox (for Department of Education, Sudan Government, Khartoum). 1908. (Imp. 8vo, pp. 477, 25s.) Supplement by Andrew Balfour, M.D., B.Sc., F.R.C.P. Edin., D.P.H. Camb., Director, and R. G. Archibald, M.B., B.A., M.D., attached to A. A. Pathologist and Assistant Bacteriologist. (Imp. 8vo, pp. 251, 10s. 6d.)

THE

THERAPEUTIC APPLICATIONS
OF RADIUM:

METHODS AND RESULTS.

THE DESTRUCTIVE REACTION CAUSED BY
RADIUM.

[FROM OUR PARIS CORRESPONDENT.]

The destructive action of radium, employed with a therapeutic object, is well known, for when radium was first introduced this action alone was utilized. It is interesting, therefore, to note that Dr. Wickham tries to avoid this destructive action and to limit the cases in which this destruction is necessary. It has been found that in some cases long, even one or two years, after the treatment has ceased, the new-formed tissues have become the seat of telangiectases, a drawback which must be taken into account.

The destructive power of radium may be employed in those cases in which the aesthetic result is of secondary importance and in which, even if telangiectases supervene, the condition is still superior to what existed previously—cases, in fact, in which a destructive reaction is necessary, and when, as in lupus, radium has no selective specific action. In such a case the lesion is of so grave a nature that, if destruction brings about a cure, the few telangiectatic elements which might ultimately appear would be relatively of no importance.

In such cases Dr. Wickham does not hesitate to use strong doses—apparatus, for example, giving radiations of an activity of 500,000, which he leaves applied for five or six hours at a time. In the same way he does not hesitate to act energetically on pigmented naevi which form tumours.

The degree of the destructive action must be regulated according to the depth at which it is to operate. When superficial action is desired the apparatus is applied without a filtering screen, but to obtain a deeper destructive action a screen of medium absorbent power, from a tenth of a millimetre of aluminium to a tenth of a millimetre of lead, is interposed. By using the lead screen the rays of low penetrating power are cut off; those that remain act more deeply, but it is necessary to leave them in contact for a sufficient length of time to bring about destruction not only on the surface but in all the thickness of the tissue. At Dr. Wickham's clinic, at the Radium Institute, a large and fairly deep rodent ulcer was treated as follows: An apparatus, the utilizable activity of which was 500,000, was covered by a filtering screen of lead 1 millimetre thick; this was left in position for twelve consecutive nights from 7 p.m. to 7 a.m. Only a sharp inflammatory reaction was produced, a thick crust formed, and the entire rodent ulcer was involved in the reaction to the very penetrating radiations. When the crust fell off at the end of three weeks the healed surface was excellent and solid. This was a very good result, for the ulcer had previously resisted other methods of treatment; the cure also was very quick, because fifty days after the treatment was started nothing remained of the ulcer.

Drs. Wickham and Degrais have remarked that destructive inflammations produced in the depths of the tissues by the filtration methods, described in the preceding articles in the BRITISH MEDICAL JOURNAL, were repaired much more quickly than superficial destructions caused by the action of the alpha, soft and medium beta rays of weak-penetrating power.

Whatever destructive process is employed, the action must be carefully regulated to avoid the risk of causing radium dermatitis. When the reaction produced by radium is slight, the skin is sometimes restored to a normal condition; and even when this result is not attained, it is rare to have any depression or retraction, so that the method may be applied to the eyelid, nostril, or lip. The drawbacks are the production of a very smooth, uniform, whitish condition of the surface; the occurrence of pigmentation which eventually disappears; or the late appearance of some telangiectasis. The last is the greatest drawback. It would indeed be of small importance if the cure of cancer was in question, but when it is a question of a flat,

superficial, and not deeply-coloured naevus, it calls for careful consideration.

The following is a very striking example of the good effects of the destructive action of radium treated at Dr. Wickham's clinic:

A girl aged 13 had a large tumour of the class of pigmented naevi filling up the depression between the nose and the cheek. This tumour rose above the ridge of the nose, was of very dark colour, and gave the face a repulsive look. It was necessary to resort to the destructive action of radium in this case, since pigmented naevi are not specifically affected by it. A powerful apparatus was applied without any filtering screen, so that an inflammatory reaction with crust formation ensued. Two months later the inflammation had calmed down and the tumour had diminished by half. Two similar treatments were carried out at two months' intervals. The appearance of the face is now normal, the naso-malar depression is normal, and there is no projection above the surface, which is of the colour of *caffé au lait* with a whitish, smooth, cicatricial appearance in two places. There is no retraction of the eyelid which was affected nor of the nostril, so that the result, on the whole, is excellent.

To produce inflammatory reaction the duration of the applications of radium must be prolonged, and no tissue possesses absolute resistance to the rays. If with an application of duration x a certain tissue has resisted, it is sufficient to make an application of $x + x$ to produce irritation. The great difficulty in radium therapeutics is, in fact, to avoid causing destructive effects and to obtain cures without any, or with the smallest possible, inflammatory reaction.

INTERNATIONAL MEDICAL TEMPERANCE

APPEAL, 1909.

It is proposed to present at the twelfth International Congress on Alcoholism, to be held in July, 1909, in London, an international medical temperance appeal to the rulers, teachers, and clergy of all nations. Many of the Continental countries are already well represented by signatories. The promoters hope that Great Britain and Ireland may not be behindhand in the matter, and ask, therefore, that all who are willing to sign will intimate this fact not later than May 12th to Mr. W. McAdam Eccles, M.S., 124, Harley Street, London, W.

APPEAL TO THE MEDICAL PROFESSION OF ALL
NATIONALITIES.

The International Union of Medical Abstinents, founded at the eleventh International Congress against Alcoholism, held at Stockholm in 1907, invites medical men of all nationalities to unite for common action to break the bonds of alcoholism. This appeal is based upon the following main considerations:

1. Many of the physical ills we have to bear are, and will be, the result of the action of alcohol taken in the form of a beverage.
2. To the medical profession falls the special duty of instructing people on these matters.
3. The consequences of the continued use of alcohol, as shown by the history of the human race, are always the same: demoralization, degeneration of individuals, and decadence of nations.
4. Spirituous drinks of any kind are unnecessary for the healthy individual; a desire for them exists only where it has been created artificially.
5. All normal organisms perform their various functions better without alcohol, which is specially dangerous to young or growing tissues.
6. For the welfare and preservation of future generations it is necessary to discontinue the use of alcoholic beverages, as only by widespread abstinence can alcoholism with its consequences be met and restricted.

On these grounds we members of the International Union of Medical Abstinents call upon our medical brethren of all lands to unite with us in the struggle against alcoholism and to sign the following appeal:

APPEAL FROM THE PHYSICIANS OF ALL COUNTRIES.

To all rulers, Governments, representative assemblies, to all tutors, teachers, clergymen, and to all who have at heart the welfare of our race and of future generations:

We, members of the medical profession, believing that by our studies and opportunities of recognizing and estimating the nature and action of alcoholic beverages, we are qualified to offer an opinion, affirm it as our strong conviction that these beverages are not only unnecessary, but are extremely injurious, and that the evils which arise and are ever breaking out from the consumption of alcoholic beverages can, and must be, eradicated and prevented. We believe that young people especially should receive careful and as full instruction as possible, and should be trained by example, as well as pre-

tected by law, to abstain from the consumption of alcoholic beverages.

We are fully convinced that some such step must be taken in order to create a sober world and to promote and ensure the happiness, welfare, and progress of the human race.

SIR ALMROTH WRIGHT AT THE AUTHORS' CLUB.

On April 26th Sir Almroth Wright was the guest of the Authors' Club at a dinner at which some fifty members and their friends were present. Dr. ROBINSON presided, while Mr. CHARLES GARVIE was Vice-Chairman.

SIR ALMROTH WRIGHT in his speech adapted his language and argument to his lay audience, apparently satisfying the minds of his listeners. Bacteria, he said, played the most formidable rôle in the world. They were responsible for epidemic disease, and some conception of the significance of this might be gained from the fact that 1,200,000 lives were lost last year from plague. Next he dealt with some diseases of which we had already got the better, for example, typhoid fever, small-pox, and others. He regarded the epidemic acute diseases as of comparatively small importance, while the chronic diseases which were due to bacteria were the most serious. The forces which acted in regard to these diseases were not yet under control. After some further remarks of a general character, he made an attack on surgery, with especial reference to bacterial disease, contending that the lopping off of a limb to get rid of an infection was as reasonable as it would be to free a garden of weeds by digging up a few spadefuls of earth from time to time. Drugs came in for their share of condemnation, but an exception in their favour was made in the case of malaria, syphilis, and sleeping sickness. Sir Almroth Wright next turned his attention to Nature's machinery for disposing of bacteria. Lady Mary Wortley Montagu in introducing inoculation of the virus of small-pox early in the eighteenth century, marked the first great step in immunization. Then came Jenner's discovery, and the effect of using attenuated microbes was discussed. The generalization of laws with regard to prophylaxis had marked the work of Pasteur. Lord Justice Fletcher Moulton had suggested that as "prophylaxis" was the word used to mean preventing the disease before

infection, the word "phylaxis" might be applied to that prevention which took place after infection, in which the length of the incubation period was made use of, as in rabies. Phylactic inoculations, however, were two-edged methods, and might be as dangerous as they might be useful. The next step was a comparatively small one. This was to attack a local infection before the bacteria had spread beyond a narrow limit, and the infection had been converted into a general one. He assumed that no one would doubt that local infections could be dealt with by immunizing means. He held that the same law must hold good for severe infections as did for mild infections of a local nature. Without describing the processes which produced immunity in detail, he briefly referred to phagocytosis, and stated that Metchnikoff's original claims in this respect had been disproved. In the fluid portion of the blood were chemical substances which formed part of the machinery of immunization. These substances were well defined, although he believed that the list of them was not yet complete. He dwelt on the function of the leucocyte as the wandering cell which picked up the bacteria and digested them. Having lightly outlined his conception of the natural process of immunization by the chemical substances which acted on the invading bacteria, he turned to his own method of artificially increasing the activity of the processes by means of vaccines. In speaking of the diseases to which this method could be applied he divided infective diseases into three classes. First, there were the acute septicæmic diseases, which either caused death or spontaneously ended in recovery. Immunity resulted as a natural process after the attack. Next, there were the localized infections with constitutional symptoms; and lastly, the localized infections without such symptoms. The process of immunity was not set to work in the latter, as was proved by the fact that lupus might last for forty years. These diseases did not cure themselves. They could not be dealt with by sanitation; they could only be properly treated by means of therapeutic inoculations. In concluding, he said that he believed that this method would be the proper one for the treatment of all diseases.

After some remarks by Dr. ALLEN,

Lord Justice FLETCHER MOULTON gave a layman's description of what nature did when the body was invaded by bacteria. Sir Almroth Wright had not troubled to satisfy the medical profession, and there were many members who differed from him, but he believed that in time Sir Almroth's views would be accepted. The swarms of bacteria appeared formerly to have it all their own way, but now it could be shown that myriads of friends were ready to encompass these enemies. It must have appeared to be almost hopeless to fight these numerous microbes, but inasmuch as they were all alive, it was certain that nature must have some way of doing it. This method must be automatic, or else it could not succeed. Nature had a funny way of pulling us through an infective disease such as typhoid. At first the bacteria were not numerous and the patient was not very ill. But later he became more and more ill, and the bacteria increased, until they literally swarmed; and, just when he might be expected to die, he suddenly got better. Nature did not prepare against invasion until the enemy arrived, which was a method not unknown in political life, but which must appear to be a curious method. It was the coming of the enemy which started the preparation. But nature was blind, even if she felt most acutely. She answered the call even of dead bacteria. In prophylactic measures, the countryside was awakened and fully alive; all the police were called out. In localized disease—that was, when there had been invasions of a small area—there were no policemen, and all the hooligans did what they pleased. Since the local force was beaten, vaccine therapy called out the police of other districts, and as these arrived in their masses the lawlessness was quenched and the invaders were thoroughly routed. The trick of offering nature a dead microbe to induce her to exert her protective forces was clever. The speaker concluded by bestowing great praise on the guest of the evening, and prophesying that vaccine therapy would replace the older methods some day.

Mr. BRUDENELL CARTER and Mr. F. GRIBBLE also spoke and Sir ALMROTH WRIGHT replied.

THE BUDGET AS IT AFFECTS THE MEDICAL PROFESSION.

To the average taxpayer the Budget of 1909 is not a little bewildering. This is due partly to the length and discursiveness of the Chancellor's speech—the delivery of which occupied no less than four hours and a half—and partly to the numerous additions which are to be made this year to direct and indirect taxation in order to provide for the huge and, in time of peace, unprecedented increase in the national expenditure. It will probably interest our readers if we attempt to unravel the skein, and to show how far the proposals of the Chancellor of the Exchequer affect medical practitioners, either directly as a class or indirectly as ordinary citizens.

INCOME TAX.

As for the income-tax proposals, so many members of the profession are affected by them that it may be well to explain briefly their purport and effect. By the successive introduction of a scale of abatements, differentiation between earned and unearned incomes, and now a supertax on large incomes, the calculation of the amount of income tax payable by any individual has become a somewhat complicated problem, which a change in the general rate of tax does not help to solve. The following tabular statement shows in the briefest form the effect of the proposals for the current year:

Amount of Total Income.	Abatement Allowed.	Rate of Tax Payable if the Income is—		
		Wholly Earned.	Wholly Unearned.	Partly Earned and Partly Unearned.
£ 160-400	£ 160			
400-500	150	9d.	1s. 2d.	9d. on earned and 1s. 2d. on unearned portion.
500-600	120			
600-700	70			
700-3,000	—	9d.	1s. 2d.	Ditto
2,000-3,000	—	1s.	1s. 2d.	1s. on earned and 1s. 2d. on unearned portion.
3,000-5,000	—	1s. 2d.	1s. 2d.	1s. 2d.
Over 5,000	3,000 at 6d. in the £	1s. 8d.	1s. 8d.	1s. 8d.

A few observations may be made in further explanation of the foregoing table. With regard to total incomes not exceeding £700 the appropriate abatements are allowable primarily from the assessment on the earned income—that is, at the ninepenny rate, and from the unearned income only to the extent, if any, to which the earned income is insufficient to permit the full allowance to be made therefrom. A few examples will make this point clearer:

Amount of Income.			Abatement Allowable.	Net Amount Taxable.	
Earned.	Unearned.	Total.		At 9d.	At 1s. 2d.
£ 200	—	£ 200	£ 160	£ 40	£ —
160	160	320	160	—	160
100	200	300	160	—	140
80	600	680	70	10	600

The placing of the limit of differentiation in favour of earned income at £3,000 was recommended by the Income Tax Committee of 1906, but this recommendation was not adopted in its entirety by the then Chancellor of the Exchequer when framing his Budget of 1907, the relief granted on earned incomes stopping at £2,000. Mr. Lloyd-George has now extended the relief to incomes not exceeding £3,000, but limits it by imposing a higher rate—namely, 1s., on incomes lying between £2,000 and £3,000, instead of 9d., the rate chargeable on earned incomes not exceeding £2,000. All relief on earned income ceases when the total income exceeds £3,000, and from £3,000 to £5,000 the general rate of 1s. 2d. applies to all classes of income alike. When the total income

exceeds £5,000 a supertax of 6d. in the £, over and above the normal rate of 1s. 2d., is to be imposed, the additional tax to be collected by means of a direct assessment on the person liable. This supertax is not to be charged on the total income, but every person liable is to enjoy an abatement of £3,000, and to pay supertax on the excess beyond this amount. Thus, an income of £5,001 will pay 6d. in the £ on £2,001, one of £10,000 will pay on £7,000, and so on.

Before leaving the subject of supertax it is desirable that a misapprehension which has caused needless alarm to many persons should be removed. It has been assumed that the supertax will apply not only to the incomes of individuals, but also to those of firms, companies, societies, etc., and fears have been expressed that the owner of a few shares in, say, a railway company, might in this way be made to bear a share of the supertax. This is a mistake. The Chancellor of the Exchequer has recently stated specifically that the supertax is to apply only to the incomes of individuals, and not to joint-stock companies and other bodies of persons.

This statement is of particular interest to medical practitioners who are carrying on business in partnership. Suppose, for instance, that the profits made by a firm of three persons amount to £5,400, and that each partner takes one-third of the total, and has no other income. Although the total profits exceed £5,000, the share of each partner, which, in this case represents his total income, is under that amount. In these circumstances not only will no supertax be payable, but each partner will be able to claim the benefit of the ninepenny rate, as his total income is less than £2,000. The rule is that the profits of a partnership must be assessed in one sum, but that the rate of tax to be charged on such profits depends on the respective total incomes of the individual partners among whom the profits are divided.

An unexpected but welcome feature of the Budget income-tax proposals, to which reference has not yet been made, is the allowance of abatements for children. These abatements will be granted only to persons whose total incomes do not exceed £500 a year, but subject to this limitation, it is proposed to make an allowance of £10 (tax, at 9d., 7s. 6d.) from the assessment, for every child under the age of 16 years. The effect will be that, together with the ordinary abatement of £160, one child will free an income of £170 from tax, four children will free an income of £200, and eight children one of £240. As this abatement is to be made in addition to all other allowances, a case may possibly occur of a person with an income of £300 having nine children, and paying £50 a year for life assurance premiums, who will be called upon to pay no income tax at all. It may be of interest to note in passing that abatements for children were allowed in Pitt's income tax of 1799. Mr. Lloyd-George's proposal, therefore, has not the merit of novelty.

MOTOR CARS.

In lieu of the existing licences the owners of motor cars are in future to pay according to a graduated scale, ranging from £2 2s. on cars of less than 6½ h.p. to £42 on cars above 60 h.p. "Doctors' cars," said Mr. Lloyd-George, "I propose to charge at one-half these rates," and few persons will be disposed to question the fairness of this differentiation in favour of the profession. The Chancellor also announced a tax of 3d. a gallon "on all petrol or spirits used for motor vehicles," with a rebate of one-half in the case of commercial vehicles. No special mention of the doctor was made in this connexion, and it is doubtful whether he is to be regarded as entitled to the rebate. As, however, the ground for charging him with licence duty on his car at half rates is that he uses it for the purposes of his profession, it would be highly anomalous if the petrol were regarded as used for other than "commercial" purposes.

In endeavouring to estimate the effect of the new tax, which for the purpose of calculation has been taken to be levied at the higher rate (3d.), the factors to be considered are the average distance travelled by the medical man every year, the average rate of fuel consumption by his car per completed mile, and the skill of its driver. As regards the first of these points, a distance of 5,000 miles is commonly assumed to be the mileage traversed by an average medical man in the course of his professional

duties. It represents about 16 miles a day, not including Sundays, and probably therefore does not err on the side of excess.

The amount of fuel required by engines varies very considerably with cars of different makes, and also of course with the horse-power employed. A car, however, of good make and not exceeding about 8 horse-power ought to travel at least 25 miles for every gallon of petrol, and as the majority of medical men who use cars strictly for professional purposes do not buy high-powered cars, an engine of this character is sufficiently illustrative. Of course, high-powered engines consume much more petrol than small cars, and there is no absolute ratio between horse-power and fuel consumption, even in cars of the same make; nevertheless, it may be assumed, for practical purposes, that if an 8-h.p. car of a certain make will travel 25 miles on one gallon, a 20-h.p. car of the same make will travel about 18.

Every item of expense involved by the use of automobiles is liable to be increased by unskilled driving, and fuel consumption is no exception; nevertheless the effect of bad driving is relatively so small that this factor may be left out of consideration and the additional expenditure entailed by the increased duty be put down as about £2 10s. in the case of users of quite small cars, and as about £3 3s. in the case those who use cars of between 16 and 20 h.p. It appears, however, to be intended to collect the tax not from the retail purchasers of petrol, but from the wholesale importers, and it is anticipated that these will increase the retail charges not merely by 3d., but by 4d. or 5d. so as to cover the expense in the way of bookkeeping and capital outlay in which it is alleged they will be involved. Hence the expense to medical automobilists will be considerably higher than the sum just stated, the figures being thus raised to about £3 10s. in the first case, and upwards of £4 4s. in the second. In other words, the price of petrol will rise from the low figure to which it has dropped during the last year or two to that at which it stood when motor-car driving first became at all general.

Medical automobilists have hitherto been taxed partly under the Inland Revenue Act, and partly under the Light Locomotive Act, the precise amount they pay being determined by the weight of the car they use. The new proposal is that the cost of a licence shall depend not on the weight but on the horse-power of the car to which the licence applies, the scale being as follows:

	£	s.	d.
Cars under 6½ h.p.	2	2
" " 12 h.p.	3	3
" " 16 h.p.	4	4
" " 26 h.p.	6	6
" " 33 h.p.	8	8
" " 40 h.p.	10	10
" " 60 h.p.	21	0
" over 60 h.p.	42	0

Medical automobilists will pay half these rates, but what these rates will work out to in the case of any given car is not easy to determine. Since one horse-power is merely a capacity to raise a weight of 33,000 lb. one foot in one minute, it seems at first sight as if it should be sufficiently easy to determine the horse-power of any given engine; but in practice this is by no means the case, and such numerous methods of calculating horse-power have been devised, that at present the term "horse-power" tends to be somewhat vague. Inasmuch as purchasers are usually prepared to pay heavier prices for high than low-powered vehicles, the tendency of vendors, if not of manufacturers, has perhaps been to exaggerate the power of the cars of which they have to dispose; but on the other hand, in the case of cars of the class whose claims have always been advocated in these columns, namely, those which have figured well in the reliability trials of the Royal Automobile Club, the horse-power in the case of small cars is commonly under rather than over estimated, owing to the club's rules in respect of trials. What method of estimating horse-power will be adopted for revenue purposes remains to be seen, but there is reason to believe that it will be that of the club in question. Its method has been reduced to the formula:

$$D^2N = H.P.$$

in which the divisor 2.5 is a constant, D the diameter of the cylinder, and N the number of cylinders. In the case

of a car with four cylinders, each 4 in. in diameter, the calculation would be:

$$\begin{aligned} H.P. &= 4 \times 4 \times 4 \times 0.4 \text{ (which equals } \div 2\text{)} \\ &= 64 \times 0.4 \\ &= 25.6 \end{aligned}$$

and such a car would be classed as under 26 h.p.

It has been objected that this formula leaves out of consideration the length of the piston stroke; but this is not truly the case, because it is based on the power output of normally-proportioned engines, and departures from the normal in point of stroke length are accompanied by so many disadvantages that in the long run they will not be adopted. The actual power of an engine may be increased by adding to the length of its stroke, but such increase causes jerkiness and vibration, and the aim of all constructors of high-powered cars is to eliminate vibration, and thereby increase comfort. On the other hand, abnormal length of piston stroke is not uncommon in small cars, because manufacturers desire to make them as speedy as possible in proportion to their size, and their users are prepared to put up with a certain amount of vibration. Hence it may very well be that those who possess cars of 10 to 16 h.p. may be pleasantly surprised when their cars come to be measured for revenue purposes.

In any case it would not appear that many medical automobilists are likely to pay more in the way of car licences under the new arrangement than under the old, and many of them may pay less. A car of 10 or 12 h.p. commonly weighs from 11 to 15 cwt., and the owner at present pays £2 2s. In future he will pay only 31s. 6d., or less than at present: while those using 16-h.p. cars will only pay the same amount as the driver of a brougham or victoria—namely, £2 2s. Above 16 h.p. the rise in the tax is considerable, but even those who own cars over 20 h.p. will only pay a guinea more than now.

OTHER IMPOSTS.

The death duties are to undergo revision, and the estate duty on all estates exceeding £5,000 will be considerably increased, estates of £1,000,000, and upwards paying the maximum rate of 15 per cent. Stamp duties on the transfer of real property will be doubled, and certain other stamp duties will be considerably increased. Taxes on spirits are to be increased by 3s. 9d. a gallon, and the tax on tobacco is to be raised 8d. a pound. Moreover, a beginning is to be made with a sweeping measure of land taxation. This proposal provides for three separate but connected taxes, namely, a duty of 20 per cent. on future appreciation in the capital value of land, a reversion duty payable when leases fall into possession, and a duty on undeveloped land. These imposts will directly affect the medical practitioner only in so far as he may be the owner of property and in his work of making provision for any family he may leave behind him. They are, however, capable of almost unlimited extension, and may ultimately lead to the shifting of the burden of local rates and Imperial taxes from houses and buildings to the land or sites on which they stand. It will be time enough to deal with this aspect of the question of land taxation when these wider proposals are about to become an accomplished fact.

It is somewhat unfortunate, too, that Mr. Lloyd-George, in his eagerness to find a "new hen-roost to rob," should have imposed an additional duty of 3s. 9d. per gallon on proof spirit, an increase which will materially affect the price of many medicines, especially tinctures. The matter is, we believe, under consideration of pharmacists' associations, who consider that the manufacture of medicine should be subject to a special rebate. The increase in the cost of medicines will, as is pointed out by a correspondent, make contract medical practice at anything like present rates all but impossible. In this, as in other ways, although the Budget has a socialistic basis, it is the poor on whom the burden of the new taxation will ultimately fall.

AN OMISSION.

In conclusion, we regret that in framing his Budget the Chancellor of the Exchequer has not availed himself of the opportunity to impose a tax on patent medicines of a much more onerous character than the existing impost. In our judgement there could scarcely be a fitter subject for taxation, while the enormous quantities of such medicines which are sold annually render it certain that

the Revenue would benefit considerably from such a tax. Mr. Lloyd-George, however, has elected to go elsewhere for his money, and it now remains for him only to obtain the consent of Parliament to his proposals for them to become law.

EGYPT AND THE SUDAN IN 1908.

The reports of Sir Eldon Gorst, British Agent and Consul-General, on the finances, administration, and condition of Egypt and the Sudan in 1908, were issued on May 4th. In the opening passages the administrative difficulties caused by the agitation against the British occupation are discussed, and must be borne in mind in estimating the rate of progress.

EGYPT.

The growth of the population of Egypt is greater than that of most European countries, with the exception of Germany, and exceeds that of India. The population enumerated by the census was 11,189,978; nomad Arabs could not be enumerated, but an estimate obtained from their chiefs placed their number at 97,381, giving a total population of 11,287,359. The growth of the population in Cairo and Alexandria has been specially rapid.

The project for the drainage of Cairo recommended by Sir William Garstin, formerly adviser to the Ministry of Public Works, and by the Director-General of the Public Health Department, has been approved, and the works will, it is anticipated, be commenced at an early date, but will take some years to complete. With regard to the water supply, a simple method of removing iron and manganese from the Rod-el-Farag supply has been found efficient, but the water still remains much harder than that of the Nile. The discussion on this point and also as to the permanence of the supply and its protection from pollution is still proceeding.

Hospitals.

The twenty-one general hospitals in Egypt contain 2,153 beds; the in-patients in 1908 numbered 33,241, an increase of a little more than 2,000 on the previous year. There were 181,580 out-patients, an increase of over 16,500. In order to bring medical aid within the reach of the more remote villages, the sanitary department is gradually instituting fully-equipped dispensaries and first-aid establishments under the direction of the local medical officer. There are now 48 such dispensaries, and the total number of patients attending them in 1908 was 38,000, an increase of 30 per cent. over the previous year. The wealthier inhabitants continue to show their interest in the foundation of hospitals, and during the year a considerable sum was subscribed to endow a hospital at Mellawi, in Upper Egypt.

EGYPTIAN OPHTHALMIC HOSPITALS.

The travelling ophthalmic hospitals instituted through the generosity of Sir Ernest Cassel have now become a branch of the Public Health Department. The number of patients treated during 1908 was 7,764, but 10,445 were refused on account of lack of accommodation. Sir Eldon Gorst considers it very desirable to institute an organized system for the examination of the eyes of school children, and calls attention to the statement of Mr. MacCallan, Chief Inspector of Ophthalmic Hospitals, that in one school he visited 22.6 per cent. of the pupils had their eyesight permanently depreciated, while 37.5 per cent. had such defective vision that they were unable to attain even the low standard required for admission to the clerical ranks of the Egyptian Civil Service. The permanent eye hospital at Tanta was opened last November. At Assiout the inhabitants have subscribed £E5,000 for the construction of an eye hospital, and at Mansourah a local notable has given £E5,000 for a similar purpose. The Government has undertaken to maintain all hospitals constructed by private subscription.

Lunatic Asylums.

The extension of the Abbassieh Asylum was continued, and a new prisoners' block, a female section, and other minor additions will be ready for use this year. Eventually the asylum will provide accommodation for 1,100 inmates. The asylum in the course of erection at Khanka, intended to be an agricultural settlement for chronic and mild cases, will, it is hoped, be ready in two or three years

to receive 300 inmates. Among the patients admitted to the Abbassieh Asylum, hashish was assigned as the cause of insanity in 8 per cent., as compared with 14 per cent. in the previous years. The police displayed considerable zeal in raiding hashish dens, gambling houses, and unlicensed liquor shops, and as a result 1,908 establishments where hashish was used were definitely closed, and it would appear that an efficient coastguard service, which is at the present time almost entirely occupied in preventing the smuggling of hashish, coupled with strict police measures in the towns, has materially limited the opportunities for indulging in this lamentable habit.

Plague and Cholera.

The number of cases of plague was 1,511, distributed over 142 centres of infection; the corresponding figures for 1907 were 1,253 in 107 centres. The infection was introduced nine years ago, but until 1906 was practically confined to the Delta and Middle Egypt and was of the bubonic form. When Upper Egypt was invaded the disease took the very fatal pneumonic form. Special measures were organized in the four southern provinces dealing with the outbreaks, and wherever early information was obtained cases were quickly controlled, as a rule within the limit of the period of incubation, but in villages where the occurrence of the disease was concealed much more energetic action was necessary. The most difficult task of the officers of the sanitary department is to overcome ignorance and prejudice with regard to giving early information.

Only a few cases of cholera occurred in the quarantine camp at Tor; Egypt itself was not invaded.

Village Barbers.

On this subject Sir Eldon Gorst makes the following observations:

The office of village barber is an institution of great antiquity in Egypt. Without going into this functionary's history, it may be said that his duties consist principally in performing vaccination and various minor operations, sending in returns of births and deaths, and furnishing other information to the district authorities. He obtains no remuneration from the Government, but receives small fees from his clients, and his interests are closely bound up with the goodwill of the village Omdeh. The functions and responsibilities which he exercises have not contributed to independence of character, or to a sense of duty to the superior authority which would be furnished but does not pay him. The rank and file of this class are consequently of indifferent quality, and really trustworthy men are few and far between. Last year the experiment was made of utilizing the village barbers in connexion with the special measures for dealing with pneumonic plague in Upper Egypt, and a small sum was devoted to paying a few selected barbers in each province, in order to obtain more speedy and trustworthy information than would be furnished by the villagers, and to encourage the early notification of suspicious deaths or illness in the barber's village or its neighbourhood. In most cases the offer of a small fixed salary was sufficient to obtain all that was required. Reports from the provincial authorities are unanimous in testifying to the advantage of the system, and in recommending its further extension on a permanent basis. It must be admitted, however, that, apart from financial considerations, the general mass of the barbers are not as yet worthy to be taken into the Government service. The majority are illiterate, many are inefficient, and in some cases men of indifferent character have been appointed, in the absence of more desirable candidates.

Egyptian University.

The Egyptian University was inaugurated by the Khedive in December last. The chief practical objects to which its efforts are at present directed are to form a professorial body capable of lecturing in Arabic on the principal sciences taught in Europe, and to bring before the Egyptian public the latest developments of science and literature in Europe. Of the 754 students originally entered 678 were Egyptians, of whom 503 were Mohammedans; among the students were 31 women. The income of the university during the year was £E27,000, of which amount £E16,000 was provided by private generosity.

School of Medicine.

During the past year 50 students joined the school, and 7 obtained their diplomas—4 in medicine and 3 in pharmacy. There are now 190 students in attendance. Owing to this large increase, the staff finds great difficulty in carrying on the work efficiently, and when the next budget is prepared this question will require careful consideration.

In 1903 two graduates of the school were sent to England to be trained as assistant professors, and arrangements were made for sending two others early this year. The importance of exercising great care in the choice of men who are to be trained in Europe at Government expense as future teachers at the School of Medicine is self-evident. The safest method it is considered is to test the most promising at laboratory work before a definite selection is made, and thus to make certain of their possession of such essential qualifications as the power to exercise authority over students, willingness to accept responsibility, and desire to acquire knowledge for its own sake.

SUDAN.

Though during 1908, the tenth year of the reoccupation of the Sudan, there has been unrest among the tribesmen, and fresh proof that Mahdism as a faith is not extinct, and in spite also of a deficit in the revenue, there is evidence of increasing prosperity. The population of the country is not known, but the significant fact is mentioned that the number of children of 10 years and under is very large, whereas there are comparatively few youths and girls between the ages of 10 and 20; this is held to prove that the inhabitants are naturally prolific, and that a period of continued peace will repair the ravages made by war and pestilence.

Public Health.

The Sudan was free from any serious epidemic of infectious disease during 1908, but Dr. Christopherson reports minor outbreaks of cerebro-spinal meningitis, infectious pneumonia, small-pox, chicken-pox, diphtheria, and dengue, and there have also been isolated cases of kala-azar, Malta fever, and blackwater fever. At least 5 cases of kala-azar have been treated in the Khartoum hospitals, and Sir Eldon Gorst records with regret the death of Captain Craik from this disease. A medical officer is to study the disease in Kassala, where most of the cases have originated.

The number of in-patients treated in all the institutions in the Sudan was a little over 7,000—about the same as last year. The number of out-patients was 121,214, an increase of over 27,000 as compared with the previous year. The new hospitals at Port Sudan and Atbara are practically completed, and the new Khartoum Hospital will be ready for occupation during the present year. Dr. Christopherson considers that attempts to train native women in nursing have so far proved a failure, and that Arab and Sudanese boys make better hospital attendants.

The system of selling quinine at the post-offices seems to be appreciated, as over 6,000 boxes were sold during the year.

LITERARY NOTES.

A MEETING of the Council of the Italian Society of the History of Medicine and the Natural Sciences was recently held in Rome. It was decided that the proceedings of the Congress of the society held at Faenza should be printed. This year the society will hold its annual meeting at Venice.

At the prize distribution to the 2nd Home Counties Field Ambulance Royal Army Medical Corps commanded by Major A. R. Henchley, for their first year's work under the new territorial scheme, on Easter Monday, the Mayor of Canterbury referred to the part taken by East Kent in national defence in former days. He said that in the days of the Armada, the levies of East Kent were hastily assembled at Northbourne. The city of Canterbury sent 200 of her own soldiers with twenty trained shot, all fully equipped at the city's expense, and led by one of her own aldermen. The records might still be read in the old Corporation books how the city also ordered new drums and two new "ensigns" of the old city colours, red and white, at the public charge of several pounds. It is interesting to note that the next heaviest payment was for unguents for the surgeon of the company and a "goodly chest to bestow his instruments of surgery." Fortunately they were not required, but it was probably not generally remembered, even in Canterbury, that it was this particular array which Macaulay had in his mind in his famous ballad of the Armada:

With loose reign and bloody spur rode inland many a post.
With his white hair unboughtened the stout old Sheriff comes.
Behind him march the halberdiers, before him sound the drums.

Later it was recorded that during the wars in the Low Countries Dr. John Golder charged £44 5s. for attendance on 42 English for 59 days, and the apothecary charged £83 18s. 7d. for medicines advised by Major Henchley's predecessor of that period.

H. K. Lewis has in preparation a new book entitled *Immunity and its Applications in the Diagnosis and Treatment of Infectious Diseases*, by Dr. D'Este Emery, the author of *Clinical Bacteriology and Haematology*, a work which has reached its third edition in Lewis's Practical Series. The book aims at giving a clear outline of the main facts and theories in regard to immunity, and is not written in support of the view of any particular school. It is intended mainly for students commencing the study of the subject, or for practitioners wishing to learn the scientific basis and exact mode of application of the modern methods of diagnosis and treatment of the infectious diseases. The book also contains a Glossary of Terms—a very important feature in view of the new vocabulary which the study of the subject has called into existence—and an extensive Bibliography. The same firm has almost ready for publication the lectures delivered at the University of London in February, 1909, by Dr. Louis C. Parkes, under the trust of the late Sir Edwin Chadwick. The official title of the course was "The Medical Aspects of Recent Advances in Hygiene as connected with Sewering," but Dr. Parkes has called the book *House-Drainage, Sewerage, and Sewage Disposal in Relation to Health*. Mr. Lewis has just issued a fourth edition of *Binnie's Operative Surgery*. The section on the extremities has been omitted, but in spite of this the revisions and extensions increase the number of pages and the illustrations as compared with the third edition.

Messrs. Rebman Ltd. will publish this month a work entitled *Progressive Creation*, by the Rev. Holden E. Sampson. It deals with the origin of life, of being, of nature and forms, of evil, and of the earth and heavenly bodies, as to which the author is said to propound a new theory.

The *Journal of Pharmacology and Experimental Therapeutics* is the title of a new periodical issued by the Williams and Wilkins Publishing Company, Baltimore. The editor is John J. Abel, Professor of Pharmacology in Johns Hopkins University, with the following as associate editors: A. C. Crawford, Pharmacologist, U.S. Bureau of Animal Industry; C. W. Edmunds, Professor of Materia Medica and Therapeutics, University of Michigan; D. L. Edsall, Professor of Therapeutics and Pharmacology, University of Pennsylvania; S. Flexner, Director, Rockefeller Institute for Medical Research; R. A. Hatcher, Professor of Pharmacology, Cornell University Medical College; C. A. Herter, Professor of Pharmacology, Columbia University; Reid Hunt, Chief of Division of Pharmacology, U.S. Public Health and Marine Hospital Service; A. S. Loevenhart, Professor of Pharmacology, University of Wisconsin; S. J. Meltzer, Head of Department of Physiology and Pharmacology, Rockefeller Institute for Medical Research; Franz Pfaff, Professor of Pharmacology, Harvard University; A. N. Richards, Professor of Pharmacology, North-western University; Torald Sollmann, Professor of Pharmacology, Western Reserve University; G. N. Stewart, Professor of Experimental Medicine, Western Reserve University; C. B. Wallace, Professor of Pharmacology, University and Bellevue Hospital Medical College. The journal will be carried on with the collaboration of the members of the recently organized Society for Pharmacology and Experimental Therapeutics. At least six numbers of the journal will be issued yearly, and will constitute a volume of not less than six hundred or more than six hundred and fifty pages. Among the papers that will appear in early numbers of the journal are:—John J. Abel and L. G. Rowntree: On the pharmacological action of some phthalins and their derivatives, with especial reference to their behaviour as purgatives. A. C. Crawford and H. V. Honn: Some convenient laboratory apparatus. G. Dock: Observations on the effect of ipecac on intestinal amebae. C. W. Edmunds and W. W. Hale: Studies in tolerance: nicotine, lobeline, and strychnine. W. W. Ford: On the toxicity of *Amantia spreta*, *A. strobiliformis* and other *Amantia* whose toxic properties have remained undetermined. W. W. Hale: The effects of caffeine and sodium bicarbonate upon the toxicity of

acetanilide. A. S. Loevenhart and W. E. Medical News.

DR. JAMES MACLACHLAN, Provost of Dornoch, has been for the third time re-elected Chairman of the Licensing Court of the County of Sutherland.

THE first of the course of eight lectures on the structure and functions of the central nervous system in the Physiological Institute of University College, by Dr. W. Page May, will be given on Tuesday next, at 5 p.m., and will be continued on subsequent Tuesdays. The lectures are open to students of the University of London and to qualified medical men on presentation of their card.

At the meeting of the Zoological Society of London on April 27th Mr. R. H. Burne, F.Z.S., exhibited a series of specimens from the Museum of the Royal College of Surgeons, showing (1) the different mechanisms for the movement of the nictitating membrane, (2) the coarse anatomy of the *Tapetum lucidum*, and (3) the organ for elevating the eyes in the plaice.

At a general meeting of the Medico-Psychological Association to be held at 3 p.m. on Tuesday, May 18th, at 11, Chandos Street, London, W., a resolution will be proposed expressing the view that legislation to amend the Inebriates Act is urgently necessary. Dr. John Turner will report his observations on the blood pressure and vascular disease in the female insane.

PROFESSOR TAAV. LAITINEN, M.D., Professor of Hygiene, and Director of the Hygienic Institute in the University of Helsingfors, and Chairman of the Finnish National League of Health, will deliver the Third Norman Kerr Memorial Lecture on July 20th in the lecture theatre of the Victoria and Albert Museum at 8 p.m. The subject will be "The Influence of Alcohol on Immunity."

THE Lord Advocate, the Right Hon. A. Ure, K.C., M.P., will take the chair at the dinner of the Glasgow University Club, London, at the Trocadero Restaurant, on Tuesday, May 25th. Members who intend to be present or to introduce guests are requested to give notice as early as possible to the honorary secretary, Mr. W. Craig Henderson, 2, Paper Buildings, Temple, E.C.

At a provincial sessional meeting of the Royal Sanitary Institute, to be held at the Guildhall, Norwich, on Saturday, May 22nd, at 11 a.m., Mr. A. E. Collins, City Engineer, will open a discussion on the special features of the Travis hydrolic systems of sewage tanks constructed for Norwich. In the afternoon visits will be paid to the isolation hospital and to the sewage tanks.

THE annual meeting of the Invalid Children's Aid Association will be held, by kind permission of Lord and Lady Newlands, at 16, Grosvenor Place, S.W., on Tuesday, May 25th, at 3 p.m. Field Marshal Lord Grenfell will preside, and the Bishop of Stepney, Sir Alfred Fripp, Mr. How, and Miss Tita Brand will be among the speakers. Tickets of admission can be obtained on application to the Secretary at 69, Denison House, Vauxhall Bridge Road, S.W.

A BILL has been introduced into the New York State Legislature providing for the appointment of a board of inebriety for the City of New York and the establishment of an inebriate hospital, with an industrial colony, in which persons arrested for intoxication may be detained and scientifically treated. The measure was framed by the standing committee on hospitals of the State Charities Aid Association.

THE eleventh meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act was held at the Privy Council Office on May 5th. Mr. Almerio W. Fitzroy, the Clerk of the Council, presiding. Evidence was tendered on behalf of the British Medical Association by Mr. J.

Smith Whitaker, M.R.C.S., L.R.C.P., Medical Secretary of the Association; Mr. C. E. S. Flemming, M.R.C.S., L.R.C.P., Bradford-on-Avon; Dr. L. S. McManus, Wandsworth; and Mr. J. H. Taylor, M.B., Salford.

THE International Tuberculosis Society, the President of which is Professor Lancereaux, offers a number of prizes for essays on tuberculosis. One prize is of the value of £12, another of £5, and two of £2. The society also offers two gold, and three silver, medals, each with a diploma of honour. The awards will be made in May, 1910. The competition is open to persons of all nationalities. Essays must be sent in a sealed envelope to Dr. Georges Petit, General Secretary of the Society, 51, rue de Rocher, Paris, before January 1st, 1910.

DR. J. BISSET-SMITH, who is leaving Ashton-under-Lyne after practising there for over thirty years, was recently presented with a testimonial consisting of an illuminated album and a gold watch with chain and pendant, the watch being suitably inscribed; a silver purse and card case combined was at the same time presented to Mrs. Bisset-Smith. Councillor John Wilson said that Dr. Bisset-Smith's work in connexion with educational institutions, town council, police, and infirmary, was well known.

THE annual general meeting of the Poor Law Medical Officers' Association of England and Wales will take place on July 6th, at the Guildhall, London, and a conference will there be opened on the report of the Royal Commission with regard to Poor Law medical relief. The Lord Mayor has promised to open this conference at 11 a.m. in the Council Chamber of the Guildhall. All Poor Law medical officers in England and Wales are invited to attend, and the Honorary Secretary will be glad to hear from any desiring to read papers at this conference. Abstracts of such papers should be sent to the Honorary Secretary, Dr. M. Greenwood, 243, Hackney Road, London, N.E.

THE sixth annual report of the Knightwick Sanatorium of the Worcestershire Association for the Prevention of Consumption shows that this institution has now accommodation for 30 patients—16 men and 14 women—a number still below the requirements of the county; during the year 103 patients were treated. It is a significant fact that 20 per cent. of the candidates for admission were rejected by the medical referees as unsuitable, owing to the advanced or extensive nature of the disease. The results of the six years' work since the sanatorium was opened are satisfactory, in that of the early cases treated 88 per cent. remain in good health and 85 per cent. are at work.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on April 16th. Dr. de Havilland Hall in the chair. The records of the business during the spring show as usual a large number of sickness claims, but though very numerous they have been nearly all of short duration, and the total sick pay disbursements have accordingly not much exceeded the amount expected. The principal business of the committee was the examination of the drafts of the quinquennial valuation and the annual report. The figures of the latter show that the business of the society during the year 1908 was very satisfactory, a large increase having been made both in the number of the members and in the financial reserves. Prospectuses and all other particulars can be obtained on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

At the meeting of the Royal Meteorological Society on April 21st, Mr. Baldwin Latham, M.Inst.C.E., read a paper on percolation, evaporation, and condensation, giving the results of his observations at Croydon during the last thirty years. Two percolation gauges were used, both exactly a superficial yard in area: each contained a cubic yard of natural soil, one of chalk and the other of gravel. The average annual amount of percolation through the chalk gauge was 10.84 in. and through the gravel gauge 10.34 in. The average yearly rainfall was 25.46 in. It appeared that the rate of percolation was governed by the rate of rainfall, for when once the gauges had become sensitive by being thoroughly wetted, the rate at which rain percolated depended entirely on the quantity of rain immediately falling. The evaporator used for determining the evaporation was a floating copper vessel 1 ft. in diameter supported by a life-buoy ring, connected by four arms with the evaporating vessel, the whole being floated in a tank 4 ft. internal diameter containing about 3 ft. depth of water. The average annual amount of evaporation by this gauge was 18.14 in., and the average amount of condensation was 0.36 in.

British Medical Journal.

SATURDAY, MAY 8th, 1909.

OPHTHALMIA NEONATORUM.

It will be remembered that at the annual meeting of the British Medical Association in Exeter in 1907 the Section of Ophthalmology, having discussed a paper by the late Mr. Simeon Snell, relating the results of an inquiry into the cause of blindness in 350 inmates of a blind school, adopted a resolution expressing the opinion that the time had come for the British Medical Association to take action for the prevention of ophthalmia neonatorum. The Council of the Association accordingly appointed a special committee to investigate and report upon the subject, and subsequently, upon the recommendation of the committee, asked the Ophthalmological Society, the Royal Society of Medicine—through its Sections of Medicine and Gynaecology and Diseases of Children—and the Society of Medical Officers of Health to appoint additional members, while at the same time the co-operation of the Central Midwives Board was invited. The committee thus constituted, consisting of representatives of ophthalmology, obstetrics, public health, medicine, surgery, and pathology, with Mr. Sydney Stephenson as chairman, has presented a valuable and voluminous report, which with its appendices is published in the SUPPLEMENT for this week.

It will be at once seen in what a painstaking and thorough manner the committee has discharged its duties. Medical practitioners and well-trained nurses will not need to have pointed out to them that ophthalmia neonatorum is a terrible scourge, which even now accounts for upwards of 10 per cent. of all cases of blindness in this country, while at least one-third of the inmates of blind schools are there because of this disease. In spite of facts of this kind which have been published from time to time in the reports of institutions for the blind appearing in the daily press, the greatest ignorance still prevails among the general public. The committee will deserve the gratitude of the nation if it succeeds in making widely known the deplorable results which ensue when the disease is improperly or inadequately treated.

There can be no doubt that the first recommendation of the committee—to the effect that ophthalmia neonatorum should become a notifiable disease—ought to be carried out, for not only would it lead to proper treatment of cases occurring in the practice of midwives, but it should educate the local sanitary authorities to recognize that the malign influence of the disease is not one whit less grave in its social effects than that of many of the maladies now included in the list.

How often do we hear it said with justifiable admiration and pride that an elderly person has had sight restored through the successful removal of a cataract, for this is one aspect of blindness which specially appeals to the lay mind, although it only means that a person whose life is well-nigh spent is enabled to see for the few more months or years which remain. Of how

much greater importance is it for a child on the threshold of life to be saved from spending the whole of it in a world he has for ever been debarred from seeing! Every set of figures, no matter from what source they are collected, shows that ophthalmia neonatorum is responsible for a great number of cases of blindness, and the profession and the public alike must realize that it is a disease particularly amenable to treatment if only appropriate remedies are applied in time. Once let that short time pass and all may be lost.

The late President, whose death we have so recently had to deplore, and who was a distinguished member of this committee, found that in the Sheffield School for the Blind no fewer than 42.36 per cent. of the inmates were there from the direct results of this disease. In the London County Council schools for the blind Mr. Bishop Harman found that 36.36 per cent. of the pupils had lost their sight from ophthalmia neonatorum; and, as he added, were it not for certain fallacies the percentage would exceed 40. Others have recorded similar results.

With regard to the prevention of the disease, the methods to be adopted may be classed under two heads—administrative and medical. Obligatory notification is already adopted in many European countries, while in others, such as Great Britain, the machinery is all in readiness, and it requires little more than a stroke of the pen to include it among those which are already on the list. If this were done it would arouse public interest, it would secure proper treatment for the patient's eyes at the earliest possible moment, others would be safeguarded from infection, and exact statistics would become available.

It has been objected that notification would imply a slur on the parents' morality, and it is true this might be so if the gonococcus alone was responsible for all cases of ophthalmia in the newborn. This is not the case, for a fair number are due to other organisms; but even if this were the case, surely we have no right to neglect precautions which will certainly prevent blindness because we are afraid of casting a slur on the parents.

Every one should be instructed in the awful risk which is run when the disease is either not recognized or not treated adequately. No acute disease, perhaps, is so easily cured as is ophthalmia neonatorum. So much is this the case that an ophthalmic surgeon would consider it little short of a disgrace, either to himself or to those who were supposed to carry out his directions, if an eye were lost which had a clear and unulcerated cornea when he first saw it. In the case of children sufficiently robust to give them a reasonable chance of reaching adult age the eyes are saved in probably 99 per cent. or even more.

Whether Credé's prophylactic method of instilling a 2 per cent. or a 1 per cent. solution of silver nitrate in every child's eye directly after birth should be adopted in all cases is a matter which admits of some discussion. A large number of cases treated in fifteen Continental maternity hospitals before the introduction of this method yielded an average of 4.05 per cent. of cases of ophthalmia neonatorum, afterwards the percentage fell to less than 1. It is probably at the present time the best prophylactic measure known, and the committee states its opinion that in lying-in hospitals and departments maintained at the public expense the routine employment of a 1 or even a 2 per cent. solution of silver nitrate is amply justified, since the public has a right to protect itself against the burden of preventable

blindness. The committee also recommends that in extern hospital and Poor Law practice the same solutions should be employed as a matter of routine. With regard to private patients, the committee considers that some measure of prevention, be it aseptic or antiseptic, should be adopted in the case of every infant born alive, and that when earlier infants of the same family have developed ophthalmia the application of an efficient antiseptic to the eyes as soon as possible after birth appears to be unconditionally indicated. The committee states that "cases of ophthalmia without adequate treatment have been found to occur amongst cases attended by medical practitioners, as well as amongst those attended by 'midwives,' and it cannot be doubted that every possible means should be taken to ensure that all medical men, all nurses, all mothers, and in fact every one who is likely to be employed in attending a woman in her confinement, should be able to recognize the disease at once, and to know the importance and the nature of the steps which should be taken, without the least delay, so soon as any discharge is seen in the baby's eyes, or the fact that the mother has a leucorrhoea is recognized. There can be little doubt that this necessary knowledge would more speedily become general if the disease had to be notified. The result would be that hundreds and thousands of children would have eyesight who are at present doomed to permanent blindness, while the State and the charitable public would be spending pence where they are now spending pounds in keeping up institutions, and in keeping those who through blindness are incapable of maintaining themselves.

The valuable work done by the committee, under the able chairmanship of Mr. Sydney Stephenson, can be appreciated by any one who will read the report, which is full of interest not only to the medical profession, but to the public at large.

IMMUNIZATION AND RESPONSE IN INFECTIVE DISEASES.

In a paper recently read before the Royal Society of Medicine, and also published with additions in book form,¹ Dr. E. C. Hort discusses and criticizes the present treatment of infective diseases by means of bacterial vaccines. His thesis is that, whereas the production and maintenance of immunity to infection are generally considered to be questions of protection against the invading parasites and their products only, this interpretation ignores factors such as autolysis and other anomalies of cell metabolism, and the toxic products of those anomalies.

The direct methods at present employed for fighting bacterial diseases—the use of antitoxins, antiserums, and bacterial vaccines ("hetero-inoculations," as Dr. Hort names them)—are therefore on this hypothesis to be considered as partial measures; for the full defensive forces of the body to be called into operation, the preferable method would be to combine immunization to bacteria and their products with immunization to the products of altered cell metabolism and of tissue disintegration—"somatic products," as these may be termed. There can be little doubt that in spontaneous cure of infective diseases this actually takes place; in croupous pneumonia, for example, the autolysis of the exudate,

which is performed by somatic products, namely, enzymes, brings about resolution.²

Dr. Hort believes that by "auto-inoculation," in which the patient is inoculated with his own products, bacterial and somatic, Nature's methods may in many instances be more closely imitated than by hetero-inoculation. It has been shown by Sir Almroth Wright and his co-workers that in tuberculous disease for example, movement, active or passive, is accompanied by an auto-inoculation, as judged by alterations in the opsonic index. Wright admits that auto-inoculation presents some advantages over hetero-inoculation—for example, the correct vaccine must inevitably be employed, and the lymph at the site of a local infection impregnated with bacterial products is replaced by fresh lymph; but he considers that these advantages are outweighed by disadvantages, such as the impracticability of adjusting the dose of bacteria and their products, the possible dissemination of the infecting organism, etc.³ In these conceptions Wright considers bacteria and their products only, and does not appear to take into account the possibility that the somatic products derived from the tissues of the infected body play a part in the production of the disease syndrome.

The evidence that response in a bacterial infection is due both to bacteriotropic and to cellulotropic substances must necessarily be indirect, but a consideration of the following facts renders this view, to say the least, extremely probable. Various forms of cell degeneration are accompanied by the liberation of proteolytic ferments: albumosuria is not infrequent in extensive suppuration, in pneumonia, and in malignant disease in which the growths are undergoing softening and necrosis. The anaemia and cachexia of malignant disease in the early stage may with great probability be attributed to the action of the products of autolysis of the new growth. Ferments as a general rule give rise to pyrexia, and the intermediate products of ferment action are likewise pyrogenetic. In the autolysis of nerve substance choline is liberated, and may readily be converted into the highly toxic neurin. In extensive burns, in which death rapidly follows before the supervention of sepsis degenerative changes are found in the organs identical with those met with in acute infections,⁴ the cell destruction resulting from the burn being thus followed by the development of somatic products possessing toxic action comparable to that of a bacterial toxin. The fluid of an abscess is rich in tryptic ferments, and the normal antitryptic action of the serum has been shown to be increased in various infections indicating the liberation of tryptic ferment with a corresponding response, and the increased formation of antitrypsin. Therefore Dr. Hort is probably right when he maintains that the indications of response on the part of the body to an infection are indications of response not only to bacterial, but also to somatic products.

Conceding that vaccine therapy has achieved notable victories, at the same time it sometimes fails—how often we are, perhaps, not in a position to judge, as it is generally the successes, and not the failures, that are recorded. By vaccine therapy response to the bacterial part of the infection is alone evoked, and it therefore seems legitimate to conclude that in some cases at least, if response could also be evoked to the somatic part of the intoxication, increased benefit

would result. To achieve the latter by artificial means would appear to be a difficult task, but Dr. Hort believes it may be done by "auto-inoculation." The various measures that have been employed in the treatment of localized infections, such as poulticing, cupping, counter-irritation, and, more recently, Bier's methods of inducing hyperaemia and active and passive movement, act partly by determining a "flushing-out" action, partly by distributing the products, bacterial and somatic, throughout the body, so that they act as vaccines; in other words, these measures in part constitute a process of auto-inoculation. Time alone can show what method is the best for inducing reaction and response—whether hetero-inoculation or auto-inoculation, or a combination of the two; but Dr. Hort has made out a good case for a careful trial of "auto-inoculation."

It is desirable, whatever form of inoculation be employed, to have means of gauging the amount of response. Of these, the general condition of the patient, the progression or retrogression of the disease, as discerned by the clinician, goes for much, and cannot be neglected, in spite of the sneers sometimes levelled at it by the "laboratory" man. Opsonic determinations have also of late been much employed for the purpose, and, could they be relied on, might convey considerable information on the response—at least, to the bacterial part of the intoxication. It must be admitted, however, that the opsonic technique is laborious and extremely delicate; it often does not deal with the actual organism of the infection nor concern itself with possible variations in the phagocytic power of the leucocytes employed. Yet different strains of an organism do exhibit variations in their capacity for phagocytosis, and Shattock and Dudgeon⁵ assert that the leucocytic cells vary like the serum. Greenwood,⁶ from statistical considerations, estimates that opsonic determinations within the limits between 0.8 and 1.3 are probably unreliable for a count made on 25 cells, and doubts if samples of 50 or 100 cells give results of much greater accuracy. The fact that the opsonic index may alter as a result of movement—for example, walking to hospital—in consequence of auto-inoculation, and, lastly, the varying results obtained by different investigators working with the same serums, as recorded by Dr. Hort,⁷ indicate that very material uncertainty exists as regards opsonic determinations as at present carried out.

Dr. Hort places much reliance on the temperature curve, particularly a modified curve in which the evening temperatures alone are charted, as indicative of the response to auto-inoculation, and the illustrations he gives in his paper seem to bear out his contention. He moreover points out that in some cases of tuberculosis the absence of pyrexia, so far from being satisfactory, may indicate an absence of response and an actual progression of the disease.

Studies on the antityphoid power of the serum have recently been commented on in these columns,⁸ and variations in this factor may in future be of value both in the diagnosis of infective diseases and in the estimation of the amount of response to treatment.

This survey suggests that much remains to be elucidated before we shall be in a position completely to understand the nature of the disease

complex in an infection, that vaccine therapy by hetero-inoculation is not the final method of treatment, and that the indications derived from opsonic determinations must at present be accepted with a considerable degree of caution.

ANTITYPHOID INOCULATION.

THE current number of *Biometrika* contains a valuable study of inoculation statistics by Mr. G. D. Maynard of Pretoria.¹ By the help of biometric methods, Mr. Maynard has determined the relation between immunity from typhoid and inoculation and between the latter and recovery from the disease when incurred.

With respect to the first point, the result is that while the figures from the Transvaal show no association between immunity and inoculation, the correlation coefficients being actually negative, the figures for two sets of Indian data give an appreciable positive value (0.2395 ± 0.0118 , 0.2556 ± 0.0095) and the 17th Lancers (Indian experience) and Coldstream Guards (Cairo experience) yield a moderately high correlation (0.8502 ± 0.0593 , 0.4987 ± 0.0577). Material bearing on the problem whether inoculation modifies the disease if subsequently acquired was less extensive and the coefficients obtained were not significant, having regard to their probable errors. Mr. Maynard was also unable to find any evidence in support of the contention that the protection conferred by inoculation does not attain its maximum at once. The author discusses the possible causes of the discrepancy between the results obtained from Indian and South African material, and is inclined to attribute it to a relatively greater frequency of paratyphoid infections in South Africa. Although the difference between paratyphoid and true typhoid organisms is, at the most, specific and not generic, this source of failure may quite well have influenced the result; those who recall a controversy in these columns a few years ago will remember that still grosser causes of error were alleged to exist in some of the South African returns.

In a note to this memoir, Professor Karl Pearson criticizes adversely the evidence afforded by the 17th Lancers' experience, and concludes that: "Until a far 'higher standard of statistical observation and 'statistical reduction is adopted, we cannot possibly 'call, with Lieutenant-Colonel Leishman, the report 'of Lieutenant Luxmore a striking piece of evidence 'as to the protective effect of the inoculations."

Professor Pearson's criticisms, like everything which emanates from so distinguished a statistician, deserve careful study, but we have not been able to satisfy ourselves that the arguments he adduces warrant quite so sweeping a condemnation. Professor Pearson condemns the inclusion in the returns of officers and their wives, who form about 13 per cent. of the inoculated group, and "whose environment and 'average age probably differ much from those of the 'non-commissioned officers and men." This defect would have been of more moment in the case of a native regiment, the officers of which are generally senior men, than in that of an English regiment stationed in India. It would have been interesting if the correlation had been re-worked, using Mr. Maynard's table, with a deduction of 13 per cent. from the subtotal of inoculated persons not attacked by typhoid,

⁵ *Proc. Roy. Soc. Lond. B.*, vol. lxxx, 1908, p. 165.

⁶ *Proc. Roy. Soc. Med.*, II, No. 5, 1909, Pathol. Sect., p. 145.

⁷ *BRITISH MEDICAL JOURNAL*, 1909, February 13th, p. 400.

⁸ *Ibid.*, 1909, February 20th, p. 489.

¹ *Statistical Study of Antityphoid Inoculation*. By G. D. Maynard F.R.C.S.E. *Biometrika*, vol. vi, part 4, pp. 366-376.

so that we could form some idea of the magnitude of the error possibly involved. To test the matter quickly, we recalculated the correlation from Mr. Maynard's table as it stands and from the table modified as suggested above, by means of the approximation, Q_3 . We found in this way that to deduct the officers and their wives reduced the correlation only by a little more than 6½ per cent., but unfortunately, owing to the magnitude of "h" and "k," the value of Q_3 differs widely from the true correlation, and the approximation ceases to be so useful for comparative purposes.

Professor Pearson goes on to contend that "the so-called 'controls' cannot be considered as true controls until it is demonstrated that the men who are most anxious and particular about their own health—the men who are most likely to be cautious and run no risk—are not the very men who will volunteer to be inoculated; thus a spurious correlation may be produced between attack and absence of inoculation. The age frequency of both classes ought to be further given in every report. Clearly, what is needed is the inoculation of one half only of the volunteers, equal age incidence being maintained, if we are to have a real control." Since the valuable papers of Dean and the Ledinghams much attention has been directed to the importance of typhoid carriers. We believe that expert opinion in India inclines to the view that contamination of food in preparation and of sanitary offices by typhoid carriers is a much more important source of regimental typhoid than casual infection. Should this be a correct view, the personal carefulness of the men can be of little moment as a means of prophylaxis. It may be remarked that the ideal control proposed by Professor Pearson is hardly likely ever to be carried out, however desirable such a consummation might be. Any one placed in authority who, while believing that antityphoid inoculation afforded some measure of protection against so grave a disease, refused to confer such protection upon volunteers, would take on himself a somewhat grave responsibility.

THE BUDGET

THE Budget proposals as they affect the medical profession are discussed on page 1133. As will be seen, it is difficult even for an expert confidently to anticipate the full effect of the proposals as they will work out in practice. It is not a great Budget, it does not contain any original ideas, and is no doubt largely the result of compromise, but on the whole it shows a desire to be just or at least lenient to men whose chief asset is mental and physical health. It seems probable that the income-tax proposals will not alter the position of the large majority of the members of the medical profession, while the fact that the rate on the earned portion of incomes between £2,000 and £3,000 a year still remains at 1s. or less than the full rate, will be appreciated by those who in middle life are reaping the reward of early exertions, although it does not, owing to the increase in the general rate, directly benefit them. The fresh inroad on unearned incomes, often incomes derived from savings very hardly earned, will be felt as an injustice, and will tend to induce many men to postpone the hour of retirement, for they will not only feel the immediate pressure, but will dread that the fatal facility with which the tax can be increased may lead to fresh encroachments on the provision they have been able to make for old age. The Chancellor of the Exchequer was, however, confronted by a financial position with which it was not

easy to deal, and the total amount of the deficit was no doubt only realized at the last moment, for the Budget bears obvious traces of haste. Otherwise, we imagine it would not have contained such a proposal as that to increase the duty on proof spirit without a proviso to exempt spirit used for medical and scientific purposes. It does not seem possible at present to determine what will be the net result of the new imposts on motor cars and petroleum, but the tentative calculations we have made render it probable that the extra cost to medical motorists will not be large even if they have to pay for petrol on the higher scale. On the whole, as the bystander said to the man who was ridden over by a troop of horse and found himself unscathed, there is much to be thankful for.

"AN UNSAVOURY EAT."

UNDER this heading we had occasion to comment in the JOURNAL of December 19th, 1903, p. 1831, on the highly unseemly manner in which a certain "beef juice" was advertised in a French publication entitled *Chantecleir*. That periodical, though ostensibly a "bimonthly journal," is in reality a trade circular in which the "beef juice" referred to is pushed by the help of coloured portraits of well-known members of the medical profession. The one on which we felt it our duty to remark was of a character that can only be called disgusting. Now our attention has again been called to the issue for April, in which a Spanish professor in his official robes is represented as demonstrating on a half-dissected girl, who is smoking a cigarette and apparently enjoying the procedure. The figure occupies the foreground, and of course the undissected side is shown. Without being actually indecent the picture is suggestive, and the accessories—the arm and breast and the skin of the leg, lying on an ornamental couch in the background—are in the worst possible taste. What strikes us most about the thing is its extreme silliness as a means of inducing people to buy the "beef juice" which it is intended to advertise. It is impossible to imagine that it is intended to convey the suggestion that the "beef juice" is made of the *dissecta membra* of the subject. Yet it would be difficult to say what else can be meant, unless we assume that the nude figure, hideous as it is in its crude realism, is intended to attract attention. We are glad to learn from a correspondent that he has brought the fact that the circular is sent about in an open cover to the notice of the Postmaster-General. The official reply is that the circular would not have been delivered if its character had been observed; and it is added that instructions have been given for a watch to be kept in case any other circulars of the same description are received. We said in our previous note on the subject that the firm responsible for the issue of these circulars might amend the error of its advertising ways, at least in this country, if it could be brought to realize that even the most wonderful "beef juice" could not be forced on the medical profession by means which produce disgust. It has not chosen to take the hint, but now that it has come under the ban of the Post Office its eyes may possibly be opened. The thanks of the profession are due to the practitioner who took the trouble to communicate with the Postmaster-General on the subject.

THE STAGE OF ROYALTY.

It will be a bad day for royalty when people cease to take an interest in its comings and goings, its sayings and its doings, its joys and its sufferings. The publicity is no doubt often inconvenient; but it is

better than the indifference with which a nation would regard the "cast iron king" suggested by Jean Paul Richter as a useful substitute for a human sovereign. The people, indeed, may claim a right to know when a possible heir to the throne is born and when a ruler is in danger of death; this was admitted by Sir Henry Hafford in his well-known pronouncement about bulletins. There are royal personages who hate the notion that anything about them smells of mortality, like poor Lear's hand; there have even been some who took it ill that it should be thought that kings were subject to death. Did not a tactless courtier have to explain away an allusion to *le feu roi d'Espagne* by saying it was a title they assumed? We have it also on the authority of a court official of a bygone day that a queen of Spain had no legs. At the present day a royal personage has the unenviable privilege of learning every detail of any disease he may be believed to suffer from, and to read of himself, as the Emperor Frederick might have done in an English newspaper, as "rotting on his throne." They are not allowed to be under any of the illusions as to their state that may be cherished by their poorest subjects. They are born, they live, and they die in public; their coming into the world and their going out of it are performances that must be gone through with the whole of civilized mankind looking on. Quite lately, before the happy event which has gladdened Holland, speculation and suspicion, if we are to believe the newspapers, were rife. Special correspondents hung about the doors and invaded the backstairs of the palace at La Hague. One scribe wrote: "The situation here is of an extraordinary character: After a day of painful excitement, of wild rumours, and of tumultuous scenes in the streets, a strange quietude reigns in The Hague. All day long men and women have been talking together gravely, filled with perplexity and gloomy feelings. It seems as if the old apathy had settled down upon the people; as if, indeed, the old days of indefinite expectation and patient waiting had begun all over again. Yet beneath this quietude there is profound emotion, an uneasiness which is not expressed so much in words as in faces full of apprehension." People were inclined to take it ill because the Queen seemed to be a little longer than she should have been in going through her part! The public mind was in the same state of excitement and suspense about the young Queen of Spain's first baby, and there were headshakings and hints of doubt among the quidnuncs as to what was to happen or whether anything was to happen. And all this because no one except those in attendance on the august ladies who were about to enter on their time of travail was in a position to know accurately when the event was to be expected. Fortunately for the leading actresses in these dramas it may be surmised that they were not allowed to learn that they were keeping the public waiting. But on the physicians, had they been of nervous temperament, what may figuratively be called the cries for the lifting of the curtain might have a disconcerting effect. Sovereigns who know human nature well are careful to encourage the doctor. When Dubois was anxious about Marie Louise at the time of the birth of the King of Rome, Napoleon told him to treat the Empress exactly as if she were a woman from the Faubourg St. Antoine. When Louis XIII was born apparently dead, and the midwife was distracted, Henry IV asked her to treat the child in the way she was accustomed to do in such cases. To most of us dying in public would add incalculably to the unpleasantness of the situation. But kings have to go through the per-

formance almost literally under the public eye. The old Emperor William seems to have been troubled by this in his last moments, for among the mutterings heard just before he passed away were the words *Zu viel Menschen* (Too many people). Nevertheless royalty is less constantly on the stage than it used to be when the Grand Monarque held his levees seated on a close stool. This is due to the change of manners, which has brought with it some impairment of the sense of the dignity that hedges about a throne.

SEWER AIR.

SINCE the time when the construction of sewers became general there has always been a more or less wholesome dread of "sewer air." That dread found expression by Sir John Simon, when in one of his classical reports to Local Government Board he wrote: "Fifth does not only infect where it stands, but can transmit its infective power afar by certain appropriate channels of conveyance."¹ The belief that specific diseases were transmitted through the air of sewers was rather rudely shaken some twenty years ago, when Carnelly and Haldane published the results of experiments they had made on the air in sewers connected with the Houses of Parliament and in Dundee. The conclusions they came to, and which were subsequently endorsed by Parry-Laws, were that the air of sewers was much better than might have been expected, and that it contained a much smaller number of organisms than any class of house. Not many years afterwards, however, a contrary opinion was expressed by Dr. David Arthur,² and only within the past year or two Horrocks and Andrewes have by independent investigation demonstrated that characteristic sewage bacteria are to be found in the air of sewers. About two years ago the Corporation of Manchester asked Professor Delépine to investigate the influence of sewer air upon health, and for that purpose there was constructed for him in the vicinity of the Public Health Laboratory grounds an experimental manhole and experimental rooms. In one of these rooms experiments could be carried on with garden air, and in the other with sewer air. During the whole of last year Professor Delépine conducted his investigations with the assistance of Drs. Sidebotham, Sellers, and Fowler, and of Mr. Gaul and Mr. Heap. The report which he has just issued discloses an amount of painstaking research on the part of all those concerned which is beyond praise. The investigations included observations and analyses relating to the flow, characters, and composition of sewage, their hourly, daily, and seasonal variations; the bacteriological examination of sewage and of sewer air; the examination of sewer air for the purpose of ascertaining whether it was contaminated with gases not normally present in sewers, and, lastly, experiments on animals. The conclusion to which Professor Delépine has come as the result of his observations is that the air of a fairly well-constructed sewer carrying moderately dilute sewage of average composition is free from appreciable noxious properties. He is careful to qualify this opinion by saying that it is not applicable to the air of sewers where, owing to the formation of deposits, or for some other reason, the air has become loaded with an unnecessary amount of noxious gases not usually present under other conditions; nor does it apply to sewers receiving certain kinds of trade effluents or waste products, nor to the air escaping from foul drains or pipes, which air may be quite different from sewer air, or may

¹ Public Health Reports of John Simon. Edited by E. Seaton. Vol. II, p. 464.

contain particles of dried material not to be found in sewer air. He considers that in all probability the bad effects which have at various times been attributed to sewer air should have been considered as due to changes in the sewage which need not have taken place, or to admixture with noxious products which might have been prevented.
